A directory of higher G-algebra

Natalie Stewart

August 10, 2024

Contents

The purpose of the following document is to serve as a directory to a large swath of the current knowledge concerning *genuine equivariantly homotopy coherent algebra*. The reader should interpret this as inherently limited to those papers which the contributors have happened to find, which at the present is just the author.

Remark. Throughout this text, we embrace a linguistic dichotomy regarding homotopy-coherent algebra: that which is founded in 1-categories with auxiliary structure (homotopical categories, model categories, etc.) is called *brave new algebra* (following Waldhausen's coinage), and that which is founded in ∞-categories is called *higher algebra* (following Lurie's coinage). Seeing as this text is not called "A directory of brave new G-algebra," we restrict our focus almost exclusively to equivariant higher algebra. $\triangleleft$

Any errors belong to the author. If any errata or missing references are found, please direct them to her, or ask her for edit permissions.

This is a work in progress!

Part I

HA index

Chapter 1

Stable ∞-categories

The major reference for this section is [Nar16].

1.1 Foundations

- HA.1.1.2.14 follows for the fibers of $\mathcal{T}$-categories by noting that $\mathcal{T}$-stability implies fiberwise stability [Nar16, Def 7.1].

1.2 Stable ∞-categories and homological algebra

I don't know of G-references for any of this section.

1.3 Homological algebra and derived categories

I don't know of G-references for any of this section.

1.4 Spectra and stabilization

- HA.1.4.1.10: I don't know of a reference for this.
- HA.1.4.2.14: I don't know of a reference for this.
- HA.1.4.2.17: this follows for $\mathcal{T}$ by [Nar16, Lem 7.2].
- HA.1.4.2.23: this follows for $\mathcal{T}$ by [Nar16, Thm 7.4].
- HA.1.4.2.27: this follows for $\mathcal{T}$ under the additional assumption that the category is $\mathcal{T}$-semiadditive by [NS22, Def 7.1].
- Section 1.4.3: I don't know of any references on equivariant t-structures.
- HA.1.4.4.2 may follow for $\mathcal{T}$ from the presentable-idempotents equivalence of [Hil24, Thm 6.5.4] combined with a version of the characterization of $\mathcal{T}$-stable Ind-completions of [Hil24, Prop 5.2.3]. In general, results from [Hil24, § 6] should help.
- HA 1.4.4.4-1.4.4.6 should probably follow by adding $\mathcal{T}$ to the HA proof using the $\mathcal{T}$-AFT of [Hil24, Thm 6.2.1]; it is worth noting that the $\mathcal{T}$-category of $\mathcal{T}$-spectra is probably presentable by a combination of [NS22, Thm 7.4] and a version of [Hil24, Lem 6.7.4] for linear functors.

Chapter 2

∞-operads

The major references for this section are [CH21; CH23; Hau23; NS22].

2.1 Foundations

Section 2.1 is relitigated for $\mathcal{T}$ in [NS22, § 2], and modernized in [BHS22; CH21; CH23].

2.2 Constructions of ∞-operads

- HA.2.2.1 for $\mathcal{T}$ is [NS22, § 2.9]
- HA.2.2.2 will appear in upcoming work of mine concerning the BV indexed tensor product.
- I don't know of a reference for HA.2.2.3.
- HA.2.2.4 for $\mathcal{T}$ is [NS22, § 2.8] and it is modernized in [BHS22].
- HA.2.2.5 appears in some guise in [Bar18]; I plan to cover this for $\mathcal{T}$ in upcoming work concerning BV tensor products of $\mathcal{N}_\infty$ and $\mathbb{E}_V$ G-operads. Nevertheless, the associated *internal hom* was constructed in [NS22, § 5.3], and a proof that it is left adjoint to the "obvious" definition of binary G-BV tensors appears in some lecture notes of mine.
- HA.2.2.6 for $\mathcal{T}$ is [NS22, § 3].

2.3 Disintegration and assembly

Approximation of ∞-operads is modernized in [BHS22, § 5], but otherwise I don't know references for HA.2.3.

2.4 Products and coproducts

1. HA.2.4.1: the construction of cartesian Symmetric monoidal structures for $\mathcal{T}$ appears as [NS22, Ex 2.4.1], but I don' know of an existing reference for HA 2.4.1.8-2.4.1.9; this will appear for I-operads in my upcoming work on $\mathcal{N}_\infty$-operads, where I is an indexing system.
2. I don't know of a reference for HA.2.4.2.5, but this is not hard to show in general.
3. HA.2.4.3.9 and its consequences will appear in upcoming work of ine about $\mathcal{N}_\infty$-operads.
4. I don't know of any reference for HA.2.4.4.

Chapter 3

Algebras and modules of ∞-operads

3.1 Free algebras

- HA.3.1.1-2 seems to be developed for $\mathcal{T}$ in [NS22, § 4].
- HA.3.1.3 seems to be developed for $\mathcal{T}$ as [NS22, Thm 4.3.4]; we will develop the practical computation of the monad associated with algebras in a distributive G-symmetric monoidal category in upcoming work in $\mathcal{N}_\infty$ operads (c.f. [SY19, Lem 2.4.2])

3.2 Limits and colimits of algebras

- HA 3.2.1 is [NS22, § 5.2].
- Much of HA 3.2.2-3.2.3 may be summarized by [NS22, Cor 5.1.5].
- HA 3.2.4.7 is kind of developed for I as [NS22, Cor 5.3.8], so long as "is cocartesian" is interpreted as "is a cocartesian structure;" we prove that this identifies the I-symmetric monoidal structure in upcoming work on $\mathcal{N}_\infty$-operads using an I-lift of HA 2.4.1.8-2.4.1.9.

3.3 Modules over ∞-operads

Upcoming!

3.4 General features of module ∞-categories

Upcoming!

Chapter 4

Associative algebras and their modules

(to be filled later, but it's mostly missing)

Chapter 5

Little cubes and factorizable sheaves

5.1 Definitions and basic properties

- I know of neither a reference nor a precise statement for HA.5.1.1.1.
- HA.5.1.1.4 is lifted to $\mathbb{E}_V$ as the main theorem of [Ste24], and HA.5.1.1.5 immediately follows.
- HA.5.1.1.7 is lifted to $\mathbb{E}_V$ in [Ste24].
- I know of no (homotopical) reference for HA.5.1.2.1, and it is likely to be quite difficult; I expect to resolve this in the spectral setting in upcoming work.
- I know of no reference for HA.5.1.3-HA.5.1.5

5.2 Bar constructions and Koszul duality

(to be filled later, but it's mostly missing)

5.3 Centers and centralizers

(to be filled later, but it's mostly missing)

5.4 Little cubes and manifold topology

(to be filled in later, see [Hor19])

5.5 Topological Chiral homology

(to be filled in later, see [Hor19])

Chapter 6

The calculus of functors

(to be filled later, but it's mostly missing)

Chapter 7

Algebra in the stable homotopy category

(to be filled in later, but it's mostly upcoming)

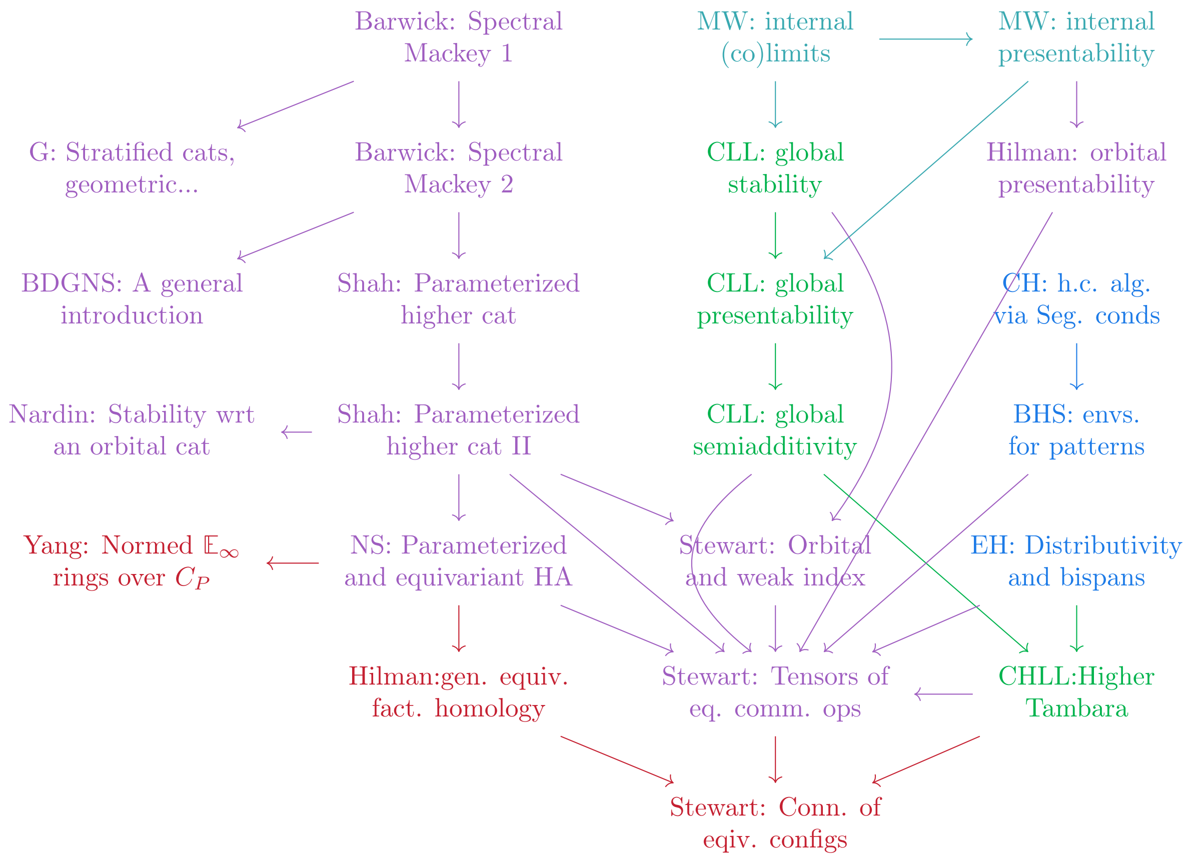
Chapter 8

A graph of dependencies in the literature



Part II

The work of Barwick-Dotto-Glasman-Nardin-Shah

The ∞-categorical perspective on equivariant homotopy perhaps first began in the two papers of Barwick and Barwick-Glasman-Shah on spectral Mackey functors (i.e. G-spectra, when G is finite). This is where we first see the *effective burnside category* come clearly into view in ∞-category theory, defined functorially for arbitrary *disjunctive triples*, and with compatibility with certain fibrations via the *unfurling construction*.

Following this, the writing of book was declared by Barwick-Dotto-Glasman-Nardin-Shah, fleshing out Hill's program (c.f. [HH16]) for equivariant algebra in the ∞-categorical perspective, to be distributed first as a sequence of 9 exposés. In retrospect, around half of these were finished, and it doesn't appear that the members are still publishing papers are still publishing in stable equivariant homotopy.

Nevertheless, several immensefully useful papers were developed; of particular note are Glasman's paper on isotropy separation over (epi)orbital categories, Shah's two papers thoroughly covering equivariant higher category theory, Nardin's paper on equivariant stability, and Nardin-Shah's paper covering some rudiments of equivariant operads.

SPECTRAL MACKEY FUNCTORS AND EQUIVARIANT ALGEBRAIC K-THEORY (I)

CLARK BARWICK

For my dear friend Dan Kan.

Abstract. *Spectral Mackey functors* are homotopy-coherent versions of ordinary Mackey functors as defined by Dress. We show that they can be described as excisive functors on a suitable ∞-category, and we use this to show that universal examples of these objects are given by algebraic K-theory.

More importantly, we introduce the *unfurling* of certain families of Waldhausen ∞-categories bound together with suitable adjoint pairs of functors; this construction completely solves the homotopy coherence problem that arises when one wishes to study the algebraic K-theory of such objects as spectral Mackey functors.

Finally, we employ this technology to lay the foundations of equivariant stable homotopy theory for profinite groups; the lack of such foundations has been a serious impediment to progress on the conjectures of Gunnar Carlsson. We also study fully functorial versions of A-theory, upside-down A-theory, and the algebraic K-theory of derived stacks.

Contents

0. Summary

This paper lays the foundations of what might be called *axiomatic derived representation theory*. Inspired by Bert Guillou and Peter May [11, 12, 13] and Dmitry Kaledin [18], we construct here a very general homotopy theory of *spectral Mackey functors* — families of spectra equipped with operations that mirror the restriction and induction operations found in ordinary Mackey functors. Our theory of spectral Mackey functors accounts for all of the compositions of these operations, their homotopies, their homotopies between homotopies, etc.

The basic input is an ∞-category C with two subcategories, $C_{\dagger} \subset C$, whose maps we call *ingressive*, and $C^{\dagger} \subset C$, whose maps we call *egressive*. We require that ingressive and egressive maps are stable under pullback, and we require that C admit finite coproducts that act effectively as disjoint unions (Df. 5.2). We call this a *disjunctive triple* $(C, C_{\dagger}, C^{\dagger})$.

Example. The ordinary category of finite continuous G-sets for a profinite group G defines a disjunctive triple in which every morphism is both ingressive and egressive.

Example. The ordinary category of varieties over a field defines a disjunctive triple in which every morphism is egressive but only flat and proper maps are ingressive.

Example. The ∞-category of spaces defines a disjunctive triple in which every morphism is ingressive but only morphisms with finite (homotopy) fibers are egressive.

The names "ingressive" and "egressive" are meant to suggest functorialities: a spectral Mackey functor M on C should consist of a covariant functor

$$M_{\star} \colon C_{\dagger} \longrightarrow \mathbf{Sp}$$

and a contravariant functor

$$M^{\star} \colon (C^{\dagger})^{op} \longrightarrow \mathbf{Sp},$$

each valued in the ∞-category $\mathbf{Sp}$ of spectra. These functors will be required to carry coproducts to wedges of spectra. These two functors will agree on objects, so that given a map $f \colon X \longrightarrow Y$, we obtain a *pullback* map

$$f^{\star} \colon M(Y) = M^{\star}(Y) \longrightarrow M^{\star}(X) = M(X)$$

and a *pushforward* map

$$f_{\star} \colon M(X) = M_{\star}(X) \longrightarrow M_{\star}(Y) = M(Y).$$

Furthermore, the pullback and pushforward maps are required to satisfy a *base change condition*; namely, for any pullback square

$$\begin{array}{ccc} X' & \xrightarrow{f} & Y' \\ {\scriptstyle g}\downarrow & & \downarrow{\scriptstyle g} \\ X & \xrightarrow[f]{} & Y \end{array}$$

(with abusively named morphisms), we require that

$$g^{\star} f_{\star} \simeq f_{\star} g^{\star}.$$

But this description won't quite do as a definition of Mackey functors. After all, the base change condition is no condition at all: the homotopies $g^{\star} f_{\star} \simeq f_{\star} g^{\star}$

are additional *data*, and these data have to satisfy additional coherences, which themselves are homotopies that in turn have to satisfy further coherences, etc., etc., ad infinitum. To encode all this data efficiently, we define the *effective Burnside ∞-category* $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)$ (Df. 5.7). The objects of this ∞-category are the objects of C, and a morphism from X to Y in $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)$ is a span

$$\begin{array}{ccc} & U & \\ \swarrow & & \searrow \\ X & & Y, \end{array}$$

in C in which $U \twoheadrightarrow X$ is egressive and $U \rightarrowtail Y$ is ingressive. Composition is then defined by forming pullbacks. Of course, pullbacks are only unique up to a contractible choice, so composition in $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)$ is only defined up to a contractible choice. This is no cause for concern, however, as this is exactly the sort of thing ∞-categories were designed to handle gracefully. In particular, even when C is an ordinary category, $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)$ typically won't be.

Now the ∞-category $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)$ has direct sums (Pr. 4.3 and 5.8), which are given by the coproduct in C, and a *spectral Mackey functor* on $(C, C_\dagger, C^\dagger)$ is a functor

$$A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \longrightarrow \mathbf{Sp}$$

that carries this direct sum to the wedge of spectra (Df. 6.1). When C is the category of finite G-sets for some finite group G, a spectral Mackey functor on C is tantamount to a genuine G-equivariant spectrum. (This is a theorem of Guillou and May [12].) If we replace the ∞-category of spectra in this discussion with an ordinary abelian category A, then we recover the usual notion of Mackey functors for G with values in A in the sense of Dress [4]. So the homotopy groups of a spectral Mackey functor form an ordinary Mackey functor in abelian groups, just as one would expect. (We will actually formulate our definition in terms of general target additive ∞-categories.)

If C is the ordinary category of finite G-sets for some finite group G, the homotopy category $hA^{\mathit{eff}}(C)$ of the effective Burnside ∞-category is not quite what one would typically call the Burnside category. Rather, the Burnside category is obtained by forming the group completion of the Hom sets — the "local group completion" — of $A^{\mathit{eff}}(C)$. (This is the significance of the word "effective" here; it's meant as a loose pun on the phrase "effective divisor.") Since our target ∞-categories will be additive and thus already locally group complete, however, the local group completion of $A^{\mathit{eff}}(C)$ is a layer of complication we can do without.

The main result of this paper is the discovery that there is a deep connection between algebraic K-theory and the homotopy theory of spectral Mackey functors. We show that spectral Mackey functors can be described as excisive functors from a certain "derived Burnside ∞-category" (Lm. 7.3). This identification allows us to use the Goodwillie differential [10] to construct *Mackey stabilizations* of functors from $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)$ to the ∞-category **Kan** of spaces (Pr. 7.4). It turns out that this use of the Goodwillie differential can in important cases be related (§9) to the use of the Goodwillie differential in our characterization of algebraic K-theory [2]. This little observation permits us to express *representable* Mackey functors $\mathbf{S}^X$ as *equivariant algebraic K-theory spectra.* The spectral Mackey functor $\mathbf{S}$ represented by the terminal object 1 is called the *Burnside Mackey functor* (Df. 8.1); it is the analog of the sphere spectrum in this context. (In a sequel to this work, we will show that in fact it is the unit for the natural symmetric monoidal structure on Mackey functors.) Our formula for the Mackey stabilization gives us a K-theoretic interpretation of this Mackey functor (§13).

More importantly, we solve the central homotopy coherence problem of equivariant algebraic K-theory: we prove that the algebraic K-theories of a family of Waldhausen ∞-categories [2] connected by suitable adjoint pairs of functors together define a spectral Mackey functor. This we do via an operation we call *unfurling* (Df. 11.3). The resulting structure provides a complete accounting for the functorialities enjoyed by the algebraic K-theory of such a family of Waldhausen ∞-categories.

The structure of a spectral Mackey functor is a very rich one, and it may be difficult to appreciate its utility from the abstract formalism alone. Therefore, in a sequence of appendices, we have the pleasure of studying our examples in some detail. Readers may find it useful to flip back and forth between bits of the body of the paper and these examples.

(A) The full subcategory of a coherent n-topos in the sense of Lurie ($1 \leq n \leq \infty$) spanned by the coherent objects is a disjunctive triple in which every morphism is both ingressive and egressive (Ex. A.2). If, moreover, every coherent object can be written as a coproduct of finitely many *connected objects* (Df. A.7), then our K-theoretic description of the Burnside Mackey functor $\mathbf{S}$ gives us a formula:

$$\mathbf{S}(1) \simeq \bigvee_X \Sigma^\infty_+ B\,\mathrm{Aut}(X),$$

where the wedge is taken over all equivalence classes of connected objects X, and $\mathrm{Aut}(X)$ denotes the space of auto-equivalences of X (Th. A.9). This is a very general form of the *Segal–tom Dieck splitting*.

(B) Suppose G a profinite group. Then the (nerve of the) ordinary category of finite continuous G-sets (i.e., finite sets with an action of G whose stabilizers are all open) is an example of the kind above. In particular, we may speak of spectral Mackey functors for G. When G is finite, it follows from work of Bert Guillou and Peter May [12] that the homotopy theory of spectral Mackey functors is equivalent to the homotopy theory of G-equivariant spectra in the sense of Lewis–May–Steinberger [24], Mandell–May [32], and Hill–Hopkins–Ravenel [14, 16, 15]. For general profinite groups, we believe that our ∞-category of spectral Mackey functors for G is the first definition of the homotopy theory of G-equivariant spectra. (The lack of foundations for such a subject has been a serious impediment to real progress on the conjectures of Gunnar Carlsson.) The generalized Segal–tom Dieck splitting (Th. A.9) gives a formula for the G-fixed points of the G-equivariant sphere spectrum:

$$\mathbf{S}^G_G \simeq \bigvee_H \Sigma^\infty_+ B(N_G H/H),$$

where the wedge is taken over conjugacy classes of open subgroups $H \leq G$, and $N_G H$ denotes the normalizer of H in G (Pr. B.8).

(C) For any space X, there are two kinds of conditions one might impose on a retractive spaces $X \longrightarrow X' \longrightarrow X$ (Nt. C.9): one could demand that X' is a retract of a finite CW complex (or, alternately, a finite CW complex itself); alternately, one could demand that the homotopy fibers of $X' \longrightarrow X$ are retracts of finite CW complexes (or, alternately, finite CW complexes). The algebraic K-theories of these ∞-categories are spectra denoted $\mathbf{A}(X)$ and $\mathbf{V}(X)$. The former is covariantly functorial and the latter is contravariantly functorial. But each possesses additional functorialities: if $X \longrightarrow Y$ is a map whose homotopy fibers are retracts of finite CW complexes, then we obtain umkehr maps $\mathbf{A}(Y) \longrightarrow \mathbf{A}(X)$ and $\mathbf{V}(X) \longrightarrow \mathbf{V}(Y)$. We can assemble these functorialities together to get Mackey functors $\mathbf{A}$ (respectively, $\mathbf{V}$) for the disjunctive triple given by the ∞-category of spaces in which every map is ingressive (resp., egressive), and only those maps whose homotopy fibers are retracts of finite CW complexes are egressive (resp., ingressive) (Nt. C.11). This provides a host of interesting *assembly maps* (C.12)

$$\mathbf{A}^{\oplus}(X,Y) \wedge \mathbf{A}(X) \longrightarrow \mathbf{A}(Y) \quad \text{and} \quad \mathbf{A}^{\oplus}(X,Y) \wedge \mathbf{V}(Y) \longrightarrow \mathbf{V}(X),$$

where $\mathbf{A}^{\oplus}(X,Y)$ is the group completion of the E_∞ space of diagrams

$$X \longleftarrow U \longrightarrow Y,$$

where the homotopy fibers of $U \longrightarrow X$ are finite CW complexes, and the E_∞ structure is given by coproduct. When $X = *$, the maps $\mathbf{S} \longrightarrow \mathbf{A}(*) \longrightarrow \mathbf{S}$ can be composed with these assembly maps to obtain, for any retract U of a finite CW complex, maps

$$\Sigma^\infty_+ \operatorname{Map}(U,Y) \longrightarrow \mathbf{A}(Y) \quad \text{and} \quad \Sigma^\infty_+ \operatorname{Map}(U,Y) \longrightarrow D\mathbf{V}(Y).$$

Dually, when $Y = *$, we obtain, for any space V, maps

$$\Sigma^\infty_+ \operatorname{Map}_{\mathrm{rc}}(X,V) \longrightarrow D\mathbf{A}(X) \quad \text{and} \quad \Sigma^\infty_+ \operatorname{Map}_{\mathrm{rc}}(X,V) \longrightarrow \mathbf{V}(X),$$

where $\operatorname{Map}_{\mathrm{rc}}$ denotes the space of maps whose homotopy fibers are retracts of finite CW complexes. Special cases of these maps have been constructed by Waldhausen, Malkiewich, and others. Moreover, it turns out that all of this holds when the ∞-category of spaces is replaced with any compactly generated ∞-topos whose terminal object is compact.

(D) In [2, §12], we defined the algebraic K-theory of derived stacks, and we observed there that it was contravariantly functorial in morphisms of (nonconnective) spectral Deligne–Mumford stacks. Here we push this further by including the covariant functoriality of the algebraic K-theory of spectral Deligne–Mumford stacks in certain and its compatibility with the contravariant functoriality. More precisely, we construct two disjunctive triples of derived stacks. The first is the ∞-category of spectral Deligne–Mumford stacks in which we declare that every morphism is egressive, and a morphism is ingressive if and only if it is strongly proper, of finite Tor-amplitude, and locally of finite presentation (D.17). The second is the ∞-category of all flat sheaves (of spaces) on the ∞-category of connective E_∞ rings in which we declare that every morphism is egressive, and a morphism is ingressive if and only if it is quasi-affine representable and *perfect* in the sense that the pushforward of the structure sheaf is perfect (Pr. D.20). We prove that algebraic K-theory is a spectral Mackey functor for each of these disjunctive triples (Nt. D.19 and Nt. D.22). This can be thought of as a very general and very structured form of proper base change for K-theory. It also ensures the existence of interesting *assembly maps*

$$\mathbf{A}^{\oplus}_{\mathrm{DM}}(X,Y) \wedge \mathbf{K}(X) \longrightarrow \mathbf{K}(Y) \quad (\text{respectively, } \mathbf{A}^{\oplus}_{\mathrm{Shv}}(X,Y) \wedge \mathbf{K}(X) \longrightarrow \mathbf{K}(Y)\ ),$$

where $\mathbf{A}^{\oplus}_{\mathrm{DM}}(X, Y)$ (resp., $\mathbf{A}^{\oplus}_{\mathrm{Shv}}(X, Y)$) is the group completion of the E_∞ space of diagrams

$$X \longleftarrow U \longrightarrow Y$$

of spectral Deligne–Mumford stacks (resp., of flat sheaves), where $U \longrightarrow Y$ is strongly proper, of finite Tor-amplitude, and locally of finite presentation (resp., quasi-affine representable and perfect), and the E_∞ structure is given by coproduct. When $X = \operatorname{Spec} \mathbf{S}$, the maps $\mathbf{S} \longrightarrow \mathbf{K}(\mathbf{S}) \longrightarrow \mathbf{S}$ can be composed with these assembly maps to obtain, for any spectral Deligne–Mumford stack (resp., any flat sheaf) U, maps

$$\Sigma^\infty_+ \operatorname{Map}_{\mathrm{pr}}(U, Y) \longrightarrow \mathbf{K}(Y) \quad \text{and} \quad \Sigma^\infty_+ \operatorname{Map}_{\mathrm{perf}}(U, Y) \longrightarrow \mathbf{K}(Y),$$

where $\operatorname{Map}_{\mathrm{pr}}(U, Y)$ (resp., $\operatorname{Map}_{\mathrm{perf}}(U, Y)$) denotes the space of morphisms $U \longrightarrow Y$ that are strongly proper, of finite Tor-amplitude, and locally of finite presentation (resp., quasi-affine representable and perfect). Dually, when $Y = *$, we obtain, for any spectral Deligne–Mumford stack (resp., any flat sheaf) V that is strongly proper, of finite Tor-amplitude, and locally of finite presentation (resp., quasi-affine representable and perfect) over $\operatorname{Spec} \mathbf{S}$, maps

$$\Sigma^\infty_+ \operatorname{Map}(V, X) \longrightarrow D\mathbf{K}(X) \quad \text{and} \quad \Sigma^\infty_+ \operatorname{Map}(V, X) \longrightarrow D\mathbf{K}(X).$$

Restricting this to étale covers of a fixed (nice) scheme X with a geometric point $x \in X(\Omega)$, we obtain the *Galois equivariant K-theory spectrum* (Ex. D.24)

$$K_{\pi_1^{\text{ét}}(X,x)}(X) \colon B^{fin}_{\pi_1^{\text{ét}}(X,x)} \longrightarrow \mathbf{Sp}.$$

In a very precise manner, this object encodes the failure of K-theory to satisfy Galois descent; this is the subject of a series of conjectures of Gunnar Carlsson [3], which can now be formulated thanks to the foundations we provide here. We intend to study this object in great detail in future work.

Related work. It is probably safe to say that others have anticipated a fully ∞-categorical (and thus "model-independent") construction of equivariant stable homotopy theory, but, as always, the devil is in the details. We believe this is the first ∞-categorical approach to equivariant stable homotopy theory, and it is the first to provide a complete construction of equivariant algebraic K-theory of families of Waldhausen ∞-categories of the kind described above. There are, however, a number of precursors to this paper.

In a brilliant series of papers, Bert Guillou and Peter May construct [11, 12, 13] a homotopy theory of spectral Mackey functors, and they show that for a finite group G, the homotopy theory of spectral Mackey functors for finite G is equivalent to the homotopy theory of genuine G-spectra. Our homotopy theory of spectral Mackey functors for finite G-sets is easily seen to be equivalent to theirs.

Dmitry Kaledin has also developed [18] a theory of "derived Mackey functors" (again for finite groups G). Our work here is a generalization of Kaledin's: the homotopy category of Mackey functors valued in the derived ∞-category of abelian groups is naturally equivalent to his derived category of Mackey functors.

Aderemi Kuku, extending work of Andreas Dress [5], has worked for many years on the foundations of equivariant higher algebraic K-theory as a construction that yields ordinary abelian group-valued Mackey functors (partly joint with Dress) [6, 7, 19, 20, 21, 22, 23]. For Mackey functors for finite groups, our work can be understood as lifting the target of Kuku's constructions to the ∞-category of spectrum-valued Mackey functors.

Work of Shimakawa [34, 35, 36, 37, 38] shows that the K-theory of permutative categories with a suitable action of a finite group can be given the structure of a genuine G-spectrum. The work here amounts to the generalization of this result to the context of Waldhausen K-theory for ∞-categories with suitable G-actions.

Mona Merling has an alternate approach to constructing G-spectra from Waldhausen categories with a suitable action of a finite group G. It is possible that her approach and the one given here are suitably equivalent; however, it seems that the two approaches differ significantly in the details, and Merling's appears to be adapted to the technology of equivariant homotopy theory as developed by Lewis–May–Steinberger [24], Mandell–May [32], and Hill–Hopkins–Ravenel [14, 16, 15].

Acknowledgments. I have had very helpful conversations with David Ayala and Haynes Miller about the contents of this paper and its sequels.

1. Preliminaries on ∞-categories

In general, we use the terminology from [25, 2, 1]. We review some of the relevant notation here.

1.1. **Notation.** In order to deal gracefully with size issues, we'll use Grothendieck universes in this paper. In particular, we fix, once and for all, three uncountable, strongly inaccessible cardinals $\kappa_0 < \kappa_1 < \kappa_2$ and the corresponding universes $\mathbf{V}_{\kappa_0} \in \mathbf{V}_{\kappa_1} \in \mathbf{V}_{\kappa_2}$. Now a set, simplicial set, category, etc., will be said to be ***small*** if it is contained in the universe $\mathbf{V}_{\kappa_0}$; it will be said to be ***large*** if it is contained in the universe $\mathbf{V}_{\kappa_1}$; and it will be said to be ***huge*** if it is contained in the universe $\mathbf{V}_{\kappa_2}$. We will say that a set, simplicial set, category, etc., is ***essentially small*** if it is equivalent (in the appropriate sense) to a small one.

1.2**.** The model of ∞-categories we will employ is Joyal's model of *quasicategories*, which we will here call ***∞-categories***. We refer systematically to [25] for details about this model of higher categories.

1.3. **Notation.** A ***simplicial category*** — that is, a category enriched in the category of simplicial sets — will frequently be denoted with a superscript $(-)^{\Delta}$.

Suppose $\mathbf{C}^{\Delta}$ a simplicial category. Then we write $(\mathbf{C}^{\Delta})_0$ for the ordinary category given by taking the 0-simplices of the Mor spaces. That is, $(\mathbf{C}^{\Delta})_0$ is the category whose objects are the objects of $\mathbf{C}$, and whose morphisms are given by

$$(\mathbf{C}^{\Delta})_0(x,y) := \mathbf{C}^{\Delta}(x,y)_0.$$

If the Mor spaces of $\mathbf{C}^{\Delta}$ are all fibrant, then we will often write

$$\mathbf{C} \quad \text{for the simplicial nerve} \quad N(\mathbf{C}^{\Delta})$$

[25, Df. 1.1.5.5], which is an ∞-category [25, Pr. 1.1.5.10].

1.4. **Notation.** For any ∞-category A, there exists a simplicial subset $\iota A \subset A$, which is the largest Kan simplicial subset of A [25, 1.2.5.3]. We shall call this space the ***interior ∞-groupoid of*** A. The assignment $A \longmapsto \iota A$ defines a right adjoint ι to the inclusion functor u from Kan simplicial sets to ∞-categories.

1.5. **Notation.** The large simplicial category $\mathbf{Kan}^{\Delta}$ is the category of small Kan simplicial sets, with the usual notion of mapping space. The large simplicial category $\mathbf{Cat}_{\infty}^{\Delta}$ is defined in the following manner [25, Df. 3.0.0.1]. The objects of $\mathbf{Cat}_{\infty}^{\Delta}$ are small ∞-categories, and for any two ∞-categories A and B, the morphism space

$$\mathbf{Cat}_{\infty}^{\Delta}(A,B) := \iota\,\mathrm{Fun}(A,B)$$

is the interior ∞-groupoid of the ∞-category $\mathrm{Fun}(A,B)$.

Similarly, for any strongly inaccessible cardinal τ, we may define the locally τ-small simplicial category $\mathbf{Kan}(\tau)^{\Delta}$ of τ-small simplicial sets and the locally τ-small simplicial category $\mathbf{Cat}_{\infty}(\tau)^{\Delta}$ of τ-small ∞-categories.

2. The twisted arrow ∞-category

We have elsewhere [] spoken of the twisted arrow ∞-category of an ∞-category. Let us recall the basic facts here.

2.1. **Proposition.** *The following are equivalent for a functor $\theta\colon \Delta \longrightarrow \Delta$.*

(2.1.1) The functor $\theta^{op}\colon N\Delta^{op} \longrightarrow N\Delta^{op}$ is cofinal in the sense of Joyal [25, Df. 4.1.1.1].

(2.1.2) The induced endofunctor $\theta^{\star}\colon s\mathbf{Set} \longrightarrow s\mathbf{Set}$ on the ordinary category of simplicial sets (so that $(\theta^{\star}X)_n = X_{\theta(n)}$) carries every standard simplex Δ^m to a weakly contractible simplicial set.

(2.1.3) The induced endofunctor $\theta^{\star}\colon s\mathbf{Set} \longrightarrow s\mathbf{Set}$ on the ordinary category of simplicial sets is a left Quillen functor for the usual Quillen model structure.

Proof. By Joyal's variant of Quillen's Theorem A [25, Th. 4.1.3.1], the functor θ^{op} is cofinal just in case, for any integer $m \geq 0$, the nerve $N(\theta/\mathbf{m})$ is weakly contractible. The category $(\theta/\mathbf{m})$ is clearly equivalent to the category of simplices of $\theta^{\star}(\Delta^m)$, whose nerve is weakly equivalent to $\theta^{\star}(\Delta^m)$. This proves the equivalence of the first two conditions.

It is clear that for any functor $\theta\colon \Delta \longrightarrow \Delta$, the induced functor $\theta^{\star}\colon s\mathbf{Set} \longrightarrow s\mathbf{Set}$ preserves monomorphisms. Hence $\theta^{\star}$ is left Quillen just in case it preserves weak equivalences. Hence if $\theta^{\star}$ is left Quillen, then it carries the map $\Delta^n \xrightarrow{\sim} \Delta^0$ to an equivalence $\theta^{\star}\Delta^n \xrightarrow{\sim} \theta^{\star}\Delta^0 \cong \Delta^0$, and, conversely, if $\theta^{op}\colon N\Delta^{op} \longrightarrow N\Delta^{op}$ is cofinal, then for any weak equivalence $X \xrightarrow{\sim} Y$, the induced map $\theta^{\star}X \longrightarrow \theta^{\star}Y$ factors as

$$\begin{aligned} \theta^{\star}X \simeq \operatorname{hocolim}_n X_{\theta(n)} &\simeq \operatorname{hocolim}_n P_N \\ &\simeq X \\ &\xrightarrow{\sim} Y \\ &\simeq \operatorname{hocolim}_n Y_n \\ &\simeq \operatorname{hocolim}_n Y_{\theta(n)} \simeq \theta^{\star}Y, \end{aligned}$$

which is a weak equivalence. This proves the equivalence of the third condition with the first two. □

2.2. One may call any functor $\theta\colon \Delta \longrightarrow \Delta$ satisfying the equivalent conditions above a ***combinatorial subdivision***. Work of Katerina Velcheva shows that in fact combinatorial subdivisions can be classified: they are all iterated joins of id and op. The example in which we are interested, the join $op \star \mathrm{id}$, is originally due to Segal.

2.3. **Notation.** Denote by $\epsilon\colon \Delta \longrightarrow \Delta$ the combinatorial subdivision

$$[\mathbf{n}] \longmapsto [\mathbf{n}]^{op} \star [\mathbf{n}] \cong [\mathbf{2n+1}].$$

Including $[\mathbf{n}]$ into either factor of the join $[\mathbf{n}]^{op} \star [\mathbf{n}]$ (either contravariantly or covariantly) defines two natural transformations $op \longrightarrow \epsilon$ and $\mathrm{id} \longrightarrow \epsilon$. Precomposition with ϵ induces an endofunctor $\epsilon^{\star}$ on the ordinary category of simplicial sets, together with natural transformations $\epsilon^{\star} \longrightarrow op$ and $\epsilon^{\star} \longrightarrow \mathrm{id}$.

For any simplicial set X, the ***edgewise subdivision*** of X is the simplicial set

$$\widetilde{\mathscr{O}}(X) := \epsilon^{\star} X.$$

That is, $\widetilde{\mathscr{O}}(X)$ is given by the formula

$$\widetilde{\mathscr{O}}(X)_n = \mathrm{Mor}(\Delta^{n,op} \star \Delta^n, X) \cong X_{2n+1}.$$

The two natural transformations described above give rise to a morphism

$$\widetilde{\mathscr{O}}(X) \longrightarrow X^{op} \times X,$$

functorial in X.

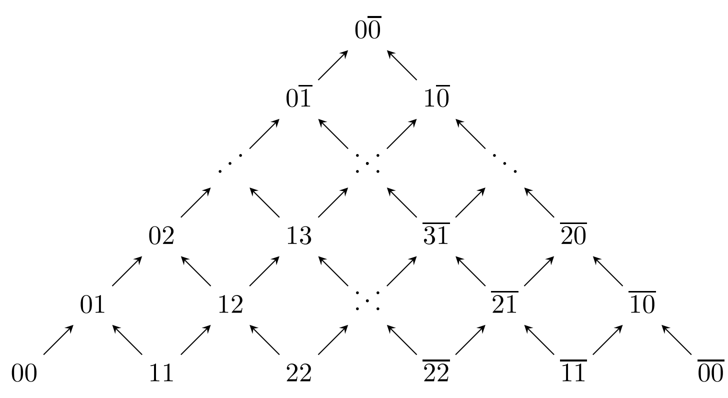
2.4. For any simplicial set X, the vertices of $\widetilde{\mathscr{O}}(X)$ are edges of X; an edge of $\widetilde{\mathscr{O}}(X)$ from $u \longrightarrow v$ to $x \longrightarrow y$ can be viewed as a commutative diagram (up to chosen homotopy)

$$\begin{array}{ccc} u & \longleftarrow & x \\ \downarrow & & \downarrow \\ v & \longrightarrow & y \end{array}$$

When X is the nerve of an ordinary category C, $\widetilde{\mathscr{O}}(X)$ is isomorphic to the nerve of the twisted arrow category of C in the sense of [8]. When X is an ∞-category, we are therefore inclined to call $\widetilde{\mathscr{O}}(X)$ the ***twisted arrow ∞-category*** of X. This terminology is justified by the following.

2.5. **Proposition** (Lurie, [29, Pr. 4.2.3])**.** *If X is an ∞-category, then the functor $\widetilde{\mathscr{O}}(X) \longrightarrow X^{op} \times X$ is a left fibration; in particular, $\widetilde{\mathscr{O}}(X)$ is an ∞-category.*

2.6. **Example.** To illustrate, for any object $\mathbf{p} \in \Delta$, the ∞-category $\widetilde{\mathscr{O}}(\Delta^p)$ is the nerve of the category



(Here we write $\overline{n}$ for $p - n$.)

3. The effective Burnside ∞-category

We now employ the edgewise subdivision to define a quasicategorical variant of the Burnside category. The essence of the idea was explored in our work on the ∞-categorical Q construction.

3.1. **Notation.** For any ∞-category C, denote by $\mathbf{R}_*(C)\colon \Delta^{op} \longrightarrow s\mathbf{Set}$ the functor given by the assignment

$$[\mathbf{n}] \longmapsto \iota\,\mathrm{Fun}(\widetilde{\mathscr{O}}(\Delta^n)^{op}, C).$$

3.2. **Proposition.** *The functor $\mathbf{R}_*\colon \mathbf{Cat}_\infty^0 \longrightarrow \mathrm{Fun}(\Delta^{op}, s\mathbf{Set})$ carries every quasicategory to a Reedy fibrant simplicial space, and it preserves weak equivalences.*

Proof. We first show that for any ∞-category C, the simplicial space $\mathbf{R}_*(C)$ is Reedy fibrant. This is the condition that for any monomorphism $K \hookrightarrow L$, the map

$$\iota\,\mathrm{Fun}(\widetilde{\mathscr{O}}(L)^{op}, C) \longrightarrow \iota\,\mathrm{Fun}(\widetilde{\mathscr{O}}(K)^{op}, C)$$

is a Kan fibration of simplicial sets. This follows immediately from Pr. 2.1 and [25, Lm. 3.1.3.6]. To see that $\mathbf{R}_*$ preserves weak equivalences, we note that since $\mathrm{Fun}(\widetilde{\mathscr{O}}(\Delta^n)^{op}, -)$ preserves weak equivalences, so does $\mathbf{R}_n$. □

3.3. **Definition.** Suppose C an ∞-category. For any integer $n \geq 0$, let us say that a functor $X\colon \widetilde{\mathscr{O}}(\Delta^n)^{op} \longrightarrow C$ is ***cartesian*** if, for any integers $0 \leq i \leq k \leq \ell \leq j \leq n$, the square

$$\begin{array}{ccc} X_{ij} & \longrightarrow & X_{kj} \\ \downarrow & & \downarrow \\ X_{i\ell} & \longrightarrow & X_{k\ell} \end{array}$$

is a pullback.

Write $\mathbf{A}_*^{\mathit{eff}}(C) \subset \mathbf{R}_*(C)$ for the subfunctor in which $\mathbf{A}_n^{\mathit{eff}}(C)$ is the full simplicial subset of $\mathbf{R}_n(C)$ spanned by the cartesian functors

$$X\colon \widetilde{\mathscr{O}}(\Delta^n)^{op} \longrightarrow C.$$

Note that since any functor that is equivalent to an cartesian functor is itself cartesian, the simplicial set $\mathbf{A}_n^{\mathit{eff}}(C)$ is a union of connected components of $\mathbf{R}_n(C)$.

3.4. **Proposition.** *For any ∞-category C that admits all pullbacks, the simplicial space $\mathbf{A}_*^{\mathit{eff}}(C)$ is a complete Segal space.*

Proof. The Reedy fibrancy of $\mathbf{A}_*^{\mathit{eff}}(C)$ follows easily from the Reedy fibrancy of $\mathbf{R}_*(C)$.

To see that $\mathbf{A}_*^{\mathit{eff}}(C)$ is a Segal space, it is necessary to show that for any integer $n \geq 1$, the Segal map

$$\mathbf{A}_n^{\mathit{eff}}(C) \longrightarrow \mathbf{A}_1^{\mathit{eff}}(C) \times_{\mathbf{A}_0^{\mathit{eff}}(C)} \cdots \times_{\mathbf{A}_0^{\mathit{eff}}(C)} \mathbf{A}_1^{\mathit{eff}}(C)$$

is an equivalence. Let L_n denote the ordinary category

$$00 \longleftarrow 01 \longrightarrow 11 \longleftarrow 12 \longrightarrow \cdots (n-1)(n-1) \longleftarrow (n-1)n \longrightarrow nn.$$

The target of the Segal map can then be identified with the maximal Kan complex contained in the ∞-category

$$\mathrm{Fun}(NL_n, C).$$

The Segal map is therefore an equivalence by the uniqueness of limits in ∞-categories [25, Pr. 1.2.12.9].

Finally, to check that $\mathbf{A}_*^{eff}(C)$ is complete, let E be the nerve of the contractible ordinary groupoid with two objects; then completeness is equivalent to the assertion that the Rezk map

$$\mathbf{A}_0^{eff}(C) \longrightarrow \lim_{[\mathbf{n}]\in(\Delta/E)^{op}} \mathbf{A}_n^{eff}(C)$$

is a weak equivalence. The source of this map can be identified with ιC; its target can be identified with the full simplicial subset of

$$\iota \operatorname{Fun}(\widetilde{\mathscr{O}}(E)^{op}, C)$$

spanned by those functors $X\colon \widetilde{\mathscr{O}}(E)^{op} \longrightarrow C$ such that for any simplex $\Delta^n \longrightarrow E$, the induced functor $\widetilde{\mathscr{O}}(\Delta^n)^{op} \longrightarrow C$ is ambigressive. Note that the twisted arrow category of the contractible ordinary groupoid with two objects is the contractible ordinary groupoid with four objects. Consequently, the image of any functor $X\colon \widetilde{\mathscr{O}}(E)^{op} \longrightarrow C$ is contained in ιC. Thus the target of the Rezk map can be identified with $\iota \operatorname{Fun}(\widetilde{\mathscr{O}}(E)^{op}, C)$ itself, and the Rezk map is an equivalence. □

3.5. It is now clear that $\mathbf{A}_*^{eff}$ defines a functor of ∞-categories

$$\mathbf{A}_*^{eff}\colon \mathbf{Cat}_\infty^{\mathrm{lex}} \longrightarrow \mathbf{CSS},$$

where $\mathbf{Cat}_\infty^{\mathrm{lex}} \subset \mathbf{Cat}_\infty$ is the subcategory consisting of ∞-categories with all finite limits and left exact functors between them, and where $\mathbf{CSS} \subset \operatorname{Fun}(\Delta^{op}, \mathbf{Kan})$ is the full subcategory spanned by complete Segal spaces.

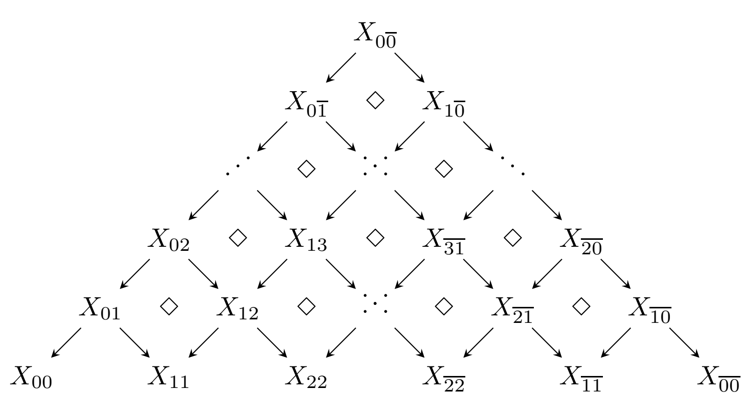
Joyal and Tierney show that the functor that carries a simplicial space $\mathbf{X}$ to the simplicial set whose n-simplices are the vertices of $\mathbf{X}_n$ induces an equivalence of ∞-categories $\mathbf{CSS} \longrightarrow \mathbf{Cat}_\infty$. This leads us to the following definition.

3.6. **Definition.** For any ∞-category C that admits all pullbacks, denote by $A^{eff}(C)$ the ∞-category whose n-simplices are vertices of $\mathbf{A}_n^{eff}(C)$, i.e., cartesian functors $\widetilde{\mathscr{O}}(\Delta^n)^{op} \longrightarrow C$. We may call this the ***effective Burnside*** ∞***-category of*** C.

This defines a functor of ∞-categories

$$A^{eff}\colon \mathbf{Cat}_\infty^{\mathrm{lex}} \longrightarrow \mathbf{Cat}_\infty.$$

3.7. For any ∞-category C that admits all pullbacks, an n-simplex of $A^{eff}(C)$ is a diagram



of C in which every square is a pullback. Here we write $\overline{n}$ for $p-n$.

Another way of describing $A^{\mathit{eff}}(C)$ is as follows. The objects of $A^{\mathit{eff}}(C)$ are precisely those of C. Between objects X and Y, the space of maps is given by

$$\mathrm{Map}_{A^{\mathit{eff}}(C)}(X,Y) \simeq \iota C_{/\{X,Y\}},$$

where $\{X,Y\}$ denotes the diagram $\{x,y\} \longrightarrow C$ from the discrete simplicial set $\{x,y\}$ to C that carries x to X and y to Y. Composition

$$\iota C_{/\{X,Y\}} \times \iota C_{/\{Y,Z\}} \longrightarrow \iota C_{/\{X,Z\}}$$

is defined, up to coherent homotopy, by pullback $- \times_Y -$.

3.8**.** Note that the traditional Burnside category is distinct from $A^{\mathit{eff}}(C)$ in two ways. First, when forming the traditional Burnside category, one begins by studying *isomorphism classes* of spans between objects. This is to ensure that one obtains a nice set of maps for which the pullback construction is sensible. In our effective Burnside ∞-category, we do not pass to isomorphism classes. Rather, we are content to take the entire *space* of spans between objects as our mapping space. We again use pullback to define composition, and we lose no sleep over the fact that pullbacks are only defined up to coherent equivalence, since composition in any ∞-category is only required to be defined up to coherent equivalence in the first place. The ***ordinary effective Burnside category*** of an ordinary category C may be identified with the homotopy category $hA^{\mathit{eff}}(NC)$ of $A^{\mathit{eff}}(NC)$.

Second, the ordinary Burnside category is usually defined as the "local group completion" of this ordinary effective Burnside category. Then Mackey functors are then defined as additive functors from this Burnside category to, say, the category of abelian groups. This is overkill: if the target is already group complete, one knows already what additive functors from the Burnside category will be in terms of the category before group completion. The group completion is a relatively minor procedure for ordinary categories, but for ∞-categories, group completion is serious business. Indeed, if $\mathbf{F}$ is the ordinary category of finite sets, then when one forms the local group completion $A(N\mathbf{F})$ of $A^{\mathit{eff}}(N\mathbf{F})$, the space of endomorphisms on the one point set becomes

$$\mathrm{Map}_{A(N\mathbf{F})}(*,*) \simeq QS^0,$$

by Barratt–Priddy–Quillen. To avoid such complications, we happily stick with the effective Burnside ∞-category.

3.9. **Notation.** The two natural transformations $\varepsilon^\star \longrightarrow \mathit{op}$ and $\varepsilon^\star \longrightarrow \mathrm{id}$ induce two natural transformations

$$(\cdot)_\star \colon \mathrm{id} \longrightarrow A^{\mathit{eff}} \quad \text{and} \quad (\cdot)^\star \colon \mathit{op} \longrightarrow A^{\mathit{eff}}.$$

For any morphism $f \colon U \longrightarrow V$ of an ∞-category C that admits all pullbacks, one thus obtains morphisms

$$f_\star \colon U \longrightarrow V \quad \text{and} \quad f^\star \colon V \longrightarrow U.$$

For any pullback square

$$\begin{array}{ccc} U & \xrightarrow{i} & X \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle g} \\ V & \xrightarrow[j]{} & Y, \end{array}$$

one obtains a homotopy

$$g^{\star} \circ j_{\star} \simeq i_{\star} \circ f^{\star} \colon V \longrightarrow X.$$

3.10. **Notation.** Additionally, there is a self-duality equivalence

$$\widetilde{\mathscr{O}}^{op} \xrightarrow{\sim} \widetilde{\mathscr{O}},$$

whence we have a natural equivalence

$$D \colon A^{\mathit{eff},op} \xrightarrow{\sim} A^{\mathit{eff}}$$

such that the diagram

$$\begin{array}{ccccc} & & A^{\mathit{eff},op} & & \\ & \overset{(\cdot)^{\star,op}}{\nearrow} & & \overset{(\cdot)_{\star}^{op}}{\nwarrow} & \\ \mathrm{id} & & \downarrow D & & op \\ & \underset{(\cdot)_{\star}}{\searrow} & & \underset{(\cdot)^{\star}}{\swarrow} & \\ & & A^{\mathit{eff}} & & \end{array}$$

commutes.

4. Disjunctive ∞-categories

An ∞-category with all finite limits is disjunctive if the coproduct acts effectively as a disjoint union. The effective Burnside ∞-category $A^{\mathit{eff}}(C)$ of a disjunctive ∞-category C has the peculiar property that the initial object of C becomes a zero object in $A^{\mathit{eff}}(C)$, and the coproduct in C becomes both the coproduct and the product in $A^{\mathit{eff}}(C)$. This permits us to regard the effective Burnside ∞-category as somewhat "algebraic" in nature.

4.1. **Definition.** Suppose C is an ∞-category. Then C is said to ***admit direct sums*** if the following conditions hold.

(4.1.1) The ∞-category C is pointed.
(4.1.2) The ∞-category C has all finite products and coproducts.
(4.1.3) For any finite set I and any I-tuple $(X_i)_{i \in I}$ of objects of C, the map

$$\coprod X_I \longrightarrow \prod X_I$$

in hC — given by the maps $\phi_{ij} \colon X_i \longrightarrow X_j$, where ϕ_{ij} is zero unless $i = j$, in which case it is the identity — is an isomorphism.

If C admits finite direct sums, then for any finite set I and any I-tuple $(X_i)_{i \in I}$ of objects of C, we denote by $\bigoplus X_I$ the product (or, equivalently, the coproduct) of the X_i.

If C admits direct sums, then C will be said to be ***additive*** if its homotopy category hC is additive. Denote by $\mathbf{Cat}_{\infty}^{add} \subset \mathbf{Cat}_{\infty}(\kappa_1)$ the subcategory consisting of locally small additive ∞-categories and functors between them that preserve direct sums.

We are mostly interested in ∞-categories C such that the ∞-category $A^{\mathit{eff}}(C)$ admit direct sums. To ensure this, we introduce the following class of ∞-categories.

4.2. **Definition.** An ∞-category will be called ***disjunctive*** if it admits all finite limits and finite coproducts and if, in addition, finite coproducts are disjoint and universal [25, §6.1.1, (ii) and (iii)].

Equivalently, an ∞-category C that admits all finite limits and all finite coproducts is disjunctive just in case, for any finite set I and any collection $\{X_i\}_{i\in I}$ of objects of C, the natural functor

$$\prod_{i\in I} C_{/X_i} \longrightarrow C_{/\coprod_{i\in I} X_i}$$

given by the coproduct is an equivalence of ∞-categories. Its inverse is given informally by the assignment

$$U \longmapsto (U \times_{\coprod_{j\in I} X_j} X_i)_{i\in I}$$

Let us denote by $\mathbf{Cat}_\infty^{disj} \subset \mathbf{Cat}_\infty$ the subcategory whose objects are (small) disjunctive ∞-categories and whose morphisms are those functors that preserve pullbacks and finite coproducts.

In ordinary category theory, it may be more customary to refer to categories with the properties described above with the portmanteau "lextensive." We won't be doing that.

4.3. **Proposition.** *If C is a disjunctive ∞-category, then the ∞-category $A^{eff}(C)$ admits direct sums.*

Proof. We show that the natural functor $(\cdot)_\star \colon C \longrightarrow A^{eff}(C)$ preserves coproducts. The result will then follow from the self-duality $D\colon A^{eff}(C)^{op} \simeq A^{eff}(C)$. Unwinding the definitions, the claim that $(\cdot)_\star$ preserves coproducts amounts to the following claim: for any object Y of C, the space

$$\iota C_{/\{\varnothing,Y\}}$$

is contractible (which follows directly from [25, Lm. 6.1.3.6]), and for any objects X and X' of C, the map

$$\iota C_{/\{X\sqcup Y,Z\}} \longrightarrow \iota C_{/\{X,Z\}} \times \iota C_{/\{Y,Z\}}$$

given informally by the assignment

$$W \longmapsto (W \times_{X\sqcup Y} X, W \times_{X\sqcup Y} Y)$$

is an equivalence. We claim that the map

$$\iota C_{/\{X,Z\}} \times \iota C_{/\{Y,Z\}} \longrightarrow \iota C_{/\{X\sqcup Y,Z\}}$$

given informally by the assignment

$$(U,V) \longmapsto U \sqcup V$$

is a homotopy inverse. Indeed, the statement that

$$W \simeq (W \times_{X\sqcup Y} X) \sqcup (W \times_{X\sqcup Y} Y)$$

follows from the universality of finite coproducts, and the statement that

$$U \simeq (U \sqcup V) \times_{X\sqcup Y} X \quad \text{and} \quad V \simeq (U \sqcup V) \times_{X\sqcup Y} Y$$

follows from the identifications

$$X \simeq X \times_{X\sqcup Y} X, \qquad \varnothing \simeq X \times_{X\sqcup Y} Y \quad \text{and} \quad Y \simeq Y \times_{X\sqcup Y} Y,$$

all of which follow easily from the disjointness and universality of coproducts. □

Note that we do not quite use the full strength of disjunctivity here. It would have been enough to assume only that C admits pullbacks and finite coproducts and that finite coproducts are disjoint and universal. However, we will use the further condition that C admits a terminal object and hence all finite products when we study the Burnside Mackey functor.

5. Disjunctive triples

In a little while we will define Mackey functors on a disjunctive ∞-category C (valued in spectra, say) as direct-sum preserving functors M from the effective Burnside category $A^{eff}(C)$. This means that for any object X of C, we'll have an associated spectrum $M(X)$, and for any morphism $X \longrightarrow Y$ of C, we'll have both a morphism $M(X) \longrightarrow M(Y)$ and a morphism $M(Y) \longrightarrow M(X)$. So a Mackey functor will splice together a covariant functor and a contravariant functor.

However, it is not always reasonable to expect both covariance and contravariance for all morphisms simultaneously. Rather, one may wish instead to specify classes of morphisms in which one has covariance and contravariance. This leads to the notion of a disjunctive triple.

5.1. Recall [2, Df. 1.11] that a ***pair*** of ∞-categories $(C, C_\dagger)$ consists of an ∞-category C and a subcategory $C_\dagger$ [25, §1.2.11] that contains all the equivalences.

A ***triple*** of ∞-categories is an ∞-category equipped with two pair structures. That is, a triple $(C, C_\dagger, C^\dagger)$ consists of an ∞-category C and two subcategories

$$C_\dagger, C^\dagger \subset C,$$

each of which contains all the equivalences. We call morphisms of $C_\dagger$ ***ingressive*** and morphisms of $C^\dagger$ ***egressive***.

5.2. **Definition.** A triple $(C, C_\dagger, C^\dagger)$ of ∞-categories is said to be ***adequate*** if the following conditions obtain.

(5.2.1) For any ingressive morphism $Y \rightarrowtail X$ and any egressive morphism $X' \twoheadrightarrow X$, there exists a pullback square

$$\begin{array}{ccc} Y' & \longrightarrow & X' \\ \downarrow & & \downarrow \\ Y & \rightarrowtail & X. \end{array}$$

(5.2.2) In any pullback square

$$\begin{array}{ccc} Y' & \xrightarrow{f'} & X' \\ \downarrow & & \downarrow \\ Y & \xrightarrow[f]{} & X. \end{array}$$

if f is ingressive (respectively, egressive), then so is f'.

We will say that an adequate triple $(C, C_\dagger, C^\dagger)$ is a ***disjunctive triple*** if the following further conditions obtain.

(5.2.3) The ∞-category C admits finite coproducts.

(5.2.4) The class of ingressive morphisms and the class of egressive morphisms are each ***compatible with coproducts*** in the following sense. First, any morphism from an initial object is both ingressive and egressive. Second, for any objects $X, Y, Z \in C$, a morphism $X \sqcup Y \longrightarrow Z$ is ingressive (respectively, egressive) just in case both the restrictions $X \longrightarrow Z$ and $Y \longrightarrow Z$ are so.

(5.2.5) Suppose I and J finite sets. Suppose that for any pair $(i, j) \in I \times J$, we are given a pullback square

$$\begin{array}{ccc} X'_{ij} & \rightarrowtail & Y'_j \\ \downarrow & & \downarrow \\ X_i & \rightarrowtail & Y \end{array}$$

a pullback square in which $X_i \rightarrowtail Y$ is ingressive and $Y'_j \twoheadrightarrow Y$ is egressive. Then the resulting square

$$\begin{array}{ccc} \coprod_{(i,j)\in I\times J} X'_{ij} & \rightarrowtail & \coprod_{j\in J} Y'_j \\ \downarrow & & \downarrow \\ \coprod_{i\in I} X_i & \rightarrowtail & Y \end{array}$$

is also a pullback square.

If $(C, C_\dagger, C^\dagger)$ is a disjunctive triple, then we shall call a pullback square

$$\begin{array}{ccc} Y' & \overset{j}{\rightarrowtail} & Y \\ {\scriptstyle p'}\downarrow & & \downarrow{\scriptstyle p} \\ X' & \underset{i}{\rightarrowtail} & X \end{array}$$

of C ***disjunctive*** if i (and hence also j) is ingressive and p (and hence also p') is egressive.

Now a ***functor of disjunctive triples*** is a functor of triples

$$f\colon (C, C_\dagger, C^\dagger) \longrightarrow (D, D_\dagger, D^\dagger)$$

(i.e., a functor $C \longrightarrow D$ that carries ingressive morphisms to ingressive morphisms and egressive morphisms to egressive morphisms) such that f preserves finite coproducts and ambigressive pullbacks.

5.3. **Notation.** Let us write $\mathbf{Trip}_\infty^{disj}$ for the subcategory of the ∞-category $\mathbf{Trip}_\infty$ of small triples of ∞-categories whose objects are disjunctive triples and whose morphisms are functors of disjunctive triples.

5.4. **Example.** Of course every disjunctive ∞-category C admits its ***maximal triple structure*** (C, C, C). Hence anything said of disjunctive triples specializes to disjunctive ∞-categories.

5.5. **Definition.** Suppose $(C, C_\dagger, C^\dagger)$ a triple of ∞-categories. For any integer $n \geq 0$, let us say that a functor $X\colon \widetilde{\mathscr{O}}(\Delta^n)^{op} \longrightarrow C$ is ***ambigressive cartesian*** (relative to the triple structure) if, for any integers $0 \leq i \leq k \leq \ell \leq j \leq n$, the square

$$\begin{array}{ccc} X_{ij} & \twoheadrightarrow & X_{kj} \\ \downarrow & & \downarrow \\ X_{i\ell} & \rightarrowtail & X_{k\ell} \end{array}$$

is a pullback in which the morphisms $X_{ij} \rightarrowtail X_{kj}$ and $X_{i\ell} \rightarrowtail X_{k\ell}$ are ingressive, and the morphisms $X_{ij} \twoheadrightarrow X_{i\ell}$ and $X_{kj} \twoheadrightarrow X_{k\ell}$ are egressive.

Recall the functor $\mathbf{R}_*(C)\colon \Delta^{op} \longrightarrow \mathbf{Kan}$ from Nt. 3.1. Write $\mathbf{A}^{\mathit{eff}}_*(C, C_\dagger, C^\dagger) \subset \mathbf{R}_*(C)$ for the subfunctor in which $\mathbf{A}^{\mathit{eff}}_n(C, C_\dagger, C^\dagger)$ is the full simplicial subset of $\mathbf{R}_n(C)$ spanned by the cartesian functors $X\colon \widetilde{\mathscr{O}}(\Delta^n)^{op} \longrightarrow C$. Note that since any functor that is equivalent to an cartesian functor is itself cartesian, the simplicial set $\mathbf{A}^{\mathit{eff}}_n(C, C_\dagger, C^\dagger)$ is a union of connected components of $\mathbf{R}_n(C)$.

The proof of the following is virtually identical to that of Pr. 3.4.

5.6. **Proposition.** *For any adequate triple of ∞-categories $(C, C_\dagger, C^\dagger)$, the simplicial space $\mathbf{A}^{\mathit{eff}}_*(C, C_\dagger, C^\dagger)$ is a complete Segal space.*

5.7. **Definition.** For any adequate triple of ∞-categories $(C, C_\dagger, C^\dagger)$, denote by $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)$ the ∞-category whose n-simplices are vertices of $\mathbf{A}^{\mathit{eff}}_n(C, C_\dagger, C^\dagger)$, i.e., ambigressive cartesian functors $\widetilde{\mathscr{O}}(\Delta^n)^{op} \longrightarrow C$. We may call this the ***effective Burnside ∞-category of*** $(C, C_\dagger, C^\dagger)$.

5.8**.** Suppose $(C, C_\dagger, C^\dagger)$ a locally small adequate triple of ∞-categories $(C, C_\dagger, C^\dagger)$. Here's an alternate way to go about defining $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)$. Write $\mathscr{P}(C) := \mathrm{Fun}(C^{op}, \mathbf{Kan})$ for the usual ∞-category of presheaves of spaces. We may describe (an equivalent version of)

$$A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \subset A^{\mathit{eff}}(\mathscr{P}(C))$$

as the subcategory whose objects are those functors that are representable, in which a morphism $F \longrightarrow G$ of $A^{\mathit{eff}}(\mathscr{P}(C))$ exhibited as a diagram

$$\begin{array}{ccccc} & & H & & \\ & \swarrow & & \searrow & \\ F & & & & G, \end{array}$$

lies in $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)$ just in case the morphism of C representing the morphism $H \longrightarrow F$ of $\mathscr{P}(C)$ is egressive and the morphism of C representing the morphism $H \longrightarrow G$ of $\mathscr{P}(C)$ is ingressive. Since the pullback of an ingressive (respectively, egressive) morphism along an egressive (resp., ingressive) morphism is ingressive (resp., egressive) of C, and since the Yoneda embedding preserves all limits that exist in C, it follows that $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)$ is indeed a subcategory.

Note that for any disjunctive triple $(C, C_\dagger, C^\dagger)$, the subcategory

$$A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \subset A^{\mathit{eff}}(\mathscr{P}(C))$$

is closed under direct sums.

5.9. **Notation.** Suppose $(C, C_\dagger, C^\dagger)$ an adequate triple. The two natural transformations

$$(\cdot)_\star\colon \mathrm{id} \longrightarrow A^{\mathit{eff}} \quad \text{and} \quad (\cdot)^\star\colon \mathit{op} \longrightarrow A^{\mathit{eff}}$$

restrict to yield functors

$$(\cdot)_\star\colon C_\dagger \longrightarrow A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \quad \text{and} \quad (\cdot)^\star\colon C^{\dagger,op} \longrightarrow A^{\mathit{eff}}(C, C_\dagger, C^\dagger)$$

Consequently, for any ingressive morphism $f\colon U \rightarrowtail V$ of C, one obtains a morphism $f_\star\colon U \longrightarrow V$, and for any egressive morphism $f\colon U \twoheadrightarrow V$ of C, one obtains a morphism $f^\star\colon V \longrightarrow U$. Additionally, for any pullback square

$$\begin{array}{ccc} U & \overset{i}{\rightarrowtail} & X \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle g} \\ V & \underset{j}{\rightarrowtail} & Y \end{array}$$

in which i, j are ingressive and f, g are egressive, one obtains a homotopy

$$g^\star \circ j_\star \simeq i_\star \circ f^\star\colon V \longrightarrow X.$$

5.10. **Notation.** Suppose $(C, C_\dagger, C^\dagger)$ a disjunctive triple. Then the self-duality equivalence

$$\widetilde{\mathscr{O}}^{op} \xrightarrow{\sim} \widetilde{\mathscr{O}},$$

induces the natural equivalence

$$D\colon A^{\mathit{eff}}(C, C^\dagger, C_\dagger)^{op} \xrightarrow{\sim} A^{\mathit{eff}}(C, C_\dagger, C^\dagger)$$

such that the diagram

$$\begin{array}{ccccc} & & A^{\mathit{eff}}(C, C^\dagger, C_\dagger)^{op} & & \\ & \nearrow^{(\cdot)^{\star,op}} & & \nwarrow^{(\cdot)_\star^{op}} & \\ C_\dagger & & \downarrow{\scriptstyle D} & & C^{\dagger,op} \\ & \searrow_{(\cdot)_\star} & & \swarrow_{(\cdot)^\star} & \\ & & A^{\mathit{eff}}(C, C_\dagger, C^\dagger) & & \end{array}$$

commutes.

5.11. A functor of disjunctive triples $f\colon (C, C_\dagger, C^\dagger) \longrightarrow (D, D_\dagger, D^\dagger)$ induces a functor $A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \longrightarrow A^{\mathit{eff}}(D, D_\dagger, D^\dagger)$ that preserves direct sums.

6. Mackey functors

6.1. **Definition.** Suppose E an additive ∞-category, and suppose $(C, C_\dagger, C^\dagger)$ a disjunctive triple. Then a ***Mackey functor on*** $(C, C_\dagger, C^\dagger)$ valued in E is a functor

$$M\colon A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \longrightarrow E$$

that preserves direct sums. If C itself is a disjunctive ∞-category, then a ***Mackey functor on*** C is nothing more than a Mackey functor on the maximal triple (C, C, C).

6.2. **Example.** When E is the nerve of an ordinary additive category, a Mackey functor $M\colon A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \longrightarrow E$ factors in an essentially unique fashion through the homotopy category $hA^{\mathit{eff}}(C, C_\dagger, C^\dagger)$ and then its local group completion (obtained by taking the Grothendieck group of the Hom sets). Hence the notion of Mackey functor described here subsumes the one defined by Dress [4].

Note that some authors define "ordinary" Mackey functors as functors on the local group completion of the *opposite* category $hA^{\mathit{eff}}(C, C_\dagger, C^\dagger)^{op}$. This is just a matter of convention, as the duality functor provides the equivalence $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^{op} \simeq A^{\mathit{eff}}(C, C^\dagger, C_\dagger)$.

6.3. **Notation.** Suppose E an additive ∞-category, and suppose $(C, C_\dagger, C^\dagger)$ a small disjunctive triple. Then we denote by

$$\mathbf{Mack}(C, C_\dagger, C^\dagger; E) \subset \mathrm{Fun}(A^{\mathit{eff}}(C, C_\dagger, C^\dagger), E)$$

the full subcategory spanned by the Mackey functors. This is covariantly functorial for additive functors in E. For any functor $f\colon (C, C_\dagger, C^\dagger) \longrightarrow (D, D_\dagger, D^\dagger)$ of disjunctive triples, we have an induced functor

$$f^\star\colon \mathbf{Mack}(D, D_\dagger, D^\dagger, E) \longrightarrow \mathbf{Mack}(C, C_\dagger, C^\dagger, E).$$

These functors fit together to yield a functor

$$\mathbf{Mack}\colon \mathbf{Trip}_\infty^{disj,op} \times \mathbf{Cat}_\infty^{add} \longrightarrow \mathbf{Cat}_\infty(\kappa_1).$$

If C is a disjunctive ∞-category, then $\mathbf{Mack}(C, E) = \mathbf{Mack}(C, C, C; E)$.

In fact, let's see that the functor **Mack** is valued in $\mathbf{Cat}_\infty^{add}$.

6.4. **Proposition.** *For any disjunctive triple $(C, C_\dagger, C^\dagger)$ and for any additive ∞-category E, the ∞-category $\mathbf{Mack}(C, C_\dagger, C^\dagger; E)$ is additive.*

Proof. It is easy to see that $\mathrm{Fun}(A^{\mathit{eff}}(C, C_\dagger, C^\dagger), E)$ is additive. The full subcategory

$$\mathbf{Mack}(C, C_\dagger, C^\dagger; E) \subset \mathrm{Fun}(A^{\mathit{eff}}(C, C_\dagger, C^\dagger), E)$$

is closed under finite direct sums by noting that the constant functor at a zero object clearly preserves direct sums, and for any Mackey functors M and N, the functor $M \oplus N$ carries zero objects to zero objects, and

$$\begin{aligned}(M \oplus N)(X \oplus Y) &= M(X \oplus Y) \oplus N(X \oplus Y)\\ &\simeq M(X) \oplus M(Y) \oplus N(X) \oplus N(Y)\\ &\simeq (M \oplus N)(X) \oplus (M \oplus N)(Y)\end{aligned}$$

for any objects $X, Y \in A^{\mathit{eff}}(C, C_\dagger, C^\dagger)$. □

Perhaps surprisingly, Mackey functors are closed under all limits and colimits.

6.5. **Proposition.** *For any disjunctive triple $(C, C_\dagger, C^\dagger)$ and for any additive ∞-category E that admits all limits (respectively, all colimits), the full subcategory $\mathbf{Mack}(C, C_\dagger, C^\dagger; E) \subset \mathrm{Fun}(A^{\mathit{eff}}(C, C_\dagger, C^\dagger), E)$ is closed under limits (resp., under colimits).*

Proof. We will prove the statement about colimits. The statement about limits will then follow from consideration of the equivalence

$$\mathbf{Mack}(C, C_\dagger, C^\dagger; E)^{op} \simeq \mathbf{Mack}(C, C^\dagger, C_\dagger; E^{op}).$$

We have already seen that $\mathbf{Mack}(C, C_\dagger, C^\dagger; E) \subset \mathrm{Fun}(A^{\mathit{eff}}(C, C_\dagger, C^\dagger), E)$ is closed under finite coproducts; it therefore remains to show that if Λ is a sifted ∞-category and if $M\colon \Lambda \longrightarrow \mathbf{Mack}(C, C_\dagger, C^\dagger; E)$ is a diagram of Mackey functors, then the colimit $M_\infty = \mathrm{colim}_{\alpha\in\Lambda} M_\alpha$ in $\mathrm{Fun}(A^{\mathit{eff}}(C, C_\dagger, C^\dagger), E)$ is again a Mackey functor. For this, suppose $X, Y \in A^{\mathit{eff}}(C, C_\dagger, C^\dagger)$, and observe that

$$M_\infty(X \oplus Y) \simeq \mathrm{colim}_{\alpha\in\Lambda} M_\alpha(X \oplus Y) \simeq \mathrm{colim}_{\alpha\in\Lambda} M_\alpha(X) \oplus M_\alpha(Y).$$

Now since Λ is sifted, we further have

$$\mathrm{colim}_{\alpha\in\Lambda} M_\alpha(X) \oplus M_\alpha(Y) \simeq \mathrm{colim}_{\alpha,\beta\in\Lambda} M_\alpha(X) \oplus M_\beta(Y).$$

Since

$$\mathrm{colim}_{\alpha,\beta\in\Lambda} M_\alpha(X) \oplus M_\beta(Y) \simeq \mathrm{colim}_{\alpha\in\Lambda} M_\alpha(X) \oplus \mathrm{colim}_{\beta\in\Lambda} M_\beta(Y),$$

we obtain

$$M_\infty(X \oplus Y) \simeq M_\infty(X) \oplus M_\infty(Y). \qquad \square$$

6.5.1. **Corollary.** *For any disjunctive triple $(C, C_\dagger, C^\dagger)$ and for any additive ∞-category E that admits all limits (respectively, all colimits), limits (resp., colimits) in $\mathbf{Mack}(C, C_\dagger, C^\dagger; E)$ are computed objectwise.*

6.6. **Example.** For any disjunctive triple $(C, C_\dagger, C^\dagger)$, the effective Burnside ∞-category admits a local group completion, which is a universal target for Mackey functors. This is the ***Burnside ∞-category***. More precisely, there exists an additive category $A(C, C_\dagger, C^\dagger)$ and a Mackey functor

$$A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \longrightarrow A(C, C_\dagger, C^\dagger)$$

with the following universal property. For any additive ∞-category E, the functor

$$\mathrm{Fun}^{add}(A(C, C_\dagger, C^\dagger), E) \longrightarrow \mathbf{Mack}(C, C_\dagger, C^\dagger; E)$$

is an equivalence, where $\mathrm{Fun}^{add}(A(C, C_\dagger, C^\dagger), E) \subset \mathrm{Fun}(A(C, C_\dagger, C^\dagger), E)$ is the full subcategory of additive functors.

This follows from the fact that the functor

$$\mathbf{Mack}(C, C_\dagger, C^\dagger; -)\colon \mathbf{Cat}_\infty^{add} \longrightarrow \mathbf{Cat}_\infty^{add}$$

preserves all limits, which in turn follows from the fact that limits in $\mathbf{Cat}_\infty^{add}$ are computed in the ∞-category $\mathbf{Cat}_\infty$. We leave the details to the reader, as we will not need the Burnside ∞-category itself in this paper.

Mackey functors valued in an additive ∞-category E will inherit duality functors. To illustrate, we focus particularly on the case of Mackey functors valued in finite spectra.

6.7. Suppose $(C, C_\dagger, C^\dagger)$ a disjunctive triple. Then the equivalence

$$D\colon A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \xrightarrow{\sim} A^{\mathit{eff}}(C, C^\dagger, C_\dagger)^{op}$$

induces an equivalence

$$\mathbf{Mack}(C, C_\dagger, C^\dagger; E) \simeq \mathbf{Mack}(C, C^\dagger, C_\dagger; E^{op})^{op}$$

for any additive ∞-category E.

6.8. **Definition.** Suppose $(C, C_\dagger, C^\dagger)$ a disjunctive triple. The (Spanier–Whitehead) duality functor $\mathbf{Sp}^\omega \xrightarrow{\sim} \mathbf{Sp}^{\omega,op}$ for finite spectra can be composed with the equivalence above to yield an equivalence

$$\mathbf{Mack}(C, C_\dagger, C^\dagger; \mathbf{Sp}^\omega)^{op} \simeq \mathbf{Mack}(C, C_\dagger, C^\dagger; \mathbf{Sp}^{\omega,op})^{op} \simeq \mathbf{Mack}(C, C^\dagger, C_\dagger; \mathbf{Sp}^\omega).$$

The image of a Mackey functor

$$M\colon A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \longrightarrow \mathbf{Sp}^\omega$$

under this equivalence is the ***dual Mackey functor***

$$M^\vee\colon A^{\mathit{eff}}(C, C^\dagger, C_\dagger) \longrightarrow \mathbf{Sp}^\omega.$$

We conclude this subsection by remarking on the potential *covariant* dependence of $\mathbf{Mack}(C, C_\dagger, C^\dagger; E)$ on C.

6.9. **Notation.** Suppose E a presentable additive ∞-category, suppose $(C, C_\dagger, C^\dagger)$ and $(D, D_\dagger, D^\dagger)$ disjunctive ∞-categories, and suppose

$$f\colon (C, C_\dagger, C^\dagger) \longrightarrow (D, D_\dagger, D^\dagger)$$

a functor of disjunctive triples. Then the induced functor

$$f^\star\colon \mathbf{Mack}(D, D_\dagger, D^\dagger; E) \longrightarrow \mathbf{Mack}(C, C_\dagger, C^\dagger; E)$$

preserves limits (since they are computed objectwise), whence it follows from the Adjoint Functor Theorem [25] that it admits a left adjoint $f_!$. These left adjoints fit together to yield a functor

$$\mathbf{Mack}\colon \mathbf{Trip}_\infty^{disj} \times \mathbf{Pr}^{\mathbf{L},add} \longrightarrow \mathbf{Pr}^{\mathbf{L},add},$$

where, in the notation of [25, Df. 5.5.3.1],

$$\mathbf{Pr}^{\mathbf{L},add} := \mathbf{Pr}^{\mathbf{L}} \cap \mathbf{Cat}_\infty^{add},$$

the ∞-category of presentable additive ∞-categories, whose morphisms are left adjoints.

7. Mackey stabilization

7.1. **Definition.** Suppose $(C, C_\dagger, C^\dagger)$ a disjunctive triple, suppose E a presentable ∞-category in which filtered colimits are left exact [25, Df. 7.3.4.2], and suppose

$$f\colon A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \longrightarrow E \quad \text{and} \quad F\colon A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \longrightarrow \mathbf{Sp}(E)$$

two functors. Then a natural transformation

$$\eta\colon f \longrightarrow \Omega^\infty \circ F$$

will be said to exhibit F as the ***Mackey stabilization*** of f if F is a Mackey functor, and if, for any Mackey functor $M\colon A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \longrightarrow \mathbf{Sp}(E)$, the map

$$\mathrm{Map}_{\mathbf{Mack}(C,C_\dagger,C^\dagger;\mathbf{Sp}(E))}(F, M) \longrightarrow \mathrm{Map}_{\mathrm{Fun}(A^{\mathit{eff}}(C,C_\dagger,C^\dagger),E)}(f, \Omega^\infty \circ M)$$

induced by η is an equivalence.

We shall now show that Mackey stabilization exist and are computable by means of a Goodwillie derivative. In particular, we will show that the functor

$$\Omega^\infty \circ -\colon \mathbf{Mack}(C, C_\dagger, C^\dagger; \mathbf{Sp}(E)) \longrightarrow \mathrm{Fun}(A^{\mathit{eff}}(C, C_\dagger, C^\dagger), E)$$

admits a left adjoint.

7.2. **Notation.** Suppose $(C, C_\dagger, C^\dagger)$ a disjunctive triple. Then we write

$$\mathrm{D}A(C, C_\dagger, C^\dagger) := \mathscr{P}_\Sigma(A^{\mathit{eff}}(C, C_\dagger, C^\dagger))$$

for the nonabelian derived ∞-category of $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)$ [25]. This ∞-category admits all colimits, and it comes equipped with a fully faithful functor

$$j\colon A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \hookrightarrow \mathrm{D}A(C, C_\dagger, C^\dagger).$$

These are uniquely characterized by *either* of the following conditions.

(7.2.1) For any ∞-category E that admits all colimits, the restriction functor
$$\mathrm{Fun}^{\mathrm{L}}(\mathrm{D}A(C, C_\dagger, C^\dagger), E) \longrightarrow \mathrm{Fun}(A^{\mathit{eff}}(C, C_\dagger, C^\dagger), E)$$
induced by j is fully faithful, and its essential image is spanned by those functors $A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \longrightarrow E$ that preserve finite coproducts.

(7.2.2) For any ∞-category E with all sifted colimits, the restriction functor
$$\mathrm{Fun}_{\mathscr{G}}(\mathrm{D}A(C, C_\dagger, C^\dagger), E) \longrightarrow \mathrm{Fun}(A^{\mathit{eff}}(C, C_\dagger, C^\dagger), E)$$
induced by j is an equivalence, where $\mathscr{G}$ denotes the class of small sifted simplicial sets.

The following is now immediate from [31].

7.3. **Lemma.** *Suppose $(C, C_\dagger, C^\dagger)$ a disjunctive triple, and suppose E a presentable ∞-category in which filtered colimits are left exact. Then the inclusion functor*
$$A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \hookrightarrow \mathrm{D}A(C, C_\dagger, C^\dagger)$$
and the 0-th space functor $\Omega^\infty \colon \mathbf{Sp}(E) \longrightarrow E$ induce equivalences
$$\begin{array}{ccc} \mathrm{Fun}^{\mathrm{L}}(\mathrm{D}A(C, C_\dagger, C^\dagger), \mathbf{Sp}(E)) & \xrightarrow{\sim} & \mathbf{Mack}(C, C_\dagger, C^\dagger; \mathbf{Sp}(E)) \\ \| & & \\ \mathrm{Exc}_{\mathscr{F}}(\mathrm{D}A(C, C_\dagger, C^\dagger), \mathbf{Sp}(E)) & \xrightarrow{\sim} & \mathrm{Exc}_{\mathscr{F}}(\mathrm{D}A(C, C_\dagger, C^\dagger), E) \end{array}$$
where $\mathrm{Exc}_{\mathscr{F}}$ denotes the ∞-category of (1-)excisive functor that preserve all filtered colimits.

Now we are well positioned to obtain Mackey stabilizations.

7.4. **Proposition.** *Suppose $(C, C_\dagger, C^\dagger)$ a disjunctive triple, and suppose E a presentable ∞-category in which filtered colimits are left exact. Then any functor $f \colon A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \longrightarrow E$ admits a Mackey stabilization. In particular, the functor*
$$\Omega^\infty \circ - \colon \mathbf{Mack}(C, C_\dagger, C^\dagger; \mathbf{Sp}(E)) \longrightarrow \mathrm{Fun}(A^{\mathit{eff}}(C, C_\dagger, C^\dagger), E)$$
admits a left adjoint.

Proof. Compose the equivalences of the previous lemma with the 1-excisive approximation functor $P_1 \colon \mathrm{Fun}_{\mathscr{F}}(\mathrm{D}A(C, C_\dagger, C^\dagger), E) \longrightarrow \mathrm{Exc}_{\mathscr{F}}(\mathrm{D}A(C, C_\dagger, C^\dagger), E)$, which is left adjoint to the inclusion. Employing the equivalences of the previous lemma, a left adjoint to the inclusion functor
$$\mathbf{Mack}(C, C_\dagger, C^\dagger; \mathbf{Sp}(E)) \simeq \mathrm{Exc}_{\mathscr{F}}(\mathrm{D}A(C, C_\dagger, C^\dagger), E) \hookrightarrow \mathrm{Fun}_{\mathscr{F}}(\mathrm{D}A(C, C_\dagger, C^\dagger), E).$$
This left adjoint may now be composed with the inclusion
$$\mathrm{Fun}(A^{\mathit{eff}}(C, C_\dagger, C^\dagger), E) \simeq \mathrm{Fun}_{\mathscr{G}}(\mathrm{D}A(C, C_\dagger, C^\dagger), E) \hookrightarrow \mathrm{Fun}_{\mathscr{F}}(\mathrm{D}A(C, C_\dagger, C^\dagger), E)$$
to obtain the desired Mackey stabilization functor. □

Happily, Tom Goodwillie has provided us with a formula for the 1-excisive approximation [31, Cnstr. 7.1.1.27]. Hence for any functor $f \colon A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \longrightarrow E$, we obtain a formula for its Mackey stabilization as a 1-excisive functor $\Omega^\infty \circ F \colon \mathrm{D}A(C, C_\dagger, C^\dagger) \longrightarrow E$:
$$\Omega^\infty \circ F \simeq \operatorname*{colim}_{n \geq 0} \Omega^n \circ \overline{f} \circ \Sigma^n_{\mathrm{D}A(C, C_\dagger, C^\dagger)},$$

where $\overline{f}\colon \mathrm{D}A(C, C_{\dagger}, C^{\dagger}) \longrightarrow E$ is the essentially unique functor that preserves sifted colimits such that

$$\overline{f}|_{A^{\mathit{eff}}(C,C_{\dagger},C^{\dagger})} = f.$$

Consequently, we have the task of studying the suspension functor $\Sigma_{\mathrm{D}A(C,C_{\dagger},C^{\dagger})}$ on $\mathrm{D}A(C, C_{\dagger}, C^{\dagger})$. In particular, we are interested in its values on objects of the effective Burnside ∞-category. For any object $X \in A^{\mathit{eff}}(C, C_{\dagger}, C^{\dagger})$, we have a simplicial object $B_*(0, X, 0)$ given by

$$\mathbf{n} \longmapsto X^n,$$

whose geometric realization in $\mathrm{D}A(C, C_{\dagger}, C^{\dagger})$ is $\Sigma_{\mathrm{D}A(C,C_{\dagger},C^{\dagger})}X$. Since $\overline{f}$ preserves geometric realizations, we find

$$\Omega^{\infty}F(X) \simeq \operatorname*{colim}_{n\geq 0} \Omega^n \left(\operatorname*{colim}_{(\mathbf{k}_1,\dots,\mathbf{k}_n)\in(N\Delta^{op})^n} f\left(X^{k_1+\cdots+k_n}\right)\right).$$

In one important class of cases, it follows immediately from Segal's delooping machine that passage to the colimit is unnecessary.

7.5. **Proposition.** *Suppose $(C, C_{\dagger}, C^{\dagger})$ a disjunctive triple, and suppose E an ∞-topos. If $f\colon A^{\mathit{eff}}(C, C_{\dagger}, C^{\dagger}) \longrightarrow E$ is a functor that preserves finite products, the Mackey stabilization F of f is defined by the formula*

$$\Omega^{\infty}F(X) \simeq \Omega\big|B_*(*, f(X), *)\big|_{N\Delta^{op}},$$

where $B_*(*, f(X), *)$ is the simplicial object $\mathbf{k} \longmapsto f(X)^k$, and $|\cdot|_{N\Delta^{op}}$ denotes geometric realization.

8. Representable spectral Mackey functors and assembly morphisms

The Mackey stabilization is useful for constructing universal examples of Mackey functors.

8.1. **Definition.** Suppose $(C, C_{\dagger}, C^{\dagger})$ a disjunctive triple, and suppose X and object of C. Then the Mackey stabilization of the functor $A^{\mathit{eff}}(C, C_{\dagger}, C^{\dagger}) \longrightarrow \mathbf{Kan}$ corepresented by X will be denoted

$$\mathbf{S}^X_{(C,C_{\dagger},C^{\dagger})}\colon A^{\mathit{eff}}(C, C_{\dagger}, C^{\dagger}) \longrightarrow \mathbf{Sp}.$$

(We will drop the subscript and write $\mathbf{S}^X$ when the chosen disjunctive triple is clear from the context.) This is the ***Mackey functor corepresented by*** X

We will call the Mackey functor corepresented by the terminal object 1 the ***Burnside Mackey functor***. In this case, we drop the superscript and write simply $\mathbf{S}_{(C,C_{\dagger},C^{\dagger})}$.

The following is now an immediate consequence of the universal property of the Mackey stabilization.

8.2. **Proposition.** *Suppose $(C, C_{\dagger}, C^{\dagger})$ a disjunctive triple, and suppose X and object of C. Then the corepresentable Mackey functor has the universal property that for any Mackey functor $M\colon A^{\mathit{eff}}(C, C_{\dagger}, C^{\dagger}) \longrightarrow \mathbf{Sp}$, there is an identification*

$$\mathrm{Map}_{\mathbf{Mack}(C,C_{\dagger},C^{\dagger};\mathbf{Sp})}(\mathbf{S}^X, M) \simeq \Omega^{\infty}M(X),$$

functorial in M.

8.3. **Definition.** Suppose $(C, C_\dagger, C^\dagger)$ a disjunctive triple, suppose X and object of C, and suppose $M\colon A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \longrightarrow \mathbf{Sp}$ a Mackey functor. Then the identity functor $M(X) \longrightarrow M(X)$ defines a morphism of Mackey functors

$$\mathbf{S}^X \longrightarrow F(M(X), M),$$

where the target is the composite

$$A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \xrightarrow{M} \mathbf{Sp} \xrightarrow{F(M(X),-)} \mathbf{Sp}.$$

For any object $Y \in C$, we call the corresponding morphism

$$\alpha\colon \mathbf{S}^X(Y) \wedge M(X) \longrightarrow M(Y)$$

the ***assembly morphism*** for M, X, and Y.

9. Mackey stabilization via algebraic K-theory

Let us discuss a key circumstance in which we can express the Mackey stabilization (Df. 7.1) of a functor in terms of the additivization presented in [2, Df. 7.9]: we are interested in the situation in which a functor is given by composing a Mackey functor valued in Waldhausen ∞-categories with a suitable theory in the sense of [2, Df. 7.1].

9.1. **Definition.** Suppose $\phi\colon \mathbf{Wald}_\infty \longrightarrow \mathscr{E}$ a pre-additive theory [2, Df. 7.11]. Then we will say that a Waldhausen ∞-category $\mathscr{C}$ is ***ϕ-split*** if, for any integer $m \geq 0$, the functors $\mathscr{F}_m(\mathscr{C}) \longrightarrow \mathscr{C}$ and $\mathscr{F}_m(\mathscr{C}) \longrightarrow \mathscr{S}_m(\mathscr{C})$ induce an equivalence

$$\phi(\mathscr{F}_m(\mathscr{C})) \xrightarrow{\sim} \phi(\mathscr{C}) \times \phi(\mathscr{S}_m(\mathscr{C})).$$

9.2. **Proposition.** *Suppose $(C, C_\dagger, C^\dagger)$ a disjunctive triple, and suppose*

$$\mathscr{X}\colon A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \longrightarrow \mathbf{Wald}_\infty$$

a Mackey functor valued in the ∞-category of Waldhausen ∞-categories. Suppose, additionally, that $\mathscr{E}$ is an ∞-topos and $\phi\colon \mathbf{Wald}_\infty \longrightarrow \mathscr{E}$ a pre-additive theory such that for any object $s \in C$, the Waldhausen ∞-category is ϕ-split. Then the Mackey stabilization of the composite $\phi \circ \mathscr{X}$ is given by

$$s \longmapsto \mathbf{D}\phi(\mathscr{X}(s)),$$

where $\mathbf{D}\phi\colon \mathbf{Wald}_\infty \longrightarrow \mathbf{Sp}(\mathscr{E})$ denote the canonical lift of the additivization of [2, Cor. 7.6.1].

Proof. Let us extend $\phi \circ \mathscr{X}$ to a functor $\mathrm{D}A(C, C_\dagger, C^\dagger) \longrightarrow \mathscr{E}$ and compute the 1-excisive approximation. The Mackey stabilization of $\phi \circ \mathscr{X}$ is then the spectrum-valued lift of the 1-excisive approximation of the composite

$$\mathrm{D}A(C, C_\dagger, C^\dagger) \xrightarrow{\mathbf{L}\mathscr{X}} \mathrm{D}(\mathbf{Wald}_\infty) \xrightarrow{\Phi} \mathscr{E},$$

where Φ is the left derived functor of ϕ [2, Df. 4.14], and $\mathbf{L}\mathscr{X}$ is the essentially unique colimit-preserving functor whose restriction to $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)$ is $\mathscr{X}$. Then one has (by, for example, [31, Rk. 7.1.1.30])

$$P_1(\Phi \circ \mathbf{L}\mathscr{X}) \simeq P_1(\Phi) \circ \mathbf{L}\mathscr{X};$$

hence the Mackey stabilization of $\phi \circ \mathscr{X}$ is given by the spectrum-valued lift of the functor

$$s \longmapsto \operatorname{colim}_m \Omega^m \Phi \Sigma^m \mathscr{X}(s).$$

Here Σ denotes the suspension in $\mathrm{D}(\mathbf{Wald}_\infty)$. It can be computed by means of a bar construction:

$$\Sigma\mathscr{Y} \simeq |B_*(0, \mathscr{Y}, 0)|_{N\Delta^{op}},$$

where $B_n(0, \mathscr{Y}, 0) \simeq \mathscr{Y}^n$. Consequently, one may compute $\Phi \circ \Sigma$ as a geometric realization:

$$\Phi\Sigma(\mathscr{Y}) \simeq |B_*(*, \Phi(\mathscr{Y}), *)|_{N\Delta^{op}}.$$

Now let us assume further that for any object $s \in S$, the Waldhausen ∞-category $\mathscr{X}(s)$ is ϕ-split. In this case, one has

$$|B_*(*, \phi(\mathscr{X}(s)), *)|_{N\Delta^{op}} \simeq \Phi(\mathscr{S}\mathscr{X}(s)),$$

whence $\Omega\Phi\Sigma(\mathscr{X}(s))$ is the additivization [2, Df. 7.9] of ϕ applied to $\mathscr{X}(s)$. It follows that the colimit stabilizes, and the result follows. □

9.2.1. **Corollary.** *Suppose $(C, C_\dagger, C^\dagger)$ a disjunctive triple, and suppose*

$$\mathscr{X}\colon A^{\mathrm{eff}}(C, C_\dagger, C^\dagger) \longrightarrow \mathbf{Wald}_\infty$$

a Mackey functor valued in the ∞-category of Waldhausen ∞-categories. If each Waldhausen ∞-category $\mathscr{X}(s)$ is ι-split, then the Mackey stabilization of $\iota \circ \mathscr{X}$ is given by $\mathbf{K} \circ \mathscr{X}$, where $\mathbf{K}$ denotes connective algebraic K-theory.

10. Waldhausen bicartesian fibrations

We have already seen that there is a close relationship between algebraic K-theory and spectral Mackey functors. The inputs required there were Mackey functors valued in Waldhausen ∞-categories. Unfortunately, in nature, these Mackey functors tend not to appear with all of their coherences splayed out. Instead, the most interesting examples are found *furled* — as fibrations that exhibit both covariant functoriality and contravariant functoriality along with a compatibility between the two in certain situations. We call these fibrations *Waldhausen bicartesian fibrations*. In this section, we define this notion, and in the next, we show how to *unfurl* these fibrations to extract the desired Mackey functors valued in Waldhausen ∞-categories.

10.1**.** Suppose $p\colon X \longrightarrow S$ a cartesian and cocartesian fibration. Then for any morphism $f\colon s \longrightarrow t$ of S, one has and adjoint pair of functors

$$f_!\colon X_s \rightleftarrows X_t\colon f^\star.$$

For any square

$$\begin{array}{ccc} s & \xrightarrow{i} & s' \\ {\scriptstyle q}\downarrow & & \downarrow{\scriptstyle q'} \\ t & \xrightarrow[j]{} & t', \end{array} \tag{10.1.1}$$

the unit $\eta\colon \mathrm{id} \longrightarrow j^\star \circ j_!$ induces a natural transformation

$$q^\star \xrightarrow{q^\star(\eta)} q^\star \circ j^\star \circ j_! \simeq i^\star \circ q'^\star \circ j_!,$$

which is adjoint to a natural transformation

$$i_! \circ q^\star \longrightarrow q'^\star \circ j_!, \tag{10.1.2}$$

which we call the ***base change natural transformation***. Equivalently, we may construct this natural transformation by using the counit $\epsilon\colon q_! \circ q^\star \longrightarrow \mathrm{id}$ to define

$$q'_! \circ i_! \circ q^\star \simeq j_! \circ f_! \circ q^\star \xrightarrow{j_!(\epsilon)} j_!;$$

its right adjoint is then the base change natural transformation (10.1.2).

When the base change natural transformation is an equivalence, then one says that the square

$$\begin{array}{ccc} X_s & \xrightarrow{i_!} & X_{s'} \\ {\scriptstyle q_!}\downarrow & & \downarrow{\scriptstyle q'_!} \\ X_t & \xrightarrow[j_!]{} & X_{t'}, \end{array} \qquad \text{(respectively, the square} \qquad \begin{array}{ccc} X_{t'} & \xrightarrow{q'^\star} & X_{s'} \\ {\scriptstyle j^\star}\downarrow & & \downarrow{\scriptstyle i^\star} \\ X_t & \xrightarrow[q^\star]{} & X_s, \end{array} \quad)$$

is ***right adjointable*** (resp., ***left adjointable***) [25]. Apparently this is sometimes called the *Beck–Chevalley condition*.

If we only assume p an inner fibration, we can make sense of the base change natural transformation (10.1.2) in the presence of a small amount of extra information. Of course one needs to know that the functors $i_!$, $j_!$, $q^\star$, and $q'^\star$ all exist, and in order to construct (10.1.2), it is enough to assume *either* that the functors $q_!$ and $q'_!$ exist *or* that the functors $i^\star$ and $j^\star$. That is, if $\sigma\colon \Delta^1 \times \Delta^1 \longrightarrow S$ is given by the square (10.1.1), then it suffices to assume only *one* of the following.

(10.1.3) The functor

$$X \times_S (\Delta^1 \times \Delta^1) \longrightarrow \Delta^1 \times \Delta^1$$

is a cocartesian fibration, and the functor

$$X \times_S (\Delta^1 \times \partial\Delta^1) \longrightarrow \Delta^1 \times \partial\Delta^1$$

is a cartesian fibration.

(10.1.4) The functor

$$X \times_S (\Delta^1 \times \Delta^1) \longrightarrow \Delta^1 \times \Delta^1$$

is a cartesian fibration, and the functor

$$X \times_S (\partial\Delta^1 \times \Delta^1) \longrightarrow \partial\Delta^1 \times \Delta^1$$

is a cocartesian fibration.

We will apply this idea in the case that (10.1.1) is a square of a disjunctive triple in which the vertical morphisms q, q' of are egressive and the horizontal morphisms i, j are ingressive.

10.2. **Definition.** A triple $(C, C_\dagger, C^\dagger)$ is said to be ***left complete*** if $C_\dagger \subset C^\dagger$ and ***right complete*** if $C^\dagger \subset C_\dagger$.

In the examples of disjunctive triples of greatest interest to us, it is often the case that either every map is egressive or every map is ingressive. In particular, most of the examples of interest to us are either left complete or right complete.

Our equivariant K-theory will take as input assignments of Waldhausen ∞-categories to objects of disjunctive triples $(C, C_\dagger, C^\dagger)$ that are covariant in ingressive morphisms and contravariant in egressive morphisms. We will insist that for morphisms that are both ingressive and egressive, the resulting functors are adjoint. Finally, we will assume that for pullback squares of egressive morphisms along ingressive morphisms, the base change natural transformation is an equivalence. But for the base change natural transformation to make sense, we must assume that $(C, C_\dagger, C^\dagger)$ is either left or right complete. This leads us to the following.

10.3. **Definition.** Suppose $(C, C_\dagger, C^\dagger)$ an adequate triple that is either left complete or right complete. An inner fibration $p\colon X \longrightarrow C$ is said to be ***adequate over the triple*** $(C, C_\dagger, C^\dagger)$ if the following conditions obtain.

(10.3.1) For any ingressive morphism $f\colon s \rightarrowtail t$ and any object $x \in X_s$, there exists a p-cocartesian edge $x \longrightarrow y$ covering f. In particular, the functor

$$p_\dagger\colon X \times_C C_\dagger \longrightarrow C_\dagger$$

is a cocartesian fibration.

(10.3.2) For any egressive morphism $f\colon s \twoheadrightarrow t$ and any object $y \in X_t$, there exists a p-cartesian edge $x \longrightarrow y$ covering f. In particular, the functor

$$p^\dagger\colon X \times_C C^\dagger \longrightarrow C^\dagger$$

is a cartesian fibration.

(10.3.3) For any ambigressive pullback square

$$\begin{array}{ccc} s & \overset{i}{\rightarrowtail} & s' \\ {\scriptstyle q}\downarrow & & \downarrow{\scriptstyle q'} \\ t & \underset{j}{\rightarrowtail} & t', \end{array}$$

the base change natural transformation

$$i_! \circ q^\star \longrightarrow q'^\star \circ j_!$$

is an equivalence.

Suppose now that $(C, C_\dagger, C^\dagger)$ is a disjunctive triple that is either left complete or right complete. A ***Waldhausen bicartesian fibration over the triple*** $(C, C_\dagger, C^\dagger)$

$$q\colon \mathscr{X} \longrightarrow C$$

is a functor of pairs $\mathscr{X} \longrightarrow C^\flat$ that enjoys the following properties.

(10.3.4) The underlying functor $q\colon \mathscr{X} \longrightarrow C$ is an adequate inner fibration over the triple $(C, C_\dagger, C^\dagger)$.

(10.3.5) For any ingressive morphism $\eta\colon s \rightarrowtail t$, the induced functor $\eta_!\colon \mathscr{X}_s \longrightarrow \mathscr{X}_t$ carries cofibrations to cofibrations, and it is an exact functor

$$(\mathscr{X}_s, \mathscr{X}_s \times_{\mathscr{X}} \mathscr{X}_\dagger) \longrightarrow (\mathscr{X}_t, \mathscr{X}_t \times_{\mathscr{X}} \mathscr{X}_\dagger)$$

of Waldhausen ∞-categories.

(10.3.6) For any egressive morphism $\eta\colon s \twoheadrightarrow t$, the induced functor $\eta^\star\colon \mathscr{X}_t \longrightarrow \mathscr{X}_s$ carries cofibrations to cofibrations, and it is an exact functor

$$(\mathscr{X}_t, \mathscr{X}_t \times_{\mathscr{X}} \mathscr{X}_\dagger) \longrightarrow (\mathscr{X}_s, \mathscr{X}_s \times_{\mathscr{X}} \mathscr{X}_\dagger)$$

of Waldhausen ∞-categories.

(10.3.7) For any finite set I and any collection $\{s_i \mid i \in I\}$ of objects of C indexed by the elements of I with coproduct s, the functors

$$j_i^\star\colon \mathscr{X}_s \longrightarrow \mathscr{X}_{s_i}$$

induced by the inclusions $j_i\colon s_i \hookrightarrow s$ together exhibit $\mathscr{X}_s$ as the direct sum $\bigoplus_{i \in I} \mathscr{X}_{s_i}$.

The following lemma is just an unwinding of the relevant definitions, but it will come in handy later.

10.4. **Lemma.** *Suppose $(C, C_\dagger, C^\dagger)$ an adequate triple that is either left or right complete. If $p\colon X \longrightarrow C$ is an inner fibration satisfying conditions (10.3.1) and (10.3.2), then condition (10.3.3) is equivalent to the condition that for any square*

$$\begin{array}{ccc} x & \overset{\eta}{\rightarrowtail} & x' \\ {\scriptstyle\alpha}\downarrow & & \downarrow{\scriptstyle\alpha'} \\ y & \underset{\theta}{\rightarrowtail} & y' \end{array}$$

of $\mathscr{X}$ that covers an ambigressive pullback square

$$\begin{array}{ccc} s & \overset{i}{\rightarrowtail} & s' \\ {\scriptstyle q}\downarrow & & \downarrow{\scriptstyle q'} \\ t & \underset{j}{\rightarrowtail} & t' \end{array}$$

of C, if α and α' are p-cartesian and θ is p-cocartesian, then η is also p-cocartesian.

11. Unfurling

Here is the central construction of this paper. A Waldhausen bicartesian fibration over a left or right complete disjunctive triple $(C, C_\dagger, C^\dagger)$ has all the elements that we might look for in a Mackey functor valued in Waldhausen ∞-categories: there's a covariant functor $C_\dagger \longrightarrow \mathbf{Wald}_\infty$ and a contravariant functor $(C^\dagger)^{op} \longrightarrow \mathbf{Wald}_\infty$, and the two are glued via base change equivalences. Unfortunately, these data are not displayed in a fashion that makes it easy to spot the functoriality in the effective Burnside ∞-category $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)$. In order to extract something that is visibly functorial in the effective Burnside ∞-category, we must perform an operation, which we call *unfurling*. When we unfurl a Waldhausen bicartesian fibration $\mathscr{X} \longrightarrow C$ for the triple $(C, C_\dagger, C^\dagger)$, we end up with a Waldhausen cocartesian fibration $\Upsilon(\mathscr{X}/(C, C_\dagger, C^\dagger)) \longrightarrow A^{\mathit{eff}}(C, C_\dagger, C^\dagger)$, which we may then straighten into a Mackey functor on $(C, C_\dagger, C^\dagger)$ valued in Waldhausen ∞-categories.

11.1. **Notation.** Suppose $(C, C_\dagger, C^\dagger)$ a triple, and suppose $p\colon X \longrightarrow C$ an inner fibration. Denote by $X_\dagger \subset X \times_C C_\dagger$ (respectively, $X^\dagger \subset X \times_C C^\dagger$) the subcategory containing all the objects whose morphisms are p-cocartesian (resp., p-cartesian).

11.2. **Proposition.** *Suppose $(C, C_\dagger, C^\dagger)$ an adequate triple (Df. 5.2), and suppose $p\colon X \longrightarrow C$ an adequate inner fibration over $(C, C_\dagger, C^\dagger)$ (Df. 10.3). Then the triples $(X, X \times_C C_\dagger, X^\dagger)$ and $(X, X_\dagger, X \times_C C^\dagger)$ are adequate as well.*

Proof. We show that $(X, X \times_C C_\dagger, X^\dagger)$ is adequate; the case of $(X, X_\dagger, X \times_C C^\dagger)$ is dual. Suppose $\sigma\colon \Delta^1 \times \Delta^1 \longrightarrow C$ an ambigressive pullback

$$\begin{array}{ccc} s' & \rightarrowtail & t' \\ \downarrow & & \downarrow \\ s & \rightarrowtail & t, \end{array}$$

and suppose $x \rightarrowtail y$ a morphism covering $s \rightarrowtail t$ and $y' \twoheadrightarrow y$ a p-cartesian edge covering $t' \longrightarrow t$. Then there exists a p-cartesian edge $x' \twoheadrightarrow x$ covering $s' \longrightarrow s$, and after filling in the inner horn $x' \longrightarrow x \longrightarrow y$ and the outer horn $x' \longrightarrow y \longleftarrow y'$ (using the p-cartesianness of $y' \twoheadrightarrow y$), we obtain a pullback square

$$\begin{array}{ccc} x' & \rightarrowtail & y' \\ \downarrow & & \downarrow \\ x & \rightarrowtail & y \end{array}$$

covering σ. ☐

11.3. **Definition.** Suppose $(C, C_\dagger, C^\dagger)$ an adequate triple, and suppose $p\colon X \longrightarrow C$ an adequate inner fibration over $(C, C_\dagger, C^\dagger)$. Then the ***unfurling*** of p is the ∞-category

$$\Upsilon(X/(C, C_\dagger, C^\dagger)) := A^{eff}(X, X \times_C C_\dagger, X^\dagger).$$

Composition with p defines a natural map

$$\Upsilon(p)\colon \Upsilon(X/(C, C_\dagger, C^\dagger)) \longrightarrow A^{eff}(C, C_\dagger, C^\dagger).$$

We'll prove the following brace of lemmas in the next section.

11.4. **Lemma.** *Suppose $(C, C_\dagger, C^\dagger)$ an adequate triple, and suppose $p\colon X \longrightarrow C$ an adequate inner fibration over $(C, C_\dagger, C^\dagger)$. Then*

$$\Upsilon(p)\colon \Upsilon(X/(C, C_\dagger, C^\dagger)) \longrightarrow A^{eff}(C, C_\dagger, C^\dagger)$$

is an inner fibration.

11.5. **Lemma.** *Suppose $(C, C_\dagger, C^\dagger)$ an adequate triple, and suppose $p\colon X \longrightarrow C$ an adequate inner fibration over $(C, C_\dagger, C^\dagger)$. An edge $f : y \longrightarrow z$ of $\Upsilon(X/(C, C_\dagger, C^\dagger))$ is $\Upsilon(p)$-cocartesian if it is represented as a span*

$$\begin{array}{ccccc} & & u & & \\ & \overset{\phi}{\swarrow} & & \overset{\psi}{\searrow} & \\ y & & & & z, \end{array}$$

in which ϕ is p-cartesian over an egressive morphism and ψ is p-cocartesian over an ingressive morphism.

The following is now immediate.

11.6. **Proposition.** *Suppose $(C, C_\dagger, C^\dagger)$ an adequate triple that is either left or right complete, and suppose*

$$p\colon \mathscr{X} \longrightarrow C$$

an adequate inner fibration over $(C, C_\dagger, C^\dagger)$. Then the unfurling $\Upsilon(p)$ is a cocartesian fibration.

More particularly, for any disjunctive triple $(C, C_\dagger, C^\dagger)$ that is either left or right complete (Df. 10.2), and for any Waldhausen bicartesian fibration $p\colon \mathscr{X} \longrightarrow C$ over $(C, C_\dagger, C^\dagger)$ (Df. 10.3), it follows that $\Upsilon(p)$ is a cocartesian fibration. Moreover, for any object s of C, consider the functor $\mathscr{X}_s \longrightarrow \Upsilon(\mathscr{X}/(C, C_\dagger, C^\dagger))_s$ induced by the natural transformation $\varepsilon^\star \longrightarrow op$. This functor is the identity on objects, and it is easy to see that it is fully faithful. Now for any $s \longrightarrow t$ of $A^{\mathrm{eff}}(C, C_\dagger, C^\dagger)$ represented as a span

$$\begin{array}{ccc} & u & \\ {\scriptstyle f}\swarrow & & \searrow{\scriptstyle g} \\ s & & t, \end{array}$$

in C, the induced functor

$$\mathscr{X}_s \simeq \Upsilon(\mathscr{X}/(C, C_\dagger, C^\dagger))_s \longrightarrow \Upsilon(\mathscr{X}/(C, C_\dagger, C^\dagger))_t \simeq \mathscr{X}_t$$

is equivalent to $g_! \circ f^\star$. In particular, it is exact, whence we have the following.

11.7. **Proposition.** *Suppose* $(C, C_\dagger, C^\dagger)$ *a disjunctive triple that is either left or right complete, and suppose*

$$p\colon \mathscr{X} \longrightarrow C$$

a Waldhausen bicartesian fibration over $(C, C_\dagger, C^\dagger)$*. Then the unfurling* $\Upsilon(p)$ *is a Waldhausen cocartesian fibration.*

Now condition (10.3.2) immediately implies the main feature of unfurlings.

11.8. **Theorem.** *Suppose* $(C, C_\dagger, C^\dagger)$ *a disjunctive triple, and suppose*

$$p\colon \mathscr{X} \longrightarrow C$$

a Waldhausen bicartesian fibration over $(C, C_\dagger, C^\dagger)$*. Then a functor*

$$\mathscr{M}_p\colon A^{\mathrm{eff}}(C, C_\dagger, C^\dagger) \longrightarrow \mathbf{Wald}_\infty$$

that classifies the unfurling $\Upsilon(p)$ *is a Mackey functor.*

One may compose a functor classifying the unfurling of a Waldhausen bicartesian fibration with the delooping $\mathbf{Wald}_\infty \longrightarrow \mathbf{Sp}$ of any additive theory to obtain the following.

11.8.1. **Corollary.** *Suppose* $(C, C_\dagger, C^\dagger)$ *a disjunctive triple, and suppose*

$$p\colon \mathscr{X} \longrightarrow C$$

a Waldhausen bicartesian fibration over $(C, C_\dagger, C^\dagger)$*. Suppose*

$$\mathscr{M}_p\colon A^{\mathrm{eff}}(C, C_\dagger, C^\dagger) \longrightarrow \mathbf{Wald}_\infty$$

a functor that classifies the unfurling $\Upsilon(p)$*. Then for any additive theory*

$$F\colon \mathbf{Wald}_\infty \longrightarrow \mathscr{E}$$

in the sense of [2, Df. 7.1]*, the composition*

$$\mathbf{F} \circ \mathscr{M}_p\colon A^{\mathrm{eff}}(C, C_\dagger, C^\dagger) \longrightarrow \mathbf{Sp}(\mathscr{E}),$$

where $\mathbf{F}\colon \mathbf{Wald}_\infty \longrightarrow \mathbf{Sp}(\mathscr{E})$ *is the canonical delooping of* F [2, Cor. 7.6.1]*, is a Mackey functor.*

In particular, we see that the algebraic K-theory of a Waldhausen bicartesian fibration naturally organizes itself into a Mackey functor valued in spectra.

12. Horn filling in effective Burnside ∞-categories

In both Lm. 11.4 and Lm. 11.5, we are interested in filling horns in effective Burnside ∞-categories. These correspond to extensions along inclusions of the form $\widetilde{\mathscr{O}}(\Lambda^m_k)^{op} \hookrightarrow \widetilde{\mathscr{O}}(\Delta^m)^{op}$ that enjoy certain properties. In this section, we construct a filtration that provides a general strategy for constructing the desired extensions, and we use this to prove Lms. 11.4 and 11.5.

The reader uninterested in such nitty-gritty may be forgiven for skipping this section; however, one must acknowledge that this is where the rubber meets the road. Ultimately, it is the combinatorics of simplices that allow us to solve homotopy-coherence problems.

12.1. **Notation.** In this section, let $(C, C_\dagger, C^\dagger)$ and $(D, D_\dagger, D^\dagger)$ denote two adequate triples, and let $p\colon (C, C_\dagger, C^\dagger) \longrightarrow (D, D_\dagger, D^\dagger)$ be a functor of triples that carries ambigressive pullbacks to ambigressive pullbacks. Write $p_\dagger$ for the restriction $C_\dagger \longrightarrow D_\dagger$, and write $p^\dagger$ for the restriction $C^\dagger \longrightarrow D^\dagger$.

Here is what we will prove.

12.2. **Theorem.** *Assume that the underlying functor $C \longrightarrow D$ is an inner fibration. Then the induced functor*

$$A^{eff}(p)\colon A^{eff}(C, C_\dagger, C^\dagger) \longrightarrow A^{eff}(D, D_\dagger, D^\dagger)$$

is an inner fibration.

Furthermore, assume the following.

(12.2.1) For any ingressive morphism $g\colon s \rightarrowtail t$ of D and any object $x \in C_s$, there exists an ingressive morphism $f\colon x \rightarrowtail y$ of C covering g that is both p-cocartesian and $p_\dagger$-cocartesian.

(12.2.2) Suppose σ a commutative square

$$\begin{array}{ccc} x' & \overset{f'}{\rightarrowtail} & y' \\ {\scriptstyle\phi}\downarrow & & \downarrow{\scriptstyle\psi} \\ x & \underset{f}{\rightarrowtail} & y, \end{array}$$

of C such that the square $f(\sigma)$ is an ambigressive pullback in D, the morphism f' is ingressive, the morphism ϕ is egressive, and the morphism f is p-cocartesian. Then f' is p-cocartesian if and only if the square is an ambigressive pullback (and in particular ψ is egressive).

Then an edge $f\colon y \longrightarrow z$ of $A^{eff}(C, C_\dagger, C^\dagger)$ is $A^{eff}(p)$-cocartesian if it is represented as a span

$$y \xleftarrow{\ \phi\ } u \xrightarrow{\ \psi\ } z,$$

in which ϕ is egressive and p-cartesian and ψ is ingressive and p-cocartesian.

The proof will occupy the entirety of this section. This implies both Lm. 11.4 and Lm. 11.5 as special cases. (Note that (12.2.2) is an immediate consequence of the Beck–Chevvaley condition (10.3.3).) This result may also be used to give an alternative argument that $A^{eff}(C, C_\dagger, C^\dagger)$ is an ∞-category.

12.3. **Notation.** Suppose $m \geq 2$ and suppose $0 \leq k < m$ (note that we are excluding the case $k = m$), and suppose we are given a commutative square

$$\begin{array}{ccc} \Lambda^m_k & \longrightarrow & A^{eff}(C, C_\dagger, C^\dagger). \\ \big\downarrow & & \big\downarrow{\scriptstyle A^{eff}(p)} \\ \Delta^m & \longrightarrow & A^{eff}(D, D_\dagger, D^\dagger), \end{array}$$

and we seek a lift $\Delta^m \longrightarrow A^{eff}(C, C_\dagger, C^\dagger)$. This corresponds to a (solid) commutative square

$$\begin{array}{ccc} \widetilde{\mathscr{O}}(\Lambda^m_k)^{op} & \xrightarrow{g} & C \\ \big\downarrow & \overset{\overline{g}}{\nearrow} & \big\downarrow{\scriptstyle p} \\ \widetilde{\mathscr{O}}(\Delta^m)^{op} & \xrightarrow[h]{} & D \end{array}$$

of simplicial sets in which h is ambigressive cartesian and, for every $i \neq k$, the restriction

$$\widetilde{\mathscr{O}}(\Delta^{\{0,\dots,\hat{\imath},\dots,m\}})^{op} \subset \widetilde{\mathscr{O}}(\Lambda^m_k)^{op} \xrightarrow{g} C$$

is ambigressive cartesian. Our objective then becomes to construct a (dotted) lift

$$\overline{g} \colon \widetilde{\mathscr{O}}(\Delta^m)^{op} \longrightarrow C$$

that is ambigressive cartesian.

12.4. **Definition.** Let us call a m-simplex

$$i_0 j_0 \longrightarrow i_1 j_1 \longrightarrow \cdots \longrightarrow i_m j_m$$

of $\widetilde{\mathscr{O}}(\Delta^m)^{op}$ ***completely factored*** if $i_r - i_{r-1} + j_{r-1} - j_r = 1$ for each $1 \leq r \leq m$. Note that any complete m-simplex is in particular nondegenerate, and $i_0 = 0$ and $j_0 = m$.

12.5**.** Completely factored m-simplices are essentially the same as walks on the poset $\widetilde{\mathscr{O}}([\mathbf{m}])^{op}$ that begin at the point $0m$ and end at a point of the form pp. We may therefore parametrize the completely factored m-simplices as follows. For each integer $0 \leq N \leq 2^m - 1$, let $\sigma(N)$ be the unique completely factored m-simplex

$$i_0 j_0 \longrightarrow i_1 j_1 \longrightarrow \cdots \longrightarrow i_m j_m$$

such that if d_r is the r-th binary digit of N (read left to right, so that $N = \sum_{s=1}^{m} 2^{m-s} d_s$), then

$$d_r = \begin{cases} 0 & \text{if } i_{r-1} = i_r; \\ 1 & \text{if } j_{r-1} = j_r. \end{cases}$$

We order these simplices accordingly. Hence $\sigma(N)$ is the m-simplex

$$i_0 j_0 \longrightarrow i_1 j_1 \longrightarrow \cdots \longrightarrow i_m j_m$$

with

$$i_r = \sum_{s=1}^{r} d_s \quad \text{and} \quad j_r = (m - r) + \sum_{s=1}^{r} d_s.$$

Fig. 1 shows the completely factored 5-simplex $\sigma(01101) = \sigma(13) \subset \widetilde{\mathscr{O}}(\Delta^m)^{op}$.

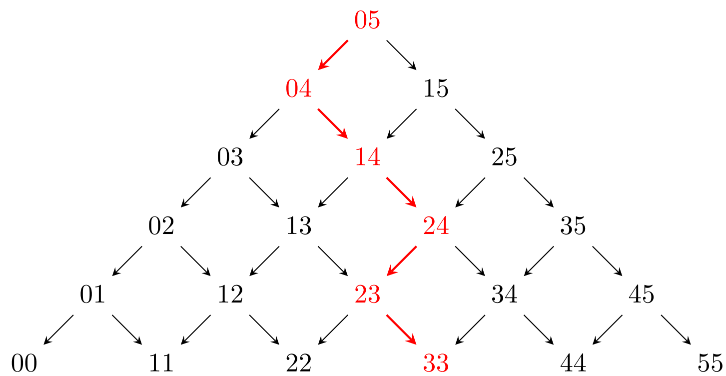


Figure 1. The completely factored 5-simplex $\sigma(01101) = \sigma(13) \subset \widetilde{\mathscr{O}}(\Delta^5)^{op}$, drawn in red as a walk from 05 to 33. The juts of this 5-simplex are 3 and 5. There are no crossings away from 1; if $k \neq 1$, the only crossing away from 1 is 2.

Now for any integer $0 \leq N \leq 2^m$, write

$$P_N(k) := \widetilde{\mathscr{O}}(\Lambda^m_k)^{op} \cup \bigcup_{0 \leq K < N} \sigma(K);$$

this provides a filtration

$$\widetilde{\mathscr{O}}(\Lambda^m_k)^{op} = P_0(k) \subset \cdots \subset P_{2^m}(k) = \widetilde{\mathscr{O}}(\Delta^m)^{op}.$$

Our aim is to find conditions that permit us to extend g along this filtration.

We proceed to analyze the intersections $\sigma(N) \cap P_N(k)$ as a subset of $\sigma(N) \cong \Delta^m$. We will find that each $\sigma(N) \cap P_N(k)$ is in fact a union of faces of Δ^m. There are two kinds of faces that will appear in this intersection. To describe these, let's introduce some simplifying notation.

12.6. **Notation.** For any nonempty totally ordered finite set T and any element $j \in T$, write $\Delta^{\hat{\jmath}}$ for the face

$$\Delta^{T-\{j\}} \subset \Delta^T.$$

More generally, for any ordered subsets $S \subset T$, write $\Lambda^T_S \subset \Delta^T$ for the union of all the faces (i.e., $\#T$-simplices) of Δ^T that contain the simplex Δ^S. In other words, let

$$\Lambda^T_S := \bigcup_{j \notin S} \Delta^{\hat{\jmath}}.$$

When $T = \{0, \ldots, m\}$, we just write Λ^m_S for Λ^T_S.

In this notation, we have

$$\sigma(N) \cap P_N(k) = \left(\bigcup_{0 \leq K < N} \sigma(N) \cap \sigma(K) \right) \cup \left(\bigcup_{j \neq k} \sigma(N) \cap \widetilde{\mathscr{O}}(\Delta^{\hat{\jmath}})^{op} \right),$$

and our claim is that there is a set $E(N,k) \subset \{0, \ldots, m\}$ such that

$$\sigma(N) \cap P_N(k) = \Lambda^m_{E(N,k)}.$$

We proceed to construct this set now.

12.7. **Definition.** Suppose N an integer such that $0 \leq N \leq 2^m - 1$, written as $N = \sum_{s=1}^{m} 2^{m-s} d_s$. A ***jut*** of the completely factored m-simplex $\sigma(N)$ is an integer $z \in \{1, \dots, m\}$ such that

- $d_z = 1$, and
- either $d_{z+1} = 0$ or $z = m$.

Denote by $Z(N) \subset \{1, \dots, m\}$ the set of juts of $\sigma(N)$.

For any jut z, write

$$K_z = \sum_{s=1}^{m} 2^{m-s} d_{z,s},$$

where

$$d_{z,s} = \begin{cases} d_s & \text{if } s \notin \{z, z+1\}; \\ 0 & \text{if } s = z; \\ 1 & \text{if } s = z+1. \end{cases}$$

12.8. **Lemma.** *Suppose N an integer such that $0 \leq N \leq 2^m - 1$, written as $N = \sum_{s=1}^{m} 2^{m-s} d_s$. Then*

$$\bigcup_{0 \leq K < N} \sigma(N) \cap \sigma(K) = \bigcup_{z \in Z(N)} \Delta^{\hat{z}}.$$

Proof. It is easy to see that in the poset of simplicial subsets of $\sigma(N)$ of the form $\sigma(N) \cap \sigma(K)$, the maximal elements consist of those subsets of the form $\sigma(N) \cap \sigma(K_z)$, where z in a jut of $\sigma(N)$. Of course $\Delta^{\hat{z}} = \sigma(N) \cap \sigma(K_z)$. □

12.9. **Definition.** Suppose N an integer such that $0 \leq N \leq 2^m - 1$ written as $N = \sum_{s=1}^{m} 2^{m-s} d_s$. A ***crossing*** of $\sigma(N)$ away from k is an integer $x \in \{0, \dots, m-1\}$ such that one of the following holds:

- $x = 0$, $d_1 = 0$;
- $x = 0$, $d_1 = 1$, and $k \neq 0$;
- $x > 0$, $d_x = d_{x+1} = 1$, and $i_x \neq k$; or
- $x > 0$, $d_x = d_{x+1} = 0$ and $j_x \neq k$.

Denote by $X(N, k) \subset \{0, \dots, m-1\}$ the set of crossings away from k.

The crossings away from k are now all we need to complete our computation of the intersections $\sigma(N) \cap P_N(k)$.

12.10. **Proposition.** *Suppose N an integer such that $0 \leq N \leq 2^m - 1$, written as $N = \sum_{s=1}^{m} 2^{m-s} d_s$. Then*

$$\sigma(N) \cap P_N(k) = \bigcup_{y \in Z(N) \cup X(N,k)} \Delta^{\hat{y}}.$$

Proof. For any crossing x of $\sigma(N)$ away from k, it is clear that the corresponding face is given by

$$\Delta^{\hat{x}} = \begin{cases} \sigma(N) \cap \widetilde{\mathscr{O}}(\Delta^{\hat{\imath}_x})^{op} & \text{if } d_x = 1; \\ \sigma(N) \cap \widetilde{\mathscr{O}}(\Delta^{\hat{\jmath}_x})^{op} & \text{if } d_x = 0. \end{cases}$$

Now for any $j \in \{0, \dots, m\}$, if the set

$$\{r \in \{0, \dots, m\} \mid i_r = j \text{ or } j_r = j\}$$

contains more than one element, then it contains a jut z, and consequently,

$$\sigma(N) \cap \widetilde{\mathscr{O}}(\Delta^{\hat{j}})^{op} \subset \Delta^{\hat{z}} = \sigma(N) \cap \sigma(K_z). \qquad \square$$

12.11. **Warning.** Note that this doesn't quite work if $k = m$ (which we expressly excluded): in this case it is just not true that $\sigma(N) \cap P_N(k)$ is a union of faces. For example, in the completely factored 5-simplex $\sigma(13)$ depicted in Fig. 1, if $k = 5$, then the simplicial subset $\sigma(13) \cap P_{13}(5) \subset \sigma(13)$ is the union

$$\Delta^{\hat{3}} \cup \Delta^{\hat{5}} \cup \Delta^{\{2,3,4,5\}}.$$

Let us reformulate what we have shown.

12.12. **Definition.** Suppose N an integer such that $0 \leq N \leq 2^m - 1$ written as $N = \sum_{s=1}^{m} 2^{m-s} d_s$. Let us call an integer $s \in \{0, \dots, m\}$ an ***essential vertex*** of $\sigma(N)$ for k if it is neither a jut nor a crossing away from k. Denote by

$$E(N, k) := \{0, \dots, m\} - (Z(N) \cup X(N, k))$$

the ordered set of essential vertices of $\sigma(N)$ for k.

We have thus shown that we may write

$$\sigma(N) \cap P_N(k) = \Lambda^m_{E(N,k)} \subset \Delta^m \cong \sigma(N).$$

Now we want to extend g along each inclusion $P_{N-1}(k) \hookrightarrow P_N(k)$, which we now write as pushout

$$\begin{array}{ccc} \Lambda^m_{E(N,k)} & \longrightarrow & \Delta^m \\ \downarrow & & \downarrow \\ P_N(k) & \longrightarrow & P_{N+1}(k). \end{array}$$

For this, we need to determine just what sort of inclusions these ore. For example, if $\Lambda^m_{E(N,k)} \hookrightarrow \Delta^m$ is inner anodyne, one has the desired extension simply because p is an inner fibration. Let's determine precisely when this does the job.

12.13. **Lemma.** *Suppose $S \subset \{0, \dots, m\}$ a nonempty ordered subset. Then the inclusion $\Lambda^m_S \hookrightarrow \Delta^m$ is inner anodyne if the following condition holds.*

(∗) *there exists elements $a < s < b$ of $\{0, \dots, m\}$ such that $s \in S$, but $a, b \notin S$.*

Proof. The claim is trivial if either $m = 2$ or S has cardinality 1. For $m \geq 3$ and $\#S \geq 2$, assume that the result holds both for all smaller values of m and for subsets S of smaller cardinality.

Choose an element $s \in S$ as follows: if $0 \in S$, let $s = 0$; otherwise, if $m \in S$, let $s = m$; otherwise choose $s \in S$ arbitrarily. Then the subset

$$S - \{s\} \subset \{0, \dots, \widehat{s}, \dots, m\}$$

satisfies condition (∗) for $m - 1$; hence the inclusion

$$\Lambda^m_S \cap \Delta^{\hat{s}} = \Lambda^{\{0,\dots,\widehat{s},\dots,m\}}_{S-\{s\}} \hookrightarrow \Delta^{\{0,\dots,\widehat{s},\dots,m\}}$$

is inner anodyne by the inductive hypothesis. The pushout of this edge along the inclusion

$$\Lambda^m_S \cap \Delta^{\hat{s}} \hookrightarrow \Lambda^m_S$$

is the inclusion

$$\Lambda^m_S \hookrightarrow \Lambda^m_{S-\{s\}},$$

which is thus inner anodyne. Now our claim follows from the observation that the subset $S-\{s\} \subset \{0, \ldots, m\}$ also satisfies condition $(*)$, whence the inclusion

$$\Lambda^m_{S-\{s\}} \hookrightarrow \Delta^m$$

is also inner anodyne by the inductive hypothesis. □

Suppose N an integer such that $0 \leq N \leq 2^m - 1$ written as $N = \sum_{s=1}^m 2^{m-s} d_s$. We have shown that if $E(N,k)$ satisfies condition $(*)$, then $P_N(k) \hookrightarrow P_{N+1}(k)$ is inner anodyne. If however $E(N,k)$ fails condition $(*)$, let's refer to $\sigma(N)$ as an ***exceptional case***.

Indeed, such an m-simplex is quite exceptional: it cannot contain more than one jut, since there must be an essential vertex between any two juts. Consequently, for any $t \in \{0, \ldots, m\}$, if

$$d_s = \begin{cases} 1 & \text{if } s \leq t; \\ 0 & \text{if } s > t, \end{cases}$$

then let's write $N_t := \sum_{s=1}^m 2^{m-s} d_s$. Then $\sigma(N_t)$ is the walk

$$0m \longrightarrow 1m \longrightarrow \cdots \longrightarrow tm \longrightarrow t(m-1) \cdots \longrightarrow tt.$$

One thus sees that any exceptional case is of the form $\sigma(N_t)$.

Furthermore, the simplex $\sigma(N_t)$ begins with a crossing if either $k \neq 0$ or $N_t < 2^{m-1}$, so $0 \in E(N_t, k)$ if and only if both $k = 0$ and $N_t \geq 2^{m-1}$. Dually, $\sigma(N_t)$ ends in a jut precisely when N_t is odd, so $m \in E(k)$ if and only if N_t is even. Now a quick analysis of the location of the crossings away from k yields the following classification of all the exceptional cases.

12.14. **Proposition.** *When $k \neq 0$, there are only two exceptional cases:*

(12.14.1) $t = k-1$, *in which case* $E(N_{k-1}, k) = \{m-1, m\}$.
(12.14.2) $t = k$, *in which case* $E(N_k, k) = \{m\}$.

When $k = 0$, there are $t+1$ exceptional cases:

(12.14.3) $t = 0$, *in which case* $E(0,0) = \{m\}$.
(12.14.4) $0 < t < m$, *in which case* $E(N_t, 0) = \{0, m\}$.
(12.14.5) $t = m$, *in which case* $E(2^m - 1, 0) = \{0\}$.

To illustrate, in Fig. 2, the two exceptional cases in $\widetilde{\mathscr{O}}(\Delta^5)^{op}$ for $k = 3$ are depicted.

We can now begin the proof of Th. 12.2. Here is the first bit.

12.15. **Lemma.** *Suppose $0 < k < m$. Then there exists a (dotted) lift*

$$\begin{array}{ccc} \widetilde{\mathscr{O}}(\Lambda^m_k)^{op} & \xrightarrow{g} & C \\ \downarrow & \overset{\overline{g}}{\nearrow} & \downarrow p \\ \widetilde{\mathscr{O}}(\Delta^m)^{op} & \xrightarrow[h]{} & D \end{array}$$

Proof. Let's handle the case $m = 2$ separately. Note that $\widetilde{\mathscr{O}}(\Delta^2)^{op} = (\widetilde{\mathscr{O}}(\Delta^2_1)^{op})^{\triangleleft}$, so we may form the desired lift $\overline{g}$ simply by forming the p-limit in the sense of [25, Df. 4.3.1.1].

For $m \geq 3$, of course we will proceed by induction on the filtration

$$\widetilde{\mathscr{O}}(\Lambda^m_k)^{op} = P_0(k) \subset \cdots \subset P_{2^m}(k) = \widetilde{\mathscr{O}}(\Delta^m)^{op}.$$

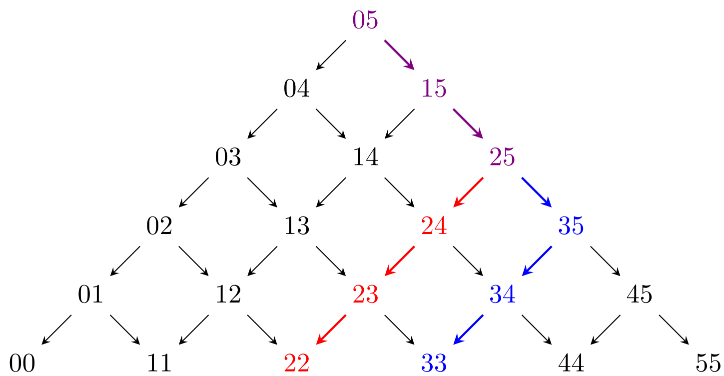

FIGURE 2. The two exceptional cases $\sigma(N_2)$ and $\sigma(N_3)$ for $k = 3$ in $\widetilde{\mathscr{O}}(\Delta^5)^{op}$, drawn in red and blue (respectively) as walks from 05 to 22 and from 05 to 33.

Given a lift

$$\begin{array}{ccc} \widetilde{\mathscr{O}}(\Lambda^m_k)^{op} & \xrightarrow{g} & C \\ \downarrow & \nearrow_{g_N} & \downarrow p \\ P_N(k) & \xrightarrow[h|P_N(k)]{} & D, \end{array}$$

we seek a (dotted) lift

$$\begin{array}{ccc} P_N(k) & \xrightarrow{g_N} & C \\ \downarrow & \nearrow_{g_{N+1}} & \downarrow p \\ P_{N+1}(k) & \xrightarrow[h|P_{N+1}(k)]{} & D. \end{array}$$

The only catch will be that we must choose the extensions to the exceptional m-simplices and some of their neighbors carefully.

To begin, for $0 \leq N < N_{k-1}$, we use the right lifting property with respect to the inner anodyne inclusions $\sigma(N) \cap P_N(k) \hookrightarrow \sigma(N)$ to obtain the desired lift

$$g_{N_{k-1}} \colon P_{N_{k-1}}(k) \longrightarrow C.$$

Now let us call a completely factored m-simplex $\sigma(N)$ ***special*** just in case the corresponding integer $N = \sum_{s=1}^{m} 2^{m-s} d_s$ has the property that $d_s = 1$ for every $1 \leq s \leq k-1$, and no more than one of $d_k, \ldots, d_m$ is equal to 1. Let $R(k)$ be the collection of those N such that $\sigma(N)$ is special. Note that the exceptional m-simplex $\sigma(N_{k-1})$ of (12.14.1) is the first special m-simplex, and the exceptional m-simplex $\sigma(N_k)$ of (12.14.2) is the last special m-simplex. Also observe that for any $N \in R(k)$, one has

$$\sigma(N) \cap P_N = (\sigma(N) \cap P_{N_{k-1}}) \cup \bigcup_{K \in R(k),\ K<N} (\sigma(N) \cap \sigma(K)).$$

Now we have a functor

$$f_k \colon \Delta^1 \times \Delta^{m-1} \longrightarrow \widetilde{\mathscr{O}}(\Delta^m)^{op}$$

that is determined on its value on objects:

$$f_k(u,v) := (\max\{0, v-k+1\}, \max\{m-v-u, k-u\}).$$

The functor f_k restricts to a functor

$$(\Delta^1 \times \Lambda^{m-1}_{m-1}) \cup^{(\Delta^{\{1\}} \times \Lambda^{m-1}_{m-1})} (\Delta^{\{1\}} \times \Delta^{m-1}) \longrightarrow P_{N_{k-1}}(k).$$

Note that (dotted) lifts in the diagram

$$\begin{array}{ccc} (\Delta^1 \times \Lambda^{m-1}_{m-1}) \cup^{(\Delta^{\{1\}} \times \Lambda^{m-1}_{m-1})} (\Delta^{\{1\}} \times \Delta^{m-1}) & \xrightarrow{g_{N_{k-1}}} & C \\ \downarrow & \overset{g'}{\nearrow} & \downarrow p \\ \Delta^1 \times \Delta^{m-1} & \xrightarrow[h|(\Delta^1 \times \Delta^{m-1})]{} & D \end{array}$$

are in bijection with (dotted) lifts in the adjoint diagram

$$\begin{array}{ccc} \Lambda^{m-1}_{m-1} & \longrightarrow & \mathrm{Fun}(\Delta^1, C) \\ \downarrow & \nearrow & \downarrow (t,p) \\ \Delta^{m-1} & \xrightarrow[\eta]{} & \mathrm{Fun}(\Delta^{\{1\}}, C) \times_{\mathrm{Fun}(\Delta^{\{1\}}, D)} \mathrm{Fun}(\Delta^1, D). \end{array}$$

Such a lift exists by [25, Lm. 6.1.1.1]. Consequently, a lift g' exists, and it specifies a family of maps

$$g'_N \colon \sigma(N) \longrightarrow C$$

for $N \in R(k)$ with $N > N_{k-1}$.

Now to obtain a (dotted) lift

$$\begin{array}{ccc} P_{N_{k-1}}(k) & \xrightarrow{g_{N_{k-1}}} & C \\ \downarrow & \overset{g_{N_{k-1}+1}}{\nearrow} & \downarrow p \\ P_{N_{k-1}+1}(k) & \xrightarrow[h|P_{N_{k-1}+1}(k)]{} & D, \end{array}$$

we must extend along

$$\sigma(N_{k-1}) \cap P_{N_{k-1}} \cong \Lambda^m_{\{m-1,m\}} \hookrightarrow \Delta^m \cong \sigma(N_{k-1}),$$

which we factor as the composite

$$\Lambda^m_{\{m-1,m\}} \hookrightarrow \Lambda^m_{\{m-1,m\}} \cup^{\Lambda^{\{0,\dots,m-1\}}_{m-1}} \Delta^{\{0,\dots,m-1\}} \cong \Lambda^m_{m-1} \hookrightarrow \Delta^m.$$

We extend across the first inclusion by using the restriction of the lift g' we have constructed, and then we extend across the inner horn $\Lambda^m_{m-1} \hookrightarrow \Delta^m$ using the fact that p is an inner fibration.

Now for any $N > N_{k-1}$, extend across P_{N+1} as follows: if $N \in R(k)$, extend using the chosen map g'_N, which since

$$\sigma(N) \cap P_N = (\sigma(N) \cap P_{N_{k-1}}) \cup \bigcup_{K \in R(k),\ K<N} (\sigma(N) \cap \sigma(K)),$$

is compatible with the map $P_N \longrightarrow C$ constructed so far. If $N \notin R(k)$, simply extend using the fact that $\sigma(N) \cap P_N \hookrightarrow \sigma(N)$ is an inner horn inclusion. At the end of this procedure, the desired extension

$$\overline{g} \colon P_{2^m} = \widetilde{\mathscr{O}}(\Delta^m)^{op} \longrightarrow C$$

is constructed, and it is ambigressive cartesian by construction. □

Now let us complete the proof of the theorem.

12.16. **Lemma.** *Suppose p satisfies conditions (12.2.1-3) and that $k = 0$. If the morphism $g(01) \twoheadrightarrow g(00)$ is p-cartesian and the morphism $g(01) \rightarrowtail g(11)$ is p-cocartesian, then there is an ambigressive cartesian (dotted) lift*

$$\begin{array}{ccc} \widetilde{\mathscr{O}}(\Lambda^m_k)^{op} & \xrightarrow{g} & C \\ \downarrow & \overset{\overline{g}}{\nearrow} & \downarrow p \\ \widetilde{\mathscr{O}}(\Delta^m)^{op} & \xrightarrow[h]{} & D \end{array}$$

Proof. Again let's treat the case $m = 2$ separately. In this case, since the morphism $g(0,1) \twoheadrightarrow g(0,0)$ is p-cartesian, we obtain a 2-simplex

$$\begin{array}{ccccc} & & g(0,1) & & \\ & \nearrow & & \searrow & \\ g(0,2) & & \twoheadrightarrow & & g(0,0). \end{array}$$

Now after filling inner horns, we choose a p-cocartesian edge $g(0,2) \rightarrowtail g(1,2)$ lying over $h(0,2) \rightarrowtail h(1,2)$, and then by filling the corresponding outer horns, we obtain a diagram

$$\begin{array}{ccccc} & & g(0,2) & & \\ & \swarrow & & \searrow & \\ g(0,1) & & & & g(0,2) \\ \swarrow \quad \searrow & & & & \swarrow \quad \searrow \\ g(0,0) \qquad & & g(1,1) & & \qquad g(2,2) \end{array}$$

It follows from conditions (12.2.1-2) that the morphisms are ingressive or egressive as marked and that the square is ambigressive cartesian.

For $m \geq 3$, we will once again proceed by induction on the filtration

$$\widetilde{\mathscr{O}}(\Lambda^m_k)^{op} = P_0(k) \subset \cdots \subset P_{2^m}(k) = \widetilde{\mathscr{O}}(\Delta^m)^{op}.$$

Given a lift

$$\begin{array}{ccc} \widetilde{\mathscr{O}}(\Lambda^m_k)^{op} & \xrightarrow{g} & C \\ \downarrow & \overset{g_N}{\nearrow} & \downarrow p \\ P_N(k) & \xrightarrow[h|P_N(k)]{} & D, \end{array}$$

we seek a (dotted) lift

$$\begin{array}{ccc} P_N(k) & \xrightarrow{g_N} & C \\ \downarrow & \overset{g_{N+1}}{\nearrow} & \downarrow p \\ P_{N+1}(k) & \xrightarrow[h|P_{N+1}(k)]{} & D. \end{array}$$

Once again, one really only has to tiptoe around the exceptional m-simplices.

To begin, we may easily extend g along the inclusion

$$\sigma(0) \cap P_0 \cong \Lambda^m_m \hookrightarrow \Delta^m \cong \sigma(0)$$

(the exceptional m-simplex of type (12.14.3)), since the edge $g|\Delta^{\{m-1,m\}}$ is p-cartesian.

Now for $0 < N < 2^m - 1$, we have two options for the inclusion

$$\sigma(N) \cap P_N \cong \Lambda^m_{E(N,0)} \hookrightarrow \Delta^m \cong \sigma(N):$$

either it is inner anodyne, in which case it is easy to extend along it, using the fact that p is an inner fibration, or else N is exceptional of type (12.14.4), and hence $N = N_t$ for some integer $0 < t < m$, and $E(N_t, 0) = \{0, m\}$.

To extend along the inclusion

$$\sigma(N_t) \cap P_{N_t} \cong \Lambda^m_{\{0,m\}} \hookrightarrow \Delta^m \cong \sigma(N_t),$$

we factor it as the composite

$$\Lambda^m_{\{0,m\}} \hookrightarrow \Lambda^m_{\{0,m\}} \cup^{\Lambda_0^{\{0,\dots,m-1\}}} \Delta^{\{0,\dots,m-1\}} \cong \Lambda^m_0 \hookrightarrow \Delta^m.$$

Extensions along each of these inclusions exists simply because the edge $g|\Delta^{\{0,1\}}$ is p-cocartesian.

At the end of this procedure, we are left with an extension $P_{2^m-1} \longrightarrow C$. To extend over $\sigma(2^m - 1)$ (the exceptional m-simplex of type (12.14.5)), it suffices just to note that, by assumption, $g|\Delta^{\{0,1\}}$ is p-cocartesian, so one may extend over the inclusion

$$\sigma(2^m - 1) \cap P_{2^m-1} \cong \Lambda^m_0 \hookrightarrow \Delta^m \cong \sigma(2^m - 1).$$

The result is the desired extension

$$\overline{g}\colon P_{2^m} = \widetilde{\mathscr{O}}(\Delta^m)^{op} \longrightarrow C,$$

which is ambigressive cartesian by construction. □

The proof of Th. 12.2 is complete.

13. The Burnside Waldhausen bicartesian fibration

Perhaps the most important Waldhausen bicartesian fibration is the one whose algebraic K-theory will be the spectral Burnside Mackey functor $\mathbf{S}_{(C,C_\dagger,C^\dagger)}$. To describe it, we need some preparatory material.

13.1. **Notation.** In this subsection, let us fix a disjunctive triple $(C, C_\dagger, C^\dagger)$.

13.2. **Definition.** Let us say a morphism $X \longrightarrow U$ of C is a ***summand inclusion*** if there exists a morphism $X' \longrightarrow U$ of C that, together with $X \longrightarrow U$, exhibits U as the coproduct $X \sqcup X'$.

Now if $i\colon X \hookrightarrow U$ is a summand inclusion, a ***complement*** of i is a summand inclusion $i'\colon X' \hookrightarrow U$ such that any square

$$\begin{array}{ccc} \varnothing & \hookrightarrow & X \\ \downarrow & & \downarrow i \\ X' & \underset{i'}{\hookrightarrow} & U \end{array}$$

in which $\varnothing$ is initial in C is a pushout square.

13.3. The compatibility of ingressive and egressive morphisms with coproducts implies that summand inclusions are necessarily ingressive and egressive. Note also that the pullback of a summand inclusion along a morphism that is both ingressive and egressive is again a summand inclusion. Furthermore, the pushout of a summand inclusion $i\colon X \hookrightarrow U$ along any map $f\colon X \longrightarrow Y$ exists and is again a summand inclusion. Finally, a complement for i is a complement for the pushout $j\colon Y \hookrightarrow V$ of i along f.

The following lemma will allow us to formulate definitions using complements, as long as we do not use any non-homotopy-invariant constructions.

13.4. **Lemma.** *Suppose $i\colon X \hookrightarrow U$ a summand inclusion. If $\mathrm{Compl}(i) \subset C_{/U}$ denotes the full subcategory spanned by the complements of i, then the Kan complex $\iota\mathrm{Compl}(i)$ is contractible.*

Proof. We show that the diagonal map $\iota\mathrm{Compl}(i) \longrightarrow \iota\mathrm{Compl}(i) \times \iota\mathrm{Compl}(i)$ is a weak equivalence. To this end, we observe that since C admits all ambigressive pullbacks, it follows that the full subcategory $\mathrm{Sum}(U) \subset C_{/U}$ spanned by the summand inclusions admits all finite products. Consequently, the diagonal functor $\mathrm{Sum}(U) \longrightarrow \mathrm{Sum}(U) \times \mathrm{Sum}(U)$ admits a right adjoint, which is given informally by the assignment

$$(X'_1 \hookrightarrow U,\ X'_2 \hookrightarrow U) \longmapsto (X'_1 \times_U X'_2 \hookrightarrow U).$$

Our claim is that this right adjoint restricts to a quasi-inverse

$$\iota\mathrm{Compl}(i) \times \iota\mathrm{Compl}(i) \longrightarrow \iota\mathrm{Compl}(i)$$

of the diagonal. For this, we must show that if

$$i'_1\colon X'_1 \hookrightarrow U \quad \text{and} \quad i'_2\colon X'_2 \hookrightarrow U$$

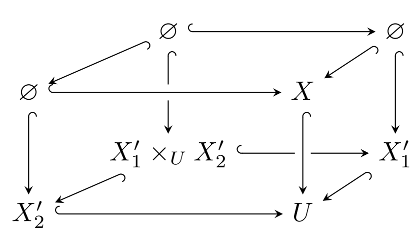
are complements of i, then the projection maps

$$X'_1 \times_U X'_2 \longrightarrow X'_1 \quad \text{and} \quad X'_1 \times_U X'_2 \longrightarrow X'_2$$

are equivalences, and the morphism $i'_{12}\colon X'_1 \times_U X'_2 \hookrightarrow U$ is a complement of i. Indeed, the universality of coproducts implies that the projection $X'_1 \times_U X'_2 \longrightarrow X'_1$ factors as

$$X'_1 \times_U X'_2 \xrightarrow{\sim} (X'_1 \times_U X'_2) \sqcup (X'_1 \times_U X) \simeq X'_1 \times_U (X'_2 \sqcup X) \simeq X'_1 \times_U U \simeq X'_1$$

(and similarly for the projection $X'_1 \times_U X'_2 \longrightarrow X'_2$). Now in the cube



every face is a pullback, and all faces but the top and bottom squares are pushouts, whence i'_{12} is a complement of i. □

13.5. **Definition.** We consider the fibration

$$p\colon \mathrm{Fun}(\Delta^2/\Delta^{\{0,2\}}, C) \cong \mathrm{Fun}(\Delta^2, C) \times_{\mathrm{Fun}(\Delta^{\{0,2\}},C)} C \longrightarrow C.$$

We may think of the objects of the ∞-category $\mathrm{Fun}(\Delta^2/\Delta^{\{0,2\}}, C)$ as retract diagrams

$$S_0 \longrightarrow S_1 \longrightarrow S_0;$$

the functor p is given by the assignment

$$[S_0 \longrightarrow S_1 \longrightarrow S_0] \longmapsto S_0.$$

We therefore denote by $C_{S_0/\ /S_0}$ the fiber of p over an object $S_0 \in C$.

We consider the full subcategory $\mathscr{R}(C) \subset \mathrm{Fun}(\Delta^2/\Delta^{\{0,2\}}, C)$ spanned by those objects S such that the morphism $S_0 \longrightarrow S_1$ is a summand inclusion. We endow $\mathscr{R}(C)$ with the structure of a pair in the following manner. A morphism $T \longrightarrow S$ will be declared ingressive just in case $T_0 \longrightarrow S_0$ is an equivalence, and $T_1 \longrightarrow S_1$ is a summand inclusion.

Now let $\mathscr{R}(C, C_\dagger, C^\dagger) \subset \mathscr{R}(C)$ be the full subcategory spanned by those objects $S\colon \Delta^2/\Delta^{\{0,2\}} \longrightarrow C$ such that for any complement $S_0' \hookrightarrow S_1$ of the summand inclusion $S_0 \hookrightarrow S_1$,

(13.5.1) the essentially unique morphism $S_0' \longrightarrow *$ to the terminal object of C is egressive, and

(13.5.2) the composite $S_0' \longrightarrow S_1 \longrightarrow S_0$ is ingressive.

We endow $\mathscr{R}(C, C_\dagger, C^\dagger)$ with the pair structure induced by $\mathscr{R}(C)$. We will abuse notation by denoting the restriction of the functor $p\colon \mathscr{R}(C) \longrightarrow C$ to the subcategory $\mathscr{R}(C, C_\dagger, C^\dagger) \subset \mathscr{R}(C)$ again by p.

We will now show that p is a Waldhausen bicartesian fibration. This claim follows from the following sequence of observations.

13.6**.** For any object S_0 of C, the fiber $\mathscr{R}(C)_{S_0}$ can be identified with the full subcategory of $C_{S_0/\ /S_0}$ spanned by those objects U such that $S \hookrightarrow U$ is a summand inclusion. A morphism $S_1 \longrightarrow S_1'$ of this ∞-category is ingressive just in case it is a summand inclusion. It is an easy consequence of the existence of finite coproducts and the compatibility of the triple structure with these coproducts that the full subcategory $\mathscr{R}(C, C_\dagger, C^\dagger)_{S_0} \subset \mathscr{R}(C)_{S_0}$ is a Waldhausen ∞-category.

13.7**.** For any ingressive morphism $f\colon S_0 \rightarrowtail T_0$ and for any object $S \in \mathscr{R}(C, C_\dagger, C^\dagger)$ over S_0, there exists a pushout diagram

$$\begin{array}{ccc} S_0 & \rightarrowtail & T_0 \\ \downarrow & & \downarrow \\ S_1 & \rightarrowtail & T_1 \\ \downarrow & & \downarrow \\ S_0 & \rightarrowtail & T_0, \end{array}$$

hence a p-cocartesian edge covering f. The compatibility of the triple structure with coproducts ensures that this defines a functor

$$f_!\colon \mathscr{R}(C, C_\dagger, C^\dagger)_{S_0} \longrightarrow \mathscr{R}(C, C_\dagger, C^\dagger)_{T_0}.$$

The functors $f_!$ are exact because they are all left adjoints, which preserve any colimits that exist.

13.8. Dually, for any egressive morphism $f\colon S_0 \twoheadrightarrow T_0$ and for any object $T \in \mathscr{R}(C, C_\dagger, C^\dagger)$ over T_0, there exists a pullback diagram

$$\begin{array}{ccc} S_0 & \twoheadrightarrow & T_0 \\ \downarrow & & \downarrow \\ S_1 & \twoheadrightarrow & T_1 \\ \downarrow & & \downarrow \\ S_0 & \twoheadrightarrow & T_0. \end{array}$$

We claim that the functor $f^\star\colon \mathscr{R}(C)_{T_0} \longrightarrow \mathscr{R}(C)_{S_0}$ is given informally by the assignment $T_1 \longmapsto T_1 \times_{T_0} S_0$. This follows from the fact that for any cofibration $T_0' \rightarrowtail T_0$ such that the morphism $T_0' \twoheadrightarrow *$ is egressive, the pullback $T_0' \times_{T_0} S_0 \rightarrowtail S_0$ is a cofibration and the morphism $T_0' \times_{T_0} S_0 \longrightarrow *$ is egressive. This follows from the fact that the pullback of an egressive map is egressive, and the pullback of an ingressive map along an egressive map is ingressive. The universality of finite coproducts in C ensures that the functors $f^\star$ preserve finite coproducts; in particular the functors $f^\star$ preserve summand inclusions and pushouts along summand inclusions.

13.9. Now suppose I a finite set, and suppose $\{X_i \mid i \in I\}$ a collection of objects of C indexed by the elements of I with coproduct X. We claim that the functor

$$C_{/X} \xrightarrow{\sim} \prod_{i\in I} C_{/X_i}$$

induced by the inclusions $X_i \hookrightarrow X$ induce an equivalence

$$\mathscr{R}(C, C_\dagger, C^\dagger)_X \xrightarrow{\sim} \prod_{i\in I} \mathscr{R}(C, C_\dagger, C^\dagger)_{X_i}.$$

One need only note that both this functor, which is given by pullbacks along summand inclusions (which are egressive), and its left adjoint, which is given by coproduct, preserve the desired subcategories and restrict to adjoint equivalences.

13.10. Finally, the base change condition for $\mathscr{R}(C, C_\dagger, C^\dagger)$ states that for any ambigressive pullback square

$$\begin{array}{ccc} S_0 & \overset{i}{\rightarrowtail} & S_0' \\ {\scriptstyle q}\downarrow & & \downarrow{\scriptstyle q'} \\ T_0 & \underset{j}{\rightarrowtail} & T_0', \end{array}$$

of C and for any object T_1' of C over T_0, the base change morphism

$$((T_0 \sqcup T_1') \times_{T_0} S_0) \cup^{S_0} S_0' \longrightarrow ((T_0 \sqcup T_1') \cup^{T_0} T_0') \times_{T_0'} S_0'$$

is an equivalence. This follows from the identifications

$$\begin{aligned}((T_0 \sqcup T_1') \times_{T_0} S_0) \cup^{S_0} S_0' &\simeq (S_0 \sqcup (T_1' \times_{T_0} S_0)) \cup^{S_0} S_0' \\ &\simeq S_0' \sqcup (T_1' \times_{T_0} S_0) \\ &\simeq S_0' \sqcup (T_1' \times_{T_0'} S_0') \\ &\simeq (T_0' \sqcup T_1') \times_{T_0'} S_0' \\ &\simeq ((T_0 \sqcup T_1') \cup^{T_0} T_0') \times_{T_0'} S_0',\end{aligned}$$

which all follow from the universality of finite coproducts in C and the equivalence $S_0 \simeq T_0 \times_{T_0'} S_0'$.

We thus conclude the following.

13.11. **Theorem.** *For any disjunctive triple $(C, C_\dagger, C^\dagger)$ that is either left or right complete, the functor*

$$p\colon \mathscr{R}(C, C_\dagger, C^\dagger) \longrightarrow C$$

is a Waldhausen bicartesian fibration over $(C, C_\dagger, C^\dagger)$.

Now let's unfurl this Waldhausen bicartesian fibration to obtain a Waldhausen cocartesian fibration

$$\Upsilon(p)\colon \Upsilon(\mathscr{R}(C, C_\dagger, C^\dagger)) \longrightarrow A^{eff}(C, C_\dagger, C^\dagger),$$

whence we obtain a Mackey functor

$$\mathscr{M}_p\colon A^{eff}(C, C_\dagger, C^\dagger) \longrightarrow \mathbf{Wald}_\infty.$$

Note that the assignment

$$[1 \twoheadleftarrow U \rightarrowtail X] \longmapsto [X \hookrightarrow X \sqcup U \longrightarrow X]$$

defines a functor

$$A^{eff}(C, C_\dagger, C^\dagger)_{1/} \longrightarrow \iota_{A^{eff}(C,C_\dagger,C^\dagger)}\mathscr{R}(C, C_\dagger, C^\dagger)$$

of left fibrations over $A^{eff}(C, C_\dagger, C^\dagger)$, and it follows from Lm. 13.4 that it is a fiberwise equivalence. Consequently, we deduce that the functor $\iota \circ \mathscr{M}_p$ is naturally equivalent to the functor represented by the terminal object 1.

Now, almost by definition, the Waldhausen ∞-category $\mathscr{M}_p(S) \simeq \mathscr{R}(C, C_\dagger, C^\dagger)_S$ is ι-split. We therefore conclude the following.

13.12. **Theorem.** *For any disjunctive triple $(C, C_\dagger, C^\dagger)$ that is either left or right complete, the functor*

$$\mathbf{K} \circ \mathscr{M}_p\colon A^{eff}(C, C_\dagger, C^\dagger) \longrightarrow \mathbf{Sp}$$

is the Burnside Mackey functor $\mathbf{S}_{(C,C_\dagger,C^\dagger)}$ — i.e., the Mackey functor represented by the terminal object $1 \in C$ (Df. 8.1).

Example A. Coherent n-topoi and the Segal–tom Dieck splitting

The similarities between the axioms for a disjunctive ∞-category and the Giraud axioms for n-topoi [25, Th. 6.1.0.6(3)] suggest a deep relationship between the two notions. Here, we briefly describe a way for higher topoi to give rise to a disjunctive ∞-category.

A.1. **Example.** Any subcategory of an n-topos ($1 \leq n \leq \infty$) that is stable under finite limits and finite coproducts is obviously disjunctive. All our examples in this paper are ultimately of this kind. In fact, one can show that every disjunctive ∞-category arises (possibly after a change of universe) in this manner. (If τ is a strongly inaccessible uncountable cardinal, then any τ-small disjunctive ∞-category C can be embedded in the full subcategory $\mathscr{X} \subset \mathrm{Fun}(C^{op}, \mathbf{Kan}(\tau))$ spanned by the functors that preserve products. This is an accessible localization of the ∞-category $\mathrm{Fun}(C^{op}, \mathbf{Kan}(\tau))$, and one can show that the localization functor $\mathrm{Fun}(C^{op}, \mathbf{Kan}(\tau)) \longrightarrow \mathscr{X}$ is left exact, whence $\mathscr{X}$ is an ∞-topos.)

A.2. **Example.** More particularly, the full subcategory $\mathscr{X}^{coh}$ of a coherent ∞-topos $\mathscr{X}$ spanned by the coherent objects [27, Df. 3.12] is thus a disjunctive ∞-category. Furthermore, for any natural number n, the full subcategory $\tau_{\leq n}\mathscr{X}^{coh}$ spanned by the n-truncated objects is a full subcategory of an $(n+1)$-topos that is closed under finite coproducts and finite limits; hence it too is a disjunctive ∞-category.

For $1 \leq n < \infty$, let us say that an object U of an n-topos $\mathscr{X}$ is ***coherent*** if for any n-localic ∞-topos $\mathscr{Y}$ and any equivalence $\phi\colon \mathscr{X} \xrightarrow{\sim} \tau_{\leq n-1}\mathscr{Y}$, the object $\phi(U)$ is coherent. If $\mathscr{Y}$ is coherent, then we will say that $\mathscr{X}$ is ***coherent***, and the full subcategory $\mathscr{X}^{coh} \subset \mathscr{X}$ by the coherent objects is a disjunctive ∞-category.

A.3. **Example.** In particular, the ∞-category $\mathbf{Kan}^{coh}$ of Kan simplicial sets all of whose homotopy groups are finite is a disjunctive ∞-category, and for any $n \geq 0$, the truncation $\tau_{\leq n}\mathbf{Kan}^{coh}$ (whose objects may be called ***finite*** n***-groupoids***) is a disjunctive ∞-category.

The effective Burnside ∞-category $A^{\mathit{eff}}(\tau_{\leq n}\mathbf{Kan}^{coh})$ is an $(n+1)$-category in the sense of [25, Df. 2.3.4.1]. The homotopy category of $A^{\mathit{eff}}(\tau_{\leq 1}\mathbf{Kan}^{coh}) = A^{\mathit{eff}}(\mathbf{F})$ (where $\mathbf{F}$ is the nerve of the ordinary category of finite sets) is the ordinary effective Burnside category for the trivial group.

The following proposition, whose proof we leave to the reader, can be summarized by saying that the ∞-category $A^{\mathit{eff}}(\mathbf{F})$ as the free ∞-category with direct sums generated by a single object (the terminal object 1 of $\mathbf{F}$).

A.4. **Proposition.** *For any ∞-category E that admits direct sums, evaluation at the terminal object* 1 *induces an equivalence of ∞-categories*

$$\mathbf{Mack}(\mathbf{F}, E) \xrightarrow{\sim} E.$$

Let us turn now to a general version of the Segal–tom Dieck splitting theorem.

A.5. **Notation.** To this end, note that if $\mathscr{X}$ is a coherent n-topos ($1 \leq n \leq \infty$), then there is a functor $\delta\colon \mathbf{F} \longrightarrow \mathscr{X}^{coh}$ informally given by the assignment

$$S \longmapsto S \otimes 1 \simeq \coprod_{s \in S} 1.$$

See [25, §4.4.4].

A.6. **Definition.** A coherent n-topos $\mathscr{X}$ will be said to be ***locally connected*** if the functor δ admits a left adjoint π.

The idea here is of course that for any coherent object X, the unit morphism $X \longrightarrow \delta\pi X$ will decompose X into finitely many summands, each of which will be "connected," in a unique manner. Indeed, for any object X, one may exhibit X as a canonical coproduct

$$X \simeq \coprod_{\alpha \in \pi X} (X \times_{\delta\pi X} \delta\{\alpha\}).$$

These objects $X \times_{\delta\pi X} \delta\{\alpha\}$ are now connected in the following sense.

A.7. **Definition.** Suppose $\mathscr{X}$ a coherent n-topos. A coherent object X of $\mathscr{X}$ will be said to be ***connected*** if the functor $\mathscr{X}^{coh} \longrightarrow \mathbf{Kan}$ it corepresents preserves finite coproducts. Equivalently, X is connected just in case πX is a one-point set. Denote by $\mathscr{X}^{conn} \subset \mathscr{X}^{coh}$ the full subcategory spanned by the connected objects.

A.8. **Warning.** It is not necessarily the case that the terminal object $*$ of a locally connected coherent n-topos $\mathscr{X}$ is connected. If it is, then $\mathscr{X}$ is said to be ***connected***, and in this case δ is fully faithful.

It turns out that the spectral Burnside ring of a locally connected coherent n-topos can be identified with a suspension spectrum.

A.9. **Theorem** (Segal–tom Dieck, [39])**.** *Suppose $\mathscr{X}$ a locally connected coherent n-topos. Then there is a natural equivalence*

$$\mathbf{S}_{\mathscr{X}^{coh}}(1) \simeq \Sigma^{\infty}_{+} \iota\mathscr{X}^{conn} \simeq \bigvee_{X} \Sigma^{\infty}_{+} B\,\mathrm{Aut}(X),$$

where the wedge is taken over all equivalence classes of connected objects X, and $\mathrm{Aut}(X)$ *denotes the space of auto-equivalences of X.*

Proof. It follows from Th. 13.12 that $\mathbf{S}_{\mathscr{X}^{coh}}(1)$ can be identified with the group completion of the object $\iota\mathscr{X}^{coh} \in \mathrm{CAlg}(\mathbf{Kan})$, where the commutative algebra structure is given by coproduct. It therefore suffices to show that $\iota\mathscr{X}^{coh}$ is the free commutative algebra generated by the space $\iota\mathscr{X}^{conn}$ in the sense of [31, Ex. 3.1.3.12].

For this, note that the (homotopy) fiber of the map $\iota(\pi)\colon \iota\mathscr{X}^{coh} \longrightarrow \iota N\mathbf{F}$ over a finite set I of cardinality n may be described as the space of pairs (X, f) consisting of an object $X \in \iota\mathscr{X}^{coh}$ and an isomorphism $\pi(X) \xrightarrow{\sim} I$, which can in turn be identified with the product $(\iota\mathscr{X}^{conn})^n$. We therefore obtain an identification

$$\mathrm{Sym}^n(\iota\mathscr{X}^{conn}) \simeq B\Sigma_n \times^h_{\iota N\mathbf{F}} \iota\mathscr{X}^{coh}.$$

Since one has $\iota N\mathbf{F} \simeq \coprod_{n \geq 0} B\Sigma_n$, we find that

$$\iota\mathscr{X}^{coh} \simeq \coprod_{n \geq 0} \mathrm{Sym}^n(\iota\mathscr{X}^{conn}).$$

The proof is thus complete by [31, Ex. 3.1.3.11]. □

Example B. Equivariant spectra for a profinite group

Certain topological groups give a subexample of Ex. A.

B.1. **Definition.** A topological group is ***coherent*** if for every open subgroup H of G, there exist only finitely many subsets of the form HgH for $g \in G$.

B.2. Suppose G a coherent topological group. Suppose B_G the classifying 1-topos of G; that is, B_G is the nerve of the ordinary category of sets equipped with a continuous action of G. Then B_G is the nerve of a coherent topos [17, §D3.4], and the full subcategory B_G^{fin} spanned by the coherent objects is a disjunctive ∞-category.

B.3. A pro-discrete group G is coherent just in case it is profinite. In this case, the coherent objects of B_G are simply those continuous G-sets with only finitely many orbits. Hence the full subcategory $B_G^{\mathit{fin}} \subset B_G$ spanned by finite G-sets with open stabilizers is a disjunctive ∞-category. The effective Burnside ∞-category of B_G^{fin} will be denoted, abusively, $A^{\mathit{eff}}(G)$.

B.4. For any finite group G, the ∞-category $A^{\mathit{eff}}(G)$ is in fact a 2-category whose homotopy category $hA^{\mathit{eff}}(G)$ is the ordinary effective Burnside category for G; the ordinary Burnside category for G is the local group completion (obtained by forming the Grothendieck group of each of the Hom-sets under direct sum).

B.5. **Notation.** When $C = NB_G^{\mathit{fin}}$ for some profinite group G and E is some additive ∞-category, we will write

$$\mathbf{Mack}_G(E) := \mathbf{Mack}(NB_G^{\mathit{fin}}, E).$$

B.6. **Example.** When G is finite and $E = N\mathbf{Ab}$ is the nerve of the ordinary category of abelian groups, the ∞-category $\mathrm{Fun}(A^{\mathit{eff}}(NB_G^{\mathit{fin}}), N\mathbf{Ab})$ is naturally equivalent to the nerve of the ordinary category of functors $\mathrm{Fun}(hA^{\mathit{eff}}(NB_G^{\mathit{fin}}), \mathbf{Ab})$. Using the fact that the homotopy category $hA^{\mathit{eff}}(NB_G^{\mathit{fin}})$ is the ordinary effective Burnside category (3.8), we conclude that the full subcategory $\mathbf{Mack}_G(N\mathbf{Ab})$ is equivalent to the full subcategory of $\mathrm{Fun}(hA^{\mathit{eff}}(NB_G^{\mathit{fin}}), \mathbf{Ab})$ spanned by Mackey functors in the classical sense.

When G is finite and $E = \mathbf{Sp}$ is the ∞-category of spectra, work of Guillou and May [12] show that this ∞-category is equivalent to the underlying ∞-category of the relative category of genuine G-spectra in the sense of Lewis–May–Steinberger [24], Mandell–May [32], and Hill–Hopkins–Ravenel [14, 16, 15]. For general profinite groups G, we call $\mathbf{Mack}_G(\mathbf{Sp})$ the ***∞-category of G-equivariant spectra***.

B.7. Suppose G a profinite group, and suppose H a closed normal subgroup of G. Then the natural functor $\varphi\colon G \longrightarrow G/H$ induces a morphism of topoi

$$\varphi^\star\colon B_{G/H} \rightleftarrows B_G\colon \varphi_\star.$$

Both functors preserve coherent objects, finite coproducts and pullbacks. Hence we obtain functors

$$\varphi^\star\colon NB_{G/H}^{\mathit{fin}} \longrightarrow NB_G^{\mathit{fin}} \quad \text{and} \quad \varphi_\star\colon NB_G^{\mathit{fin}} \longrightarrow NB_{G/H}^{\mathit{fin}}.$$

For any presentable additive ∞-category E, we obtain adjunctions

$$\varphi^\star_!\colon \mathbf{Mack}_{G/H}(E) \rightleftarrows \mathbf{Mack}_G(E)\colon \varphi^{\star\star}$$

and

$$\varphi_{\star!}\colon \mathbf{Mack}_G(E) \rightleftarrows \mathbf{Mack}_{G/H}(E)\colon \varphi_\star^\star.$$

We write $\Psi^H := \varphi^{\star\star}$ and $\Phi^H := \varphi_{\star!}$. When G is finite, one may use the equivalence of Guillou–May [12] to interpret Ψ^H and Φ^H as functors on the ∞-categories of G- and G/H-equivariant spectra. One may show that these functors agree (up to equivalence) with the *Lewis–May fixed points* Ψ^H and the *geometric fixed points* Φ^H constructed by Mandell–May [32].

For any profinite group G, the 1-topos NB_G^{fin} is locally connected (connected, in fact). This fact permits us to use our Segal–tom Dieck Theorem A.9 to compute the value of the Burnside spectral Mackey functor

$$\mathbf{S}_G := \mathbf{S}_{NB_G^{fin}}$$

on the terminal G-set $[G/G]$. Indeed, the connected objects of NB_G^{fin} are precisely the finite G-sets with open stabilizers that are transitive. Up to equivalence, these are classified by conjugacy classes of open subgroups of G. The space of autoequivalences of the transitive G-set $[G/H]$ is equivalent to the quotient $N_G H/H$, whence we obtain the traditional Segal–tom Dieck splitting [39], now for profinite groups:

B.8. **Proposition.** *For any profinite group G, one has*

$$\mathbf{S}_G([G/G]) \simeq \bigvee_H \Sigma^\infty_+ B(N_G H/H),$$

where the wedge is indexed by conjugacy classes of open subgroups $H \leq G$.

Example C. A-theory and upside-down A-theory of ∞-topoi

In this section, we introduce two dual disjunctive triple structures on an ∞-topos, where the ingressive or egressive morphisms are defined by means of a finiteness condition. We use these structures to construct both the A-theory and the V-theory of ∞-topoi together with all their functorialities.

To begin, if we consider an ∞-topos as a disjunctive ∞-category, then there is a natural Waldhausen bicartesian fibration that lies over it. Let us investigate this now.

The following is an easy analogue of [25, Lm. 6.1.1.1].

C.1. **Lemma.** *If C is an ∞-category that admits both pullbacks and pushouts, then the functor*

$$\mathrm{Fun}(\Delta^2, C) \longrightarrow \mathrm{Fun}(\Delta^{\{0,2\}}, C)$$

is a both a cartesian fibration and a cocartesian fibration.

C.2. **Notation.** For the remainder of this section, suppose $\mathscr{X}$ an ∞-topos. We consider the fibration

$$p\colon \mathrm{Fun}(\Delta^2/\Delta^{\{0,2\}}, \mathscr{X}) \cong \mathrm{Fun}(\Delta^2, \mathscr{X}) \times_{\mathrm{Fun}(\Delta^{\{0,2\}}, \mathscr{X})} \mathscr{X} \longrightarrow \mathscr{X},$$

which is both cartesian and cocartesian. We may think of the objects of the ∞-category $\mathrm{Fun}(\Delta^2/\Delta^{\{0,2\}}, \mathscr{X})$ as retract diagrams

$$X \longrightarrow X' \longrightarrow X;$$

the functor p is given by the assignment

$$[X \longrightarrow X' \longrightarrow X] \longmapsto X.$$

We therefore denote $\mathscr{X}_{X/\ /X}$ the fiber of p over an object X of $\mathscr{X}$. For any morphism $f\colon X \longrightarrow Y$, the corresponding functors

$$f_!\colon \mathscr{X}_{X/\ /X} \longrightarrow \mathscr{X}_{Y/\ /Y} \quad \text{and} \quad f^\star\colon \mathscr{X}_{Y/\ /Y} \longrightarrow \mathscr{X}_{X/\ /X}$$

are given informally by the assignments $X' \longmapsto Y \cup^X X'$ and $Y' \longmapsto Y' \times_Y X$.

C.3. **Proposition.** *Endow the ∞-category $\mathrm{Fun}(\Delta^2/\Delta^{\{0,2\}}, \mathscr{X})$ with the pair structure in which a morphism f is ingressive just in case $p(f)$ is an equivalence. Then $p\colon \mathrm{Fun}(\Delta^2/\Delta^{\{0,2\}}, \mathscr{X}) \longrightarrow \mathscr{X}$ is a Waldhausen bicartesian fibration.*

Proof. The only nontrivial points are the following. For any morphism $f\colon X \longrightarrow Y$, the functor $f^\star$ preserves pushout squares by the universality of colimits in $\mathscr{X}$. The admissibility of p also follows from the universality of colimits in $\mathscr{X}$. Finally, if I is a finite set and $\{X_i\}_{i\in I}$ a family of objects of $\mathscr{X}$ with coproduct X, then pullback along the various inclusions $X_i \hookrightarrow X$ defines an equivalence of ∞-categories

$$\mathscr{X}_{X/\ /X} \xrightarrow{\sim} \prod_{i\in I} \mathscr{X}_{X_i/\ /X_i}.$$ □

This Waldhausen bicartesian fibration is not so interesting from the point of view of algebraic K-theory, as each ∞-category $\mathscr{X}_{X/\ /X}$ has vanishing K-theory. To make it more interesting, we must restrict attention to objects with a finiteness condition. We thus turn to the study of finiteness conditions on objects of the ∞-topos $\mathscr{X}$. We begin with the following result.

C.4. **Proposition.** *Suppose $X \in \mathscr{X}$ an object. An object $X' \in \mathscr{X}_{/X}$ is compact if and only if it is compact as an object of $\mathscr{X}$.*

Proof. It is easy to see that if X' is compact in $\mathscr{X}$, then it is compact in $\mathscr{X}_{/X}$. Conversely, the forgetful functor $\mathscr{X}_{/X} \longrightarrow \mathscr{X}$ admits a right adjoint that, thanks to the universality of colimits, preserves colimits. It follows from [25, Pr. 5.5.7.2(1)] that if X' is compact as an object of $\mathscr{X}_{/X}$, then it is compact as an object of $\mathscr{X}$. □

The following is now immediate.

C.4.1. **Corollary.** *If the ∞-topos $\mathscr{X}$ is compactly generated, then for any object $X \in \mathscr{X}$, the ∞-topos $\mathscr{X}_{/X}$ is compactly generated as well.*

In the ∞-category of spaces, those maps whose fibers are (homotopy) retracts of finite CW complexes play a special role. In a more general ∞-topos, this role is played by the *relatively compact* morphisms, which we define now.

C.5. **Definition** (Lurie, [25, Df. 6.1.6.4]). A morphism $Y \longrightarrow X$ of $\mathscr{X}$ is said to be ***relatively compact*** just in case, for any compact object S of $\mathscr{X}$ and any morphism $\eta\colon S \longrightarrow X$ and any pullback square

$$\begin{array}{ccc} Y_\eta & \longrightarrow & Y \\ \downarrow & & \downarrow \\ S & \xrightarrow[\eta]{} & X, \end{array}$$

the object Y_η is compact.

C.6. **Proposition.** *Suppose $\mathscr{G} \subset \mathscr{X}$ a full subcategory whose objects are compact that generates $\mathscr{X}$ under colimits (so that $\mathscr{X}$ is compactly generated). Then a morphism $Y \longrightarrow X$ of $\mathscr{X}$ is relatively compact just in case, for any object $T \in \mathscr{G}$ and* *any morphism* $\xi\colon T \longrightarrow X$ *and any pullback square*

$$\begin{array}{ccc} Y_\xi & \longrightarrow & Y \\ \downarrow & & \downarrow \\ T & \underset{\xi}{\longrightarrow} & X, \end{array}$$

the object Y_ξ *is compact.*

Proof. To prove this claim, it suffices to show that if

(C.6.1) $S \in \mathscr{X}^\omega$,
(C.6.2) $Z \in \mathscr{X}$, and
(C.6.3) $Z \longrightarrow S$ is a morphism such that for any pullback square

$$\begin{array}{ccc} Z_\xi & \longrightarrow & Z \\ \downarrow & & \downarrow \\ T & \underset{\xi}{\longrightarrow} & S, \end{array}$$

of $\mathscr{X}$ in which $T \in \mathscr{G}$, the object Z_ξ is compact,

then the object Z is also compact. To see this, we first argue that $\mathscr{X}^\omega$ is generated under finite colimits and retracts by $\mathscr{G}$; indeed, if $\mathscr{X}^f \subset \mathscr{X}^\omega$ denotes the full subcategory generated by $\mathscr{G}$ under finite colimits, then [25, Pr. 5.3.5.11] implies that the colimit preserving functor $\mathrm{Ind}(\mathscr{X}^f) \longrightarrow \mathrm{Ind}(\mathscr{X}^\omega) = \mathscr{X}$ corresponding to the inclusion $\mathscr{X}^f \hookrightarrow \mathscr{X}^\omega$ is an equivalence, whence $\mathscr{X}^\omega$ is the idempotent completion of $\mathscr{X}^f$ thanks to [25, Pr. 5.5.7.8]. We therefore may write S as a retract of a finite colimit of objects of $\mathscr{G}$, and employing the universality of colimits, we obtain a presentation of Z as a retract of a finite colimit of compact objects. □

C.7. **Example.** In particular, we deduce that the ∞-category **Kan** admits a disjunctive triple structure in which every morphism is ingressive, and a morphism is egressive just in case its fibers are compact (or, in the parlance of [9, p. 3], *homotopy finitely dominated*).

C.8. **Proposition.** *If* $\mathscr{X}_{\mathrm{rc}} \subset \mathscr{X}$ *denotes the subcategory of relatively compact morphisms, then the triples* $(\mathscr{X}, \mathscr{X}, \mathscr{X}_{\mathrm{rc}})$ *and* $(\mathscr{X}, \mathscr{X}_{\mathrm{rc}}, \mathscr{X})$ *are disjunctive.*

Proof. It is obvious that relatively compact morphisms are closed under pullback. The universality of colimits and the fact that compact objects of $\mathscr{X}$ are closed under finite coproducts implies that the class of relatively compact morphisms is compatible with coproducts. The other axioms all follow directly from the universality of colimits and the disjointness of finite coproducts in $\mathscr{X}$. □

C.9. **Notation.** Now let us restrict the Waldhausen bicartesian fibration

$$p\colon \mathrm{Fun}(\Delta^2/\Delta^{\{0,2\}}, \mathscr{X}) \longrightarrow \mathscr{X}.$$

Let us write $\mathscr{I}(\mathscr{X})$ for the full subcategory of $\mathrm{Fun}(\Delta^2/\Delta^{\{0,2\}}, \mathscr{X})$ spanned by those retract diagrams

$$X \longrightarrow X' \longrightarrow X$$

such that the object $X' \in \mathscr{X}_{X/\ /X}$ is compact. Dually, let us write $\mathscr{J}(\mathscr{X})$ for the full subcategory of $\mathrm{Fun}(\Delta^2/\Delta^{\{0,2\}}, \mathscr{X})$ spanned by those retract diagrams

$$X \longrightarrow X' \longrightarrow X$$

such that the morphism $X' \longrightarrow X$ is relatively compact.

C.10. **Theorem.** *Assume that $\mathscr{X}$ is compactly generated, and assume that the terminal object $1 \in \mathscr{X}$ is compact. The functor p restricts to Waldhausen bicartesian fibrations*

$$p_{\mathscr{I}(\mathscr{X})} \colon \mathscr{I}(\mathscr{X}) \longrightarrow \mathscr{X}$$

over $(\mathscr{X}, \mathscr{X}, \mathscr{X}_{\mathrm{rc}})$ and

$$p_{\mathscr{J}(\mathscr{X})} \colon \mathscr{J}(\mathscr{X}) \longrightarrow \mathscr{X}$$

over $(\mathscr{X}, \mathscr{X}_{\mathrm{rc}}, \mathscr{X})$.

Proof. The only points left to be shown are the following for a morphism $f \colon X \longrightarrow Y$ of $\mathscr{X}$.

(A) If $X' \in \mathscr{X}_{X/\ /X}$ is compact, then $X' \cup^X Y \in \mathscr{X}_{Y/\ /Y}$ is also compact.
(B) If $Y' \longrightarrow Y$ is relatively compact, then the pullback $Y' \times_Y X \longrightarrow X$ is also relatively compact.
(C) If f is relatively compact and $Y' \in \mathscr{X}_{Y/\ /Y}$ is compact, then $Y' \times_Y X \in \mathscr{X}_{X/\ /X}$ is also compact.
(D) If f is relatively compact and $X' \longrightarrow X$ is relatively compact, then the pushout $X' \cup^X Y \longrightarrow Y$ is also relatively compact.

To prove (1), note that the functor $\mathscr{X}_{X/\ /X} \longrightarrow \mathscr{X}_{Y/\ /Y}$ given by the assignment $X' \longmapsto X' \cup^X Y$ can be identified with the tensor product

$$u \otimes \mathrm{id} \colon \mathscr{X}_{/X} \otimes \mathbf{Kan}_* \longrightarrow \mathscr{X}_{/Y} \otimes \mathbf{Kan}_*$$

of presentable ∞-categories (in the sense of [31, §6.3.1]) of the forgetful functor $u \colon \mathscr{X}_{/X} \longrightarrow \mathscr{X}_{/Y}$ with the identity functor [31, Pr. 6.3.2.11]. By Pr. C.4 and Cor. C.4.1, u is an ω-good functor between compactly generated ∞-categories in the sense of [31, Nt. 6.3.7.8]. Hence by [31, Lm. 6.3.7.11], $u \otimes \mathrm{id}$ is ω-good as well. In particular, it preserves compact objects.

Assertion (2) is clear.

To prove (3), note that the functor $v \colon \mathscr{X}_{/Y} \longrightarrow \mathscr{X}_{/X}$ given by the assignment $Y' \longmapsto Y' \times_Y X$ preserves colimits by the universality of colimits in $\mathscr{X}$, and it preserves compact objects thanks to Pr. C.4; we thus conclude that v is ω-good. Once again we may identify the functor $\mathscr{X}_{Y/\ /Y} \longrightarrow \mathscr{X}_{X/\ /X}$ given by the assignment $Y' \longmapsto Y' \times_Y X$ with $v \otimes \mathrm{id}$, and once again we may appeal to [31, Lm. 6.3.7.11] to conclude that $v \otimes \mathrm{id}$ is ω-good.

Finally, to prove (4), assume that $S \in \mathscr{X}$ is a compact object and $S \longrightarrow Y$ a morphism. The universality of colimits implies that

$$(X' \cup^X Y) \times_Y S \simeq (X' \times_Y S) \cup^{(X \times_Y S)} S.$$

Since both $X' \longrightarrow X$ and $X \longrightarrow Y$ are relatively compact, it follows that both $X' \times_Y S$ and $X \times_Y S$ are compact. Since compact objects are closed under finite colimits, it follows that $(X' \cup^X Y) \times_Y S$ is compact as well, and this completes the proof that $X' \cup^X Y \longrightarrow Y$ is relatively compact. □

C.10.1. **Corollary.** *Assume that $\mathscr{X}$ is compactly generated, and assume that the terminal object $1 \in \mathscr{X}$ is compact. The unfurlings*

$$\Upsilon(p_{\mathscr{I}(\mathscr{X})}) \longrightarrow A^{\mathrm{eff}}(\mathscr{X}, \mathscr{X}, \mathscr{X}_{\mathrm{rc}}) \quad \textit{and} \quad \Upsilon(p_{\mathscr{J}(\mathscr{X})}) \longrightarrow A^{\mathrm{eff}}(\mathscr{X}, \mathscr{X}_{\mathrm{rc}}, \mathscr{X})$$

classify Mackey functors

$$\mathscr{M}_{\mathscr{I}(\mathscr{X})} \colon A^{\mathrm{eff}}(\mathscr{X}, \mathscr{X}, \mathscr{X}_{\mathrm{rc}}) \longrightarrow \mathbf{Wald}_\infty$$

and

$$\mathscr{M}_{\mathscr{J}(\mathscr{X})} \colon A^{\mathrm{eff}}(\mathscr{X}, \mathscr{X}_{\mathrm{rc}}, \mathscr{X}) \longrightarrow \mathbf{Wald}_\infty.$$

C.11. **Notation.** Assume that $\mathscr{X}$ is compactly generated, and assume that the terminal object $1 \in \mathscr{X}$ is compact. Write $\mathbf{A}$ and $\mathbf{\forall}$ for the composite Mackey functors

$$\mathbf{A}_{\mathscr{X}} := \mathbf{K} \circ \mathscr{M}_{\mathscr{I}(\mathscr{X})} \quad \text{and} \quad \mathbf{\forall}_{\mathscr{X}} := \mathbf{K} \circ \mathscr{M}_{\mathscr{J}(\mathscr{X})}.$$

For any object $X \in \mathscr{X}$, the spectrum $\mathbf{A}_{\mathscr{X}}(X)$ is the algebraic K-theory of the full subcategory $\mathscr{I}(\mathscr{X})_X \subset \mathscr{X}_{X/\ /X}$ spanned by the compact objects, and $\mathbf{\forall}_{\mathscr{X}}(X)$ is the algebraic K-theory of the full subcategory $\mathscr{J}(\mathscr{X})_X \subset \mathscr{X}_{X/\ /X}$ spanned by those retract diagrams $X \longrightarrow X' \longrightarrow X$ such that $X' \longrightarrow X$ is relatively compact.

C.12**.** Assume that $\mathscr{X}$ is compactly generated, and assume that the terminal object $1 \in \mathscr{X}$ is compact. We have equivalences

$$\mathrm{Map}_{\mathbf{Mack}(\mathscr{X}, \mathscr{X}, \mathscr{X}_{\mathrm{rc}}; \mathbf{Sp})}(\mathbf{S}_{(\mathscr{X}, \mathscr{X}, \mathscr{X}_{\mathrm{rc}})}, \mathbf{A}_{\mathscr{X}}) \simeq \mathbf{A}_{\mathscr{X}}(1)$$

and

$$\mathrm{Map}_{\mathbf{Mack}(\mathscr{X}, \mathscr{X}_{\mathrm{rc}}, \mathscr{X}; \mathbf{Sp})}(\mathbf{S}_{(\mathscr{X}, \mathscr{X}_{\mathrm{rc}}, \mathscr{X})}, \mathbf{\forall}_{\mathscr{X}}) \simeq \mathbf{\forall}_{\mathscr{X}}(1),$$

where 1 denotes the terminal object of $\mathscr{X}$. The object $1 \sqcup 1 \in \mathscr{X}_{1/\ /1}$ lies in both $\mathscr{I}(\mathscr{X})_1$ and $\mathscr{J}(\mathscr{X})_1$, whence its classes in the corresponding K-theories specify morphisms of Mackey functors

$$\mathbf{S}_{(\mathscr{X}, \mathscr{X}, \mathscr{X}_{\mathrm{rc}})} \longrightarrow \mathbf{A}_{\mathscr{X}} \quad \text{and} \quad \mathbf{S}_{(\mathscr{X}, \mathscr{X}_{\mathrm{rc}}, \mathscr{X})} \longrightarrow \mathbf{\forall}_{\mathscr{X}}.$$

We thus obtain, for any object $X \in \mathscr{X}$, assembly morphisms

$$\mathbf{S}_{(\mathscr{X}, \mathscr{X}, \mathscr{X}_{\mathrm{rc}})}(X) \longrightarrow \mathbf{A}_{\mathscr{X}}(X) \quad \text{and} \quad \mathbf{S}_{(\mathscr{X}, \mathscr{X}_{\mathrm{rc}}, \mathscr{X})}(X) \longrightarrow \mathbf{\forall}_{\mathscr{X}}(X).$$

We in turn obtain, for any three objects $U, V, X \in \mathscr{X}$ such that $U \longrightarrow 1$ is relatively compact, assembly morphisms

$$\Sigma^\infty_+ \mathrm{Map}_{\mathscr{X}}(U, X) \longrightarrow \mathbf{A}_{\mathscr{X}}(X) \quad \text{and} \quad \Sigma^\infty_+ \mathrm{Map}_{\mathscr{X}_{\mathrm{rc}}}(V, X) \longrightarrow \mathbf{\forall}_{\mathscr{X}}(X).$$

As in Df. 8.3, we obtain, for any object $X \in \mathscr{X}$, morphisms of Mackey functors

$$\mathbf{S}^X_{(\mathscr{X}, \mathscr{X}, \mathscr{X}_{\mathrm{rc}})} \longrightarrow F(\mathbf{A}_{\mathscr{X}}(X), \mathbf{A}_{\mathscr{X}}) \quad \text{and} \quad \mathbf{S}^X_{(\mathscr{X}, \mathscr{X}_{\mathrm{rc}}, \mathscr{X})} \longrightarrow F(\mathbf{\forall}_{\mathscr{X}}(X), \mathbf{\forall}_{\mathscr{X}}),$$

which induce, for any object $Y \in \mathscr{X}$, assembly morphisms

$$\mathbf{S}^X_{(\mathscr{X}, \mathscr{X}, \mathscr{X}_{\mathrm{rc}})}(Y) \wedge \mathbf{A}_{\mathscr{X}}(X) \longrightarrow \mathbf{A}_{\mathscr{X}}(Y)$$

and

$$\mathbf{S}^X_{(\mathscr{X}, \mathscr{X}_{\mathrm{rc}}, \mathscr{X})}(Y) \wedge \mathbf{\forall}_{\mathscr{X}}(X) \longrightarrow \mathbf{\forall}_{\mathscr{X}}(Y),$$

We in turn obtain, for any objects $U, V \in \mathscr{X}$ such that $U \longrightarrow 1$ is relatively compact, assembly morphisms

$$\Sigma^\infty_+ \mathrm{Map}_{\mathscr{X}}(U, X) \longrightarrow F(\mathbf{\forall}_{\mathscr{X}}(X), \mathbf{\forall}_{\mathscr{X}}(1))$$

and

$$\Sigma^\infty_+ \mathrm{Map}_{\mathscr{X}_{\mathrm{rc}}}(V, X) \longrightarrow F(\mathbf{A}_{\mathscr{X}}(X), \mathbf{A}_{\mathscr{X}}(1)).$$

C.13. **Example.** If $\mathscr{X} = \mathbf{Kan}$, then the functors $\mathbf{A}$ and $\mathbf{V}$ are fully functorial version of A-theory and V-theory as considered by Waldhausen in [40, §2.1] (modulo the small point that here we deal with finitely dominated spaces in place of finite spaces). The assembly morphisms above described above are

$$\Sigma^\infty_+ \operatorname{Map}(U, X) \longrightarrow \mathbf{A}(X) \quad \text{and} \quad \Sigma^\infty_+ \operatorname{Map}_{\mathrm{rc}}(V, X) \longrightarrow \mathbf{V}(X),$$

any three objects $U, V, X \in \mathscr{X}$ such that $U \longrightarrow *$ is relatively compact, where $\operatorname{Map}_{\mathrm{rc}}(V, X) \subset \operatorname{Map}(V, X)$ is the union of the connected components corresponding to maps $V \longrightarrow X$ with finitely dominated (homotopy) fibers. When $U = *$, the first of these morphisms is the usual assembly morphism $\Sigma^\infty_+ X \longrightarrow \mathbf{A}(X)$. Dually, we also have co-assembly morphisms

$$\Sigma^\infty_+ \operatorname{Map}(U, X) \longrightarrow F(\mathbf{V}(X), \mathbf{A}(*))$$

and

$$\Sigma^\infty_+ \operatorname{Map}_{\mathrm{rc}}(V, X) \longrightarrow F(\mathbf{A}(X), \mathbf{A}(*)).$$

(Observe that $\mathbf{A}(*) \simeq \mathbf{V}(*)$.) When $U = *$, the first of these morphisms seems to have been studied independently by Cary Malkiewich. When composed with the morphism induced by the trace

$$\mathbf{A}(*) \simeq \mathbf{K}(\mathbf{S}) \longrightarrow \mathrm{THH}(\mathbf{S}) \simeq \mathbf{S},$$

we obtain morphisms

$$\Sigma^\infty_+ \operatorname{Map}(U, X) \longrightarrow D\mathbf{V}(X) \quad \text{and} \quad \Sigma^\infty_+ \operatorname{Map}_{\mathrm{rc}}(V, X) \longrightarrow D\mathbf{A}(X).$$

Example D. Algebraic K-theory of derived stacks

We turn to a more geometric setting. Over suitable schemes, complexes of quasicoherent sheaves admit both a pushforward and pullback functor. The pullback carries perfect complexes to perfect complexes, but the pushforward does not, unless some heavy constraints are placed on the morphisms of schemes involved. In this subsection, we discuss such restrictions for a very general class of derived stacks.

There are two classes of examples in which we will be interested: *(i)* spectral Deligne–Mumford stacks and *(ii)* arbitrary sheaves of spaces for the flat site. In each case we will construct algebraic K-theory as a spectral Mackey functor relative to certain disjunctive triple structures.

D.1**.** For simplicity, in this section we work *absolutely*, i.e., over the sphere spectrum. Nothing here uses that fact in a nontrivial way, and all the results of this section can obviously be adapted to work over more general bases.

D.2. **Notation.** We consider the ∞-category $\mathbf{CAlg}^{\mathrm{cn}}$ of connective E_∞ rings and the huge ∞-topos

$$\mathbf{Shv}_{\mathrm{flat}} \subset \operatorname{Fun}(\mathbf{CAlg}^{\mathrm{cn}}, \mathbf{Kan}(\kappa_1))$$

of large sheaves on $\mathbf{CAlg}^{\mathrm{cn},op}$ for the flat topology [27, Pr. 5.4].

Let us begin by identifying two sources of disjunctive triples within the ∞-category $\mathbf{Shv}_{\mathrm{flat}}$. Since our aim is to study categories of modules that are contravariantly functorial in all morphisms but only covariantly functorial in certain classes of morphisms, these disjunctive triples will have the property that every morphism will be egressive, but the ingressives will be heavily restricted.

D.3. **Notation.** The full subcategory $\mathbf{DM} \subset \mathbf{Shv}_{\mathrm{flat}}$ spanned by those sheaves that are representable by spectral Deligne–Mumford stacks is closed under finite coproducts and pullbacks, whence it is a disjunctive ∞-category.

For any class $\mathscr{P}$ of morphisms of $\mathbf{DM}$ that is stable under pullback and compatible with coproducts in the sense of (5.2.4), one obtains a disjunctive triple

$$(\mathbf{DM}, \mathbf{DM}_{\mathscr{P}}, \mathbf{DM}),$$

where $\mathbf{DM}_{\mathscr{P}} \subset \mathbf{DM}$ is the subcategory that contains all the objects, in which the morphisms lie in $\mathscr{P}$.

D.4. **Notation.** Alternately, one may opt to keep all the objects of $\mathbf{Shv}_{\mathrm{flat}}$. Then for any class $\mathscr{P}$ of morphisms of $\mathbf{Shv}_{\mathrm{flat}}$ that is stable under pullback and compatible with coproducts in the sense of (5.2.4), one obtains a disjunctive triple

$$(\mathbf{Shv}_{\mathrm{flat}}, \mathbf{Shv}_{\mathrm{flat},\mathscr{P}}, \mathbf{Shv}_{\mathrm{flat}}),$$

where $\mathbf{Shv}_{\mathrm{flat},\mathscr{P}} \subset \mathbf{Shv}_{\mathrm{flat}}$ is the subcategory that contains all the objects, in which the morphisms lie in $\mathscr{P}$.

Our ultimate interest will be in the study of perfect modules over these sorts of objects, but let us first consider the larger ∞-category of quasicoherent modules.

D.5. **Notation.** We let

$$\begin{array}{ccc} \mathbf{Mod} & \longrightarrow & \mathbf{QCoh} \\ {\scriptstyle q}\downarrow & & \downarrow{\scriptstyle p} \\ \mathbf{CAlg}^{\mathrm{cn}} & \hookrightarrow & \mathbf{Shv}^{op}_{\mathrm{flat}} \end{array}$$

be a pullback square in which q is the cocartesian fibration of [31, Df. 4.4.1.1], and p is a cocartesian fibration classified by the right Kan extension of the functor that classifies q. The objects of $\mathbf{QCoh}$ can be thought of as pairs (X, M) consisting of a sheaf $X : \mathbf{CAlg}^{\mathrm{cn}} \longrightarrow \mathbf{Kan}(\kappa_1)$ for the flat topology and a quasicoherent module M over X.

D.6**.** Let us note that by [28, Pr. 2.7.17(1)], the fibers of p are all stable ∞-categories. Furthermore, since the functor $\mathbf{Shv}^{op}_{\mathrm{flat}} \longrightarrow \mathbf{Cat}_\infty(\kappa_1)$ that classifies p preserves limits [28, Pr. 2.7.14], it follows that for any finite set I and any collection $\{X_i \mid i \in I\}$ of sheaves, the natural functor

$$\mathbf{QCoh}_{\coprod_{i\in I} X_i} \longrightarrow \prod_{i \in I} \mathbf{QCoh}_{X_i}$$

is an equivalence.

D.7. **Warning.** Note that p is not a cartesian fibration. In general, the functor

$$f^\star : \mathbf{QCoh}_Y \longrightarrow \mathbf{QCoh}_X$$

induced by a natural transformation $f : X \longrightarrow Y$ will preserve all small colimits [28, Pr. 2.7.17(2)], but the ∞-categories may not be presentable unless one knows that X and Y are in some sense "small."

This smallness is ensured if, for example, X and Y are represented by spectral Deligne–Mumford stacks ([28, Prs. 2.3.13 and 2.7.18]). We therefore conclude the following.

D.8. **Lemma.** *The pulled back functor*

$$\mathbf{QCoh} \times_{\mathbf{Shv}^{op}_{\mathrm{flat}}} \mathbf{DM}^{op} \longrightarrow \mathbf{DM}^{op}$$

is both a cocartesian fibration and a cartesian fibration.

D.9. **Notation.** In the ∞-category $\mathbf{DM}$, consider the class $\mathscr{RS}$ of ***relatively scalloped*** morphisms in the sense of [28, Df. 2.5.10]. Then since relatively scalloped morphisms are stable under pullback and compatible with coproducts in the sense of (5.2.4), we obtain a disjunctive triple

$$(\mathbf{DM}, \mathbf{DM}_{\mathscr{RS}}, \mathbf{DM}).$$

D.10. **Proposition.** *The functor*

$$\mathbf{QCoh}^{op} \times_{\mathbf{Shv}_{\mathrm{flat}}} \mathbf{DM} \longrightarrow \mathbf{DM}$$

is a Waldhausen bicartesian fibration for the left complete disjunctive triple

$$(\mathbf{DM}, \mathbf{DM}_{\mathscr{RS}}, \mathbf{DM}).$$

Proof. By [28, Pr. 2.5.14], the relevant base change functors are all equivalences. □

D.11. **Notation.** In the bigger ∞-category of all flat sheaves, we consider the class $\mathscr{QA}$ in $\mathbf{Shv}_{\mathrm{flat}}$ of ***quasi-affine representable*** morphisms — that is, those morphisms $X \longrightarrow Y$ such that for any connective E_∞ ring R and any R-point $\eta\colon \operatorname{Spec} R \longrightarrow Y$, the pullback $X \times_Y \operatorname{Spec} R$ is representable by a spectral Deligne–Mumford stack X_η, and the map $X_\eta \longrightarrow \operatorname{Spec} R$ is quasi-affine [28, Df. 3.1.24]. Then since quasi-affine representable morphisms are stable under pullback and compatible with coproducts in the sense of (5.2.4), we have a disjunctive triple

$$(\mathbf{Shv}_{\mathrm{flat}}, \mathbf{Shv}_{\mathrm{flat},\mathscr{QA}}, \mathbf{Shv}_{\mathrm{flat}}).$$

The following is immediate from [28, Pr. 3.2.5].

D.12. **Lemma.** *The pulled back functor*

$$\mathbf{QCoh} \times_{\mathbf{Shv}^{op}_{\mathrm{flat}}} \mathbf{Shv}^{op}_{\mathrm{flat},\mathscr{QA}} \longrightarrow \mathbf{Shv}^{op}_{\mathrm{flat},\mathscr{QA}}$$

is both a cocartesian fibration and a cartesian fibration.

Furthermore, we deduce from [28, Cor. 3.2.6(2)] that the relevant base change functors are all equivalences, whence we conclude the following.

D.13. **Proposition.** *The functor*

$$p\colon \mathbf{QCoh}^{op} \longrightarrow \mathbf{Shv}_{\mathrm{flat}}$$

is a Waldhausen bicartesian fibration for the left complete disjunctive triple

$$(\mathbf{Shv}_{\mathrm{flat}}, \mathbf{Shv}_{\mathrm{flat},\mathscr{QA}}, \mathbf{Shv}_{\mathrm{flat}}).$$

D.14. **Notation.** Now denote by $\mathbf{Perf} \subset \mathbf{QCoh}$ the full subcategory spanned by those pairs (X, M) in which M is a perfect quasicoherent module on X — i.e., a strongly dualizable object of the symmetric monoidal ∞-category $\mathbf{QCoh}_X$. Endow $\mathbf{Perf}^{op}$ with its fiberwise maximal pair structure, so that

$$\mathbf{Perf}^{\dagger} := \mathbf{Perf} \times_{\mathbf{Shv}^{op}_{\mathrm{flat}}} \iota\mathbf{Shv}^{op}_{\mathrm{flat}}.$$

Note that the restricted functor

$$\mathbf{Perf}^{op} \longrightarrow \mathbf{Shv}_{\mathrm{flat}}$$

remains a Waldhausen cartesian fibration, since pullbacks are symmetric monoidal.

We now wish to shrink our classes of ingressives on $\mathbf{DM}$ and $\mathbf{Shv}_{\mathrm{flat}}$ to ensure that perfect modules define a supported Waldhausen bicartesian fibration. For this, it's enough to find a class of morphisms such that the pushforward preserves perfection.

D.15. **Definition.** Suppose $f\colon X \longrightarrow Y$ a morphism of $\mathbf{Shv}_{\mathrm{flat}}$ such that the functor $f^{\star}\colon \mathbf{QCoh}_Y \longrightarrow \mathbf{QCoh}_X$ admits a right adjoint $f_{\star}$. Call f ***perfect*** if $f_{\star}\colon \mathbf{QCoh}_X \longrightarrow \mathbf{QCoh}_Y$ carries perfect objects [28, Df. 2.7.21] to perfect objects.

Between spectral Deligne–Mumford stacks, Lurie identifies an important class of perfect morphisms.

D.16. **Proposition** (Lurie, [30, Pr. 3.3.20])**.** *If a morphism $f\colon X \longrightarrow Y$ of spectral Deligne–Mumford stacks is strongly proper* [30, Df. 3.1.1]*, of finite Tor-amplitude* [30, Df. 3.3.9]*, and locally almost of finite presentation* [26, Df. 8.16]*, then it is perfect.*

D.17. **Notation.** Denote by $\mathscr{FP}$ the class of strongly proper morphisms of finite Tor-amplitude [30, Df. 3.3.9] and locally almost of finite presentation. To see that the class $\mathscr{FP}$ is stable under pullbacks, combine [30, Rk. 3.1.5 and Pr. 3.3.16] and [26, Pr. 8.25]. It is easy to see that this class is compatible with coproducts in the sense of (5.2.4).

D.18. **Proposition.** *The functor*

$$p_{\mathbf{DM}}\colon \mathbf{Perf}^{op} \times_{\mathbf{Shv}_{\mathrm{flat}}} \mathbf{DM} \longrightarrow \mathbf{DM}$$

is a Waldhausen bicartesian fibration for the left complete disjunctive triple

$$(\mathbf{DM}, \mathbf{DM}_{\mathscr{FP}}, \mathbf{DM}).$$

D.18.1. **Corollary.** *The unfurling*

$$\Upsilon(p_{\mathbf{DM}}) \longrightarrow A^{\mathit{eff}}(\mathbf{DM}, \mathbf{DM}_{\mathscr{FP}}, \mathbf{DM})$$

is classified by a Mackey functor

$$\mathscr{M}_{\mathbf{DM}}\colon A^{\mathit{eff}}(\mathbf{DM}, \mathbf{DM}_{\mathscr{FP}}, \mathbf{DM}) \longrightarrow \mathbf{Wald}_{\infty}.$$

D.19. **Notation.** As a result, we obtain a Mackey functor

$$\mathbf{K} \circ \mathscr{M}_{\mathbf{DM}}\colon A^{\mathit{eff}}(\mathbf{DM}, \mathbf{DM}_{\mathscr{FP}}, \mathbf{DM}) \longrightarrow \mathbf{Sp}.$$

The algebraic K-theory of any Deligne–Mumford stack is an E_∞ ring spectrum, whence it has a canonical K-theory class, given by the unit. Correspondingly, we obtain a morphism of Mackey functors

$$\mathbf{S}_{(\mathbf{DM}, \mathbf{DM}_{\mathscr{FP}}, \mathbf{DM})} \longrightarrow \mathbf{K} \circ \mathscr{M}_{\mathbf{DM}}.$$

We thus obtain, for any Deligne–Mumford stacks U and X, an assembly morphism

$$\Sigma^{\infty}_{+} \operatorname{Mor}_{\mathscr{FP}}(U, X) \longrightarrow \mathbf{K}(X),$$

where $\operatorname{Mor}_{\mathscr{FP}}$ is the space of strongly proper morphisms of finite Tor-amplitude and locally almost of finite presentation.

As in Df. 8.3, we obtain a morphism of spectral Mackey functors

$$\mathbf{S}^{X}_{(\mathbf{DM}, \mathbf{DM}_{\mathscr{FP}}, \mathbf{DM})} \longrightarrow F(\mathbf{K}(X), \mathbf{K} \circ \mathscr{M}_{\mathbf{DM}}),$$

which induces assembly morphisms

$$\mathbf{S}^{X}_{(\mathbf{DM}, \mathbf{DM}_{\mathscr{FP}}, \mathbf{DM})}(Y) \wedge \mathbf{K}(X) \longrightarrow \mathbf{K}(Y).$$

We in turn obtain, for any spectral Deligne–Mumford stack U such that the morphism $U \longrightarrow \mathrm{Spec}^{\text{ét}}(\mathbf{S})$ is strongly proper, of finite Tor-amplitude, and locally almost of finite presentation, an assembly morphism

$$\Sigma^\infty_+ \operatorname{Map}(U, X) \longrightarrow F(\mathbf{K}(X), \mathbf{K}(\mathbf{S})).$$

When composed with the morphism induced by the trace

$$\mathbf{K}(\mathbf{S}) \longrightarrow \mathrm{THH}(\mathbf{S}) \simeq \mathbf{S},$$

we obtain a morphism

$$\Sigma^\infty_+ \operatorname{Map}(U, X) \longrightarrow D\mathbf{K}(X).$$

Now among the more general class of flat sheaves, let us characterize perfect morphisms that are also quasi-affine representable.

D.20. **Proposition.** *The following are equivalent for a quasi-affine representable morphism $f \colon X \longrightarrow Y$ of $\mathbf{Shv}_{\mathrm{flat}}$.*

(D.20.1) The morphism f is perfect.

(D.20.2) The quasicoherent module $f_\star \mathscr{O}_X$ is perfect.

Proof. That the first condition implies the second is obvious. To prove the converse, let us first reduce to the case where Y is affine. Indeed, for any quasicoherent module M over X, the quasicoherent module $f_\star M$ is perfect just in case, for any point $\eta \colon \operatorname{Spec} R \longrightarrow Y$, the R-module $\eta^\star f_\star M$ is perfect. Now consider the pullback

$$\begin{array}{ccc} X_\eta & \xrightarrow{f'} & \operatorname{Spec} R \\ {\scriptstyle\varepsilon}\downarrow & & \downarrow{\scriptstyle\eta} \\ X & \xrightarrow[f]{} & Y. \end{array}$$

One now has $\eta^\star f_\star M \simeq f'_\star \varepsilon^\star M$ [28, Cor. 3.2.6(2)], and if M is perfect, so is $\varepsilon^\star M$.

So we now assume that $Y = \operatorname{Spec} R$. Now let $A := f_\star \mathscr{O}_X$, an R-module. In light of [28, Pr. 3.2.5], we obtain an equivalence $\mathbf{QCoh}_X \simeq \mathbf{Mod}_A$, under which the functor $f_\star$ can be identified with the forgetful functor

$$U \colon \mathbf{Mod}_A \longrightarrow \mathbf{Mod}_R.$$

Now $U^{-1}(\mathbf{Perf}_R)$ is a stable subcategory that is closed under retracts, and by assumption it contains A. Hence $\mathbf{Perf}_A \subset U^{-1}(\mathbf{Perf}_R)$. ☐

D.20.1. **Corollary.** *The collection $\mathscr{Q}\mathscr{P}$ of quasi-affine representable and perfect morphisms of $\mathbf{Shv}_{\mathrm{flat}}$ is stable under pullback.*

Proof. Suppose

$$\begin{array}{ccc} X' & \xrightarrow{f'} & Y' \\ {\scriptstyle\alpha}\downarrow & & \downarrow{\scriptstyle\beta} \\ X & \xrightarrow[f]{} & Y \end{array}$$

a pullback square in $\mathbf{Shv}_{\mathrm{flat}}$, and suppose f quasi-affine representable and perfect. Then the quasicoherent module

$$f'_\star \mathscr{O}_{X'} \simeq f'_\star \alpha^\star \mathscr{O}_X \simeq \beta^\star f_\star \mathscr{O}_X$$

is perfect as well. ☐

It is a straightforward matter to see that $\mathscr{Q}\mathscr{P}$ is compatible with coproducts in the sense of (5.2.4). We thus conclude the following.

D.21. **Proposition.** *The functor*

$$\mathbf{Perf}^{op} \longrightarrow \mathbf{Shv}_{\mathrm{flat}}$$

is a Waldhausen bicartesian fibration for the left complete disjunctive triple

$$(\mathbf{Shv}_{\mathrm{flat}}, \mathbf{Shv}_{\mathrm{flat},\mathscr{Q}\mathscr{P}}, \mathbf{Shv}_{\mathrm{flat}}).$$

D.21.1. **Corollary.** *The unfurling*

$$\Upsilon(p_{\mathbf{Shv}_{\mathrm{flat}}}) \longrightarrow A^{\mathit{eff}}(\mathbf{Shv}_{\mathrm{flat}}, \mathbf{Shv}_{\mathrm{flat},\mathscr{Q}\mathscr{P}}, \mathbf{Shv}_{\mathrm{flat}})$$

is classified by a Mackey functor

$$\mathscr{M}_{\mathbf{Shv}_{\mathrm{flat}}}\colon A^{\mathit{eff}}(\mathbf{Shv}_{\mathrm{flat}}, \mathbf{Shv}_{\mathrm{flat},\mathscr{Q}\mathscr{P}}, \mathbf{Shv}_{\mathrm{flat}}) \longrightarrow \mathbf{Wald}_{\infty}.$$

D.22. **Notation.** As a result, we obtain a Mackey functor

$$\mathbf{K}\circ\mathscr{M}_{\mathbf{Shv}_{\mathrm{flat}}}\colon A^{\mathit{eff}}(\mathbf{Shv}_{\mathrm{flat}}, \mathbf{Shv}_{\mathrm{flat},\mathscr{Q}\mathscr{P}}, \mathbf{Shv}_{\mathrm{flat}}) \longrightarrow \mathbf{Sp}.$$

The algebraic K-theory of any flat sheaf is an E_∞ ring spectrum, whence it has a canonical K-theory class, given by the unit. Correspondingly, we obtain a morphism of Mackey functors

$$\mathbf{S}_{(\mathbf{Shv}_{\mathrm{flat}}, \mathbf{Shv}_{\mathrm{flat},\mathscr{Q}\mathscr{P}}, \mathbf{Shv}_{\mathrm{flat}})} \longrightarrow \mathbf{K}\circ\mathscr{M}_{\mathbf{Shv}_{\mathrm{flat}}}.$$

We thus obtain, for any flat sheaves U and X, an assembly morphism

$$\Sigma^\infty_+ \mathrm{Mor}_{\mathscr{Q}\mathscr{P}}(U,X) \longrightarrow \mathbf{K}(X),$$

where $\mathrm{Mor}_{\mathscr{Q}\mathscr{P}}$ is the space of quasi-affine representable and perfect morphisms.

Dually, as in Df. 8.3, we obtain a morphism of Mackey functors

$$\mathbf{S}^X_{(\mathbf{Shv}_{\mathrm{flat}}, \mathbf{Shv}_{\mathrm{flat},\mathscr{Q}\mathscr{P}}, \mathbf{Shv}_{\mathrm{flat}})} \longrightarrow F(\mathbf{K}(X), \mathbf{K}\circ\mathscr{M}_{\mathbf{Shv}_{\mathrm{flat}}}),$$

which induces assembly morphisms

$$\mathbf{S}^X_{(\mathbf{Shv}_{\mathrm{flat}}, \mathbf{Shv}_{\mathrm{flat},\mathscr{Q}\mathscr{P}}, \mathbf{Shv}_{\mathrm{flat}})}(Y)\wedge\mathbf{K}(X) \longrightarrow \mathbf{K}(Y)$$

for any flat sheaf Y. We in turn obtain, for any flat sheaf U such that $U \longrightarrow \mathrm{Spec}^{\mathrm{f}}(\mathbf{S})$ is quasiaffine representable and perfect, an assembly morphism

$$\Sigma^\infty_+ \mathrm{Map}(U,X) \longrightarrow F(\mathbf{K}(X), \mathbf{K}(\mathbf{S})).$$

When composed with the morphism induced by the trace

$$\mathbf{A}(*) \simeq \mathbf{K}(\mathbf{S}) \longrightarrow \mathrm{THH}(\mathbf{S}) \simeq \mathbf{S},$$

we obtain a morphism

$$\Sigma^\infty_+ \mathrm{Map}(U,X) \longrightarrow D\mathbf{K}(X).$$

Finally, let us restrict Ex. D to relate it to Ex. B.

D.23. **Notation.** Suppose X a spectral Deligne–Mumford stack. We denote by $\mathbf{F\acute{E}t}(X)$ the subcategory of $\mathbf{DM}_{/X}$ whose objects are finite [30, Df. 3.2.4] and étale morphisms $Y \longrightarrow X$ and whose morphisms are finite and étale morphisms over X. We will abuse notation and write $A^{\mathit{eff}}(X)$ for the effective Burnside ∞-category of $\mathbf{F\acute{E}t}(X)$.

D.24. **Example.** Suppose X a connected, noetherian scheme, suppose x a geometric point of X. Then if $\pi_1^{\text{ét}}(X,x)$ is the étale fundamental group of X, then by Grothendieck's Galois duality [33, Exp. V, §7], the ∞-category $\mathbf{F\acute{E}t}(X)$ is canonically equivalent to the ∞-category $NB^{fin}_{\pi_1^{\text{ét}}(X,x)}$ of Ex. B, whence we have a canonical equivalence

$$A^{eff}(\pi_1^{\text{ét}}(X,x)) \simeq A^{eff}(X).$$

(We can, of course, relax the condition that X be connected by passing to the étale fundamental groupoid.)

Restricting the Mackey functor $\mathbf{K} \circ \mathscr{M}_{\mathbf{DM}}$ of Nt. D.19 to

$$A^{eff}(X) \subset A^{eff}(\mathbf{DM}, \mathbf{DM}_{\mathscr{F}\mathscr{P}}, \mathbf{DM}),$$

we obtain a $\pi_1^{\text{ét}}(X,x)$-equivariant K-theory spectrum

$$\mathbf{K}_{\pi_1^{\text{ét}}(X,x)}(X) \colon A^{eff}(\pi_1^{\text{ét}}(X,x)) \longrightarrow \mathbf{Sp},$$

whose value on the $\pi_1^{\text{ét}}(X,x)$-set $[\pi_1^{\text{ét}}(X,x)/H]$ (with $H \leq \pi_1^{\text{ét}}(X,x)$ open) is the algebraic K-theory of the étale cover $X' \longrightarrow X$ corresponding to H. Corresponding to the unit of $\mathbf{K}(X)$, we obtain a morphism of Mackey functors

$$\mathbf{S}_{\pi_1^{\text{ét}}(X,x)} \longrightarrow \mathbf{K}_{\pi_1^{\text{ét}}(X,x)}(X).$$

The Segal–tom Dieck splitting thus provides a collection of maps

$$\Sigma^{\infty}_{+} B(N_{\pi_1^{\text{ét}}(X,x)}H/H) \longrightarrow \mathbf{K}(X),$$

one for each conjugacy class of open subgroups $H \leq \pi_1^{\text{ét}}(X,x)$.

SPECTRAL MACKEY FUNCTORS AND EQUIVARIANT ALGEBRAIC K-THEORY (II)

CLARK BARWICK, SAUL GLASMAN, AND JAY SHAH

Abstract. We study the "higher algebra" of spectral Mackey functors, which the first named author introduced in Part I of this paper. In particular, armed with our new theory of symmetric promonoidal ∞-categories and a suitable generalization of the second named author's Day convolution, we endow the ∞-category of Mackey functors with a well-behaved symmetric monoidal structure. This makes it possible to speak of *spectral Green functors* for any operad O. We also answer a question of Mathew, proving that the algebraic K-theory of group actions is lax symmetric monoidal. We also show that the algebraic K-theory of derived stacks provides an example. Finally, we give a very short, new proof of the equivariant Barratt–Priddy–Quillen theorem, which states that the algebraic K-theory of the category of finite G-sets is simply the G-equivariant sphere spectrum.

Contents

0. Summary

This paper is part of an effort to give a complete description of the structures available on the algebraic K-theory of varieties and schemes (and even of various derived stacks) with all their concomitant functorialities and homotopy coherences.

So suppose X a scheme (quasicompact and quasiseparated). The derived tensor product $\otimes^{\mathbf{L}}$ on perfect complexes on X defines a symmetric monoidal structure on the derived category D_X^{perf} of perfect complexes on X. With a little more effort, one can lift this structure to a symmetric monoidal structure on the stable ∞-category of perfect complexes on X. This suffices to get a product on algebraic K-theory

$$\otimes\colon K(X) \wedge K(X) \longrightarrow K(X)$$

that is associative and commutative up to coherent homotopy. Thus, $K(X)$ has not only the structure of a connective spectrum, but also the structure of a *connective E_∞ ring spectrum*. This is an exceedingly rich structure: not only do the homotopy groups $K_*(X)$ form a graded commutative ring, but these homotopy groups also support (in a functorial way) a tremendous amount of structure involving intricate higher homotopy operations called *Toda brackets*. Still more information (in the form of *Dyer-Lashof operations*) can be found on the $\mathbf{F}_p$-cohomology of $K(X)$.

Now for any morphism $f\colon Y \longrightarrow X$ of schemes, the derived functor

$$\mathbf{L}f^\star\colon D_X^{qcoh} \longrightarrow D_Y^{qcoh}$$

on the category of complexes with quasicoherent cohomology preserves perfect complexes, and the resulting functor $\mathbf{L}f^\star\colon D_X^{perf} \longrightarrow D_Y^{perf}$ induces a morphism

$$f^\star\colon K(X) \longrightarrow K(Y)$$

on the algebraic K-theory. The functor $\mathbf{L}f^\star$ is compatible with the derived tensor product, in the sense that for any perfect complexes E and F on X, there is a canonical isomorphism

$$\mathbf{L}f^\star(E \otimes^{\mathbf{L}} F) \simeq (\mathbf{L}f^\star E) \otimes^{\mathbf{L}} (\mathbf{L}f^\star F).$$

Again this can be lifted to the level of stable ∞-categories, whence the induced morphism $f^\star$ on K-theory turns out to be a morphism of connective E_∞ ring spectra. This implies that the induced homomorphism on homotopy groups

$$f^\star\colon K_*(X) \longrightarrow K_*(Y)$$

is a homomorphism of graded commutative rings, and it must respect all the higher homotopy operations on $K_*(X)$ as well.

Furthermore, one can fit all the functors $\mathbf{L}f^\star$ together to get a presheaf $U \rightsquigarrow D_U^{perf}$ on the big site of all schemes. This can even be viewed as a presheaf of stable ∞-categories, which suffices to give us a presheaf of connective spectra $U \rightsquigarrow K(U)$. Since the morphisms $f^\star$ are morphisms of connective E_∞ ring spectra, we can regard this as presheaf of E_∞ ring spectra.

If one wanted, one might "externalize" the product on K-theory in the following manner. For any two schemes X and Y over a base scheme S, one may define an external tensor product

$$\boxtimes^{\mathbf{L}}\colon D_X^{perf} \times D_X^{perf} \longrightarrow D_{X\times_S Y}^{perf}$$

by the assignment $(E, F) \rightsquigarrow (\mathbf{L}\,\mathrm{pr}_1^\star E) \otimes^{\mathbf{L}} (\mathbf{L}\,\mathrm{pr}_2^\star F)$. Note that we have natural equivalences

$$(\mathbf{L}f^\star E) \boxtimes^{\mathbf{L}} (\mathbf{L}g^\star F) \simeq \mathbf{L}(f \times g)^\star(E \boxtimes^{\mathbf{L}} F)$$

If we lift this to the level of stable ∞-categories, this gives rise to an external pairing

$$\boxtimes\colon K(X) \wedge K(Y) \longrightarrow K(X \times_S Y),$$

which is functorial (contravariantly) in X and Y. The E_∞ product on $K(X)$ can now be obtained by pulling back this external pairing along the diagonal map:

$$K(X) \wedge K(X) \longrightarrow K(X \times_S X) \longrightarrow K(X).$$

A morphism of schemes $f\colon Y \longrightarrow X$ may induce morphisms in the *covariant* direction as well. The pushforward $\mathbf{R}f_\star\colon D^{qcoh}_Y \longrightarrow D^{qcoh}_X$ generally will not preserve perfect complexes. If, however, f is flat and proper, then for any perfect complex E, the complex $\mathbf{R}f_\star E$ *is* perfect. Thus in this case $\mathbf{R}f_\star$ restricts to a functor $\mathbf{R}f_\star\colon D^{perf}_Y \longrightarrow D^{perf}_X$, and after lifting this to the stable ∞-categories, we find an induced morphism

$$f_\star\colon K(Y) \longrightarrow K(X)$$

on the algebraic K-theory. One thus obtains a covariant functor $U \rightsquigarrow K(U)$, but only with respect to flat and proper morphisms. Observe, however, that since the functors $\mathbf{R}f_\star$ do not commute with the derived tensor product, this functor is *not* valued in ring spectra.

Nevertheless, if $f\colon Y \longrightarrow X$ is proper and flat, we do have an algebraic structure preserved by $\mathbf{R}f_\star$. Observe that one may regard $K(Y)$ as a module over the E_∞ ring spectrum $K(X)$ via $f^\star$. For any perfect complexes E on Y and F on X, one has a canonical equivalence

$$(\mathbf{R}f_\star E) \otimes^{\mathbf{L}} F \simeq \mathbf{R}f_\star(E \otimes^{\mathbf{L}} \mathbf{L}f^\star F)$$

of perfect complexes; this is the usual projection formula [8, Exp. III, Pr. 3.7]. At the level of K-theory, this translates to the observation that the morphism

$$f_\star\colon K(Y) \longrightarrow K(X)$$

is a morphism of connective $K(X)$-modules. The induced map on homotopy groups

$$f_\star\colon K_*(Y) \longrightarrow K_*(X)$$

is therefore a homomorphism of $K_*(X)$-modules.

Note that the *external* tensor product $\boxtimes^{\mathbf{L}}$ is actually perfectly compatible with the pushforwards, in the sense that one has natural equivalences

$$(\mathbf{R}f_\star E) \boxtimes^{\mathbf{L}} (\mathbf{R}g_\star F) \simeq \mathbf{R}(f \times g)_\star(E \boxtimes^{\mathbf{L}} F),$$

so on K-theory the external product $\boxtimes\colon K(X) \wedge K(Y) \longrightarrow K(X \times_S Y)$ is functorial (covariantly) in X and Y.

Last, but certainly not least, there is a compatibility between the morphisms $f^\star$ and the morphisms $g_\star$, which results from the base change theorem for complexes [8, Exp. IV, Pr. 3.1.0]. Suppose that

$$\begin{array}{ccc} Y' & \xrightarrow{g} & Y \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle f} \\ X' & \xrightarrow[g]{} & X \end{array}$$

is a pullback square of schemes in which the horizontal maps g are flat and proper. Then the canonical morphism

$$\mathbf{L}f^\star \mathbf{R}g_\star \longrightarrow \mathbf{R}g_\star \mathbf{L}f^\star$$

is an objectwise equivalence of functors $D^{perf}_{X'} \longrightarrow D^{perf}_Y$. This translates to the condition that there is a canonical homotopy

$$f^\star g_\star \simeq g_\star f^\star\colon K(X') \longrightarrow K(Y)$$

of morphisms of $K(X)$-modules. In fact, this compatibility between the pullbacks and the pushforwards, combined with the compatibility between $f_\star$ and the external tensor product, allows us to *deduce* the projection formula.

Let us summarize the structure we've found on the assignment $U \rightsquigarrow K(U)$:

- For every scheme X, we have an E_∞ ring spectrum $K(X)$. Moreover, for any two schemes X and Y over a base S, one has an external pairing
$$\boxtimes\colon K(X) \wedge K(Y) \longrightarrow K(X \times_S Y).$$
- For every morphism $f\colon Y \longrightarrow X$, we have a pullback morphism
$$f^\star\colon K(X) \longrightarrow K(Y),$$
which is compatible with the external pairings and thus also with the E_∞ product.
- For every flat and proper morphism $f\colon Y \longrightarrow X$, we have a pushforward morphism
$$f_\star\colon K(Y) \longrightarrow K(X),$$
which is compatible with the external pairings and thus (in light of the next condition) also with the $K(X)$-module structure.
- For any pullback square
$$\begin{array}{ccc} Y' & \xrightarrow{g} & Y \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle f} \\ X' & \xrightarrow[g]{} & X \end{array}$$
in which the horizontal maps g are flat and proper, we have a canonical homotopy
$$f^\star g_\star \simeq g_\star f^\star\colon K(X') \longrightarrow K(Y).$$
of morphisms of $K(X)$-modules.

In this paper, we will demonstrate that these structures, along with all of their homotopy coherences, are neatly packaged in a *spectral Green functor* on the category of schemes.

This structure is the origin of both the $\mathrm{Gal}(E/F)$-equivariant E_∞ ring spectrum structure on the algebraic K-theory of a Galois extension $E \supset F$ and the cyclotomic structure on the p-typical curves on a smooth $\mathbf{F}_p$-scheme. For the former, see 9.7, and for the latter, see the forthcoming paper [7].

In order to describe all the structure we see here, we study the "higher algebra" (in the sense of Lurie's book [19], for example) of spectral Mackey functors, which we introduced in Part I of this paper [4]. The ∞-category of spectral Mackey functors turns out to admit all the same well-behaved structures as the ∞-category of spectra itself. In particular, the ∞-category of Mackey functors admits a well-behaved symmetric monoidal structure. This, combined with Saul Glasman's convolution for ∞-categories [11], makes it possible to speak of E_1 algebras, E_∞ algebras, or indeed O-algebras for any operad O in this context; these are called *O-Green functors*.

We use this framework to provide a very simple answer to a question posed to us by Akhil Mathew, in which we demonstrate that the functor that assigns to any ∞-category with an action of a finite group G its equivariant algebraic K-theory is lax symmetric monoidal. We also show that the algebraic K-theory of derived stacks with its transfer maps as described above offers an example of an E_∞ Green functor. We also use this theory to give a new proof of the equivariant Barratt–Priddy–Quillen theorem, which states that the algebraic K-theory of the category of finite G-sets is simply the G-equivariant sphere spectrum. (In fact, we will generalize this result dramatically.)

Warning. Let us emphasize that E_∞-Green functors for a finite group G are *not* equivalent to algebras in G-equivariant spectra structured by the equivariant linear isometries operad on a complete G-universe. To describe the latter in line with the discussion here – and to find such structures on algebraic K-theory spectra – it is necessary to develop elements of the theory of G-∞-categories. This we do in the forthcoming joint paper [5].

Acknowledgments. We have had very helpful conversations with David Ayala and Mike Hill about the contents of this paper, its predecessor, and its sequels. We also thank the other participants of the Bourbon Seminar – Emanuele Dotto, Marc Hoyois, Denis Nardin, and Tomer Schlank – for their many, many insights.

1. ∞-ANTI-OPERADS AND SYMMETRIC PROMONOIDAL ∞-CATEGORIES

One of the many complications that arises when one combines an ∞-category and its opposite in the way we have in our construction of the effective Burnside ∞-category is that our constructions are extremely intolerant of asymmetries in basic definitions. This complication rears its head the moment we want to contemplate the symmetric monoidal structure on the Burnside ∞-category. In effect, the description of a symmetric monoidal ∞-categories given in [19, Ch. 4] forces one to specify the data of maps *out of* various tensor products in a suitably compatible fashion. Thus symmetric monoidal categories are there identified as certain ∞-*operads*. But since we are also working with opposites of symmetric monoidal ∞-categories, we will come face-to-face with circumstances in which we must identify the data of maps *into* various tensor products in a suitably compatible fashion. We will call the resulting opposites of ∞-operads ∞-*anti-operads*.[1] Awkward as this may seem, it cannot be avoided.

1.1. **Notation.** Let $\Lambda(\mathbf{F})$ denote the following ordinary category. The objects will be finite sets, and a morphism $J \longrightarrow I$ will be a map $J \longrightarrow I_+$; one composes $\psi\colon K \longrightarrow J_+$ with $\phi\colon J \longrightarrow I_+$ by forming the composite

$$K \xrightarrow{\psi} J_+ \xrightarrow{\phi_+} I_{++} \xrightarrow{\mu} I_+,$$

where $\mu\colon I_{++} \longrightarrow I_+$ is the map that simply identifies the two added points. (Of course $\Lambda(\mathbf{F})$ is equivalent to the category $\mathbf{F}_*$ of pointed finite sets, but we prefer to think of the objects of $\Lambda(\mathbf{F})$ as unpointed. This is the natural perspective on this category from the theory of operator categories [1].)

1.2. **Definition.** (1.2.1) An ***∞-anti-operad*** is an inner fibration

$$p\colon O_\otimes \longrightarrow \mathrm{N}\Lambda(\mathbf{F})^{op}$$

whose opposite

$$p^{op}\colon (O_\otimes)^{op} \longrightarrow \mathrm{N}\Lambda(\mathbf{F})$$

is an ∞-operad.

[1] We do not know a standard name for this structure. In a previous verion of this paper, CB called these "cooperads," but this conflicts with better-known terminology.

(1.2.2) If $p\colon O_{\otimes} \longrightarrow \mathrm{N}\Lambda(\mathbf{F})^{op}$ is an ∞-anti-operad, then an edge of $O_{\otimes}$ will be said to be ***inert*** if it is cartesian over an edge of $\mathrm{N}\Lambda(\mathbf{F})^{op}$ that corresponds to an inert map in $\Lambda(\mathbf{F})$, that is, a map $\phi\colon J \longrightarrow I_{+}$ such that the induced map $\phi^{-1}(I) \longrightarrow I$ is a bijection [19, Df. 2.1.1.8], [1, Df. 8.1].

(1.2.3) A cartesian fibration

$$q\colon X_{\otimes} \longrightarrow O_{\otimes}$$

will be said to ***exhibit*** $X_{\otimes}$ ***as an*** $O_{\otimes}$***-monoidal*** ∞***-category*** just in case the cocartesian fibration

$$q^{op}\colon (X_{\otimes})^{op} \longrightarrow (O_{\otimes})^{op}$$

exhibits $(X_{\otimes})^{op}$ as an $(O_{\otimes})^{op}$-monoidal ∞-category in the sense of [19, Df. 2.1.2.13]. When $O_{\otimes} = \mathrm{N}\Lambda(\mathbf{F})^{op}$, we will say that q ***exhibits*** $X_{\otimes}$ ***as a symmetric monoidal*** ∞***-category***.

(1.2.4) A ***morphism*** $f\colon O_{\otimes} \longrightarrow P_{\otimes}$ ***of*** ∞***-anti-operads*** is a morphism over $\mathrm{N}\Lambda(\mathbf{F})^{op}$ that carries inert edges to inert edges. If $O_{\otimes}$ and $P_{\otimes}$ are symmetric monoidal ∞-categories, then f is a ***symmetric monoidal functor*** if it carries all cartesian edges to cartesian edges.

1.3. **Example.** Suppose C an ∞-category. We define the ***cartesian*** ∞***-anti-operad*** as

$$p\colon C_{\times} := ((C^{op})^{\sqcup})^{op} \longrightarrow \mathrm{N}\Lambda(\mathbf{F})^{op},$$

where the notation $(\cdot)^{\sqcup}$ refers to the cocartesian ∞-operad [19, Cnstr. 2.4.3.1]. If C is an ∞-category that admits all products, then the functor p exhibits $C_{\times}$ as a symmetric monoidal ∞-category [19, Rk. 2.4.3.4].

An object (I, X) of $C_{\times}$ consists of a finite set I and a family $\{X_i \mid i \in I\}$; a morphism $(\phi, \omega)\colon (I, X) \longrightarrow (J, Y)$ of $C_{\times}$ consists of a map of finite sets $\phi\colon J \longrightarrow I_{+}$ and a family of morphisms

$$\left\{\omega_j\colon X_{\phi(j)} \longrightarrow Y_j \;\middle|\; j \in \phi^{-1}(I)\right\}$$

of C. If C admits finite products, then the morphisms ω_j determine and are determined by a family of morphisms

$$\left\{ \omega_{J_i}\colon X_i \longrightarrow \prod_{j \in J_i} Y_j \;\middle|\; i \in I \right\};$$

here J_i denotes the fiber $\phi^{-1}(i)$.

Observe that the cartesian ∞-anti-operad is significantly simpler to define than the cartesian ∞-operad. Note also that $(\Delta^0)_{\times} = \mathrm{N}\Lambda(\mathbf{F})^{op}$.

It is extremely useful to note that the condition that an ∞-operad $C^{\otimes}$ be a symmetric monoidal ∞-category can be broken into two conditions:

(1) The first of these is *corepresentability* [19, Df. 6.2.4.3]; this is the condition that the functors $\mathrm{Map}^{\xi_I}_{C^{\otimes}}(x_I, -)\colon C \longrightarrow \mathbf{Top}$ be corepresentable, where ξ_I is the unique active map $I \longrightarrow *$ in $\Lambda(\mathbf{F})$. A compact expression of this is simply to say (as Lurie does) that the inner fibration $C^{\otimes} \longrightarrow N\Lambda(\mathbf{F})$ is locally cocartesian.

(2) The second condition is *symmetric promonoidality*. This can be expressed in a number of ways. One may say that for any active map $\phi\colon J \longrightarrow I$ of $\Lambda(\mathbf{F})$, for

any object $x_J \in C^{\otimes}_J$, and for any object $z \in C$, the natural map

$$\int^{y_I \in C^{\otimes}_I} \mathrm{Map}^{\xi_I}_{C^{\otimes}}(y_I, z) \times \mathrm{Map}^{\phi}_{C^{\otimes}}(x_J, y_I) \longrightarrow \mathrm{Map}^{\xi_J}_{C^{\otimes}}(x_J, z)$$

is an equivalence; this is an operadic version of the condition expressed in [19, Ex. 6.2.4.9]. Equivalently, $C^{\otimes}$ is a symmetric promonoidal ∞-category if it represents a commutative algebra object in the ∞-category of ∞-categories and profunctors. In light of [19, §B.3], we make the following definition.

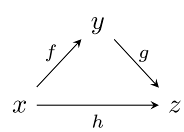
1.4. **Definition.** We will say that an ∞-operad $C^{\otimes}$ is ***symmetric promonoidal*** if the structure map $C^{\otimes} \longrightarrow N\Lambda(\mathbf{F})$ is a flat inner fibration [19, Df. B.3.8]. Similarly, we will say that an ∞-anti-operad $C_{\otimes}$ is ***symmetric promonoidal*** if the structure map $C_{\otimes} \longrightarrow N\Lambda(\mathbf{F})^{op}$ is a flat inner fibration.

Our claim now is that the conjunction of these two conditions are equivalent to the condition that $C^{\otimes}$ be a symmetric monoidal ∞-category. That is, we claim that a symmetric monoidal ∞-category is *precisely* a corepresentable symmetric promonoidal ∞-category. This follows immediately from the following.

1.5. **Proposition.** *The following are equivalent for an inner fibration $p\colon X \longrightarrow S$.*

(1.5.1) The inner fibration p is flat and locally cocartesian.
(1.5.2) The inner fibration p is cocartesian.

Proof. The second condition implies the first by [19, Ex. B.3.11]. Let us show that the first condition implies the second. By [16, Pr. 2.4.2.8], it suffices to consider the case in which $S = \Delta^2$, and to show that for any section of p given by a commutative triangle



in which f and g are locally p-cocartesian, the edge h is locally p-cocartesian as well.

In this case, by [16, Cor. 3.3.1.2], we can find a cocartesian fibration $q\colon Y \longrightarrow \Delta^2$ along with an equivalence

$$\phi\colon X \times_{\Delta^2} \Lambda^2_1 \xrightarrow{\sim} Y \times_{\Delta^2} \Lambda^2_1$$

of cocartesian fibrations over Λ^2_1. Now since p is flat, the inclusion $X \times_{\Delta^2} \Lambda^2_1 \hookrightarrow X$ is a categorical equivalence over Δ^2. Consequently, we may lift to obtain a map $\psi\colon X \longrightarrow Y$ over Δ^2 extending ϕ. This map is a categorical equivalence since both p and q are flat.

Now $\psi(f) = \phi(f)$ and $\psi(g) = \phi(g)$ are q-cocartesian, whence so is $\psi(h)$. The stability of relative colimits under categorical equivalences [16, Pr. 4.3.1.6], in light of [16, Ex. 4.3.1.4], now implies that h is p-cocartesian. □

One reason to treasure symmetric promonoidal structures is the fact that, as we shall now prove, they are precisely the structure needed on an ∞-category C in order for $\mathrm{Fun}(C, D)$ to admit a *Day convolution* symmetric monoidal structure.[2]

[2]We would like to acknowledge that Dylan Wilson has independently made this observation.

To explain, suppose first $C^{\otimes}$ a small symmetric monoidal ∞-category, and suppose $D^{\otimes}$ a symmetric monoidal ∞-category such that D admits all colimits, and the tensor product preserves colimits separately in each variable. In [11], Glasman constructs a symmetric monoidal structure on the functor ∞-category $\mathrm{Fun}(C, D)$ which is the natural ∞-categorical generalization of Day's convolution product. As in Day's construction, the convolution $F \otimes G$ of two functors $F, G\colon C \longrightarrow D$ in Glasman's symmetric monoidal structure is given by the left Kan extension of the composite

$$C \times C \xrightarrow{(F,G)} D \times D \xrightarrow{\otimes} D$$

along the tensor product $\otimes\colon C \times C \longrightarrow C$.

In particular, for any finite set I, and for any I-tuple $\{F_i\}_{i \in I}$ of functors $C \longrightarrow D$, the value of the tensor product is given by the coend

$$\left(\bigotimes_{i \in I} F_i\right)(x) \simeq \int^{u_I \in C_I^{\otimes}} \mathrm{Map}^{\xi_I}_{C^{\otimes}}(u_I, x) \otimes \bigotimes_{i \in I} F_i(u_i).$$

Equivalently, the Day convolution on $\mathrm{Fun}(C, D)$ is the essentially unique symmetric monoidal structure that enjoys the following criteria:

- ▶ The tensor product
$$- \otimes -\colon \mathrm{Fun}(C, D) \times \mathrm{Fun}(C, D) \longrightarrow \mathrm{Fun}(C, D)$$
preserves colimits separately in each variable.
- ▶ The functor given by the composite
$$C^{op} \times D \xrightarrow{j \times \mathrm{id}} \mathrm{Fun}(C, \mathbf{Kan}) \times D \xrightarrow{m} \mathrm{Fun}(C, D)$$
is symmetric monoidal, where j denotes the Yoneda embedding, and m is the functor corresponding to the composition
$$\mathrm{Fun}(C, \mathbf{Kan}) \longrightarrow \mathrm{Fun}(D \times C, D \times \mathbf{Kan}) \longrightarrow \mathrm{Fun}(D \times C, D)$$
in which the first functor is the obvious one, and the functor $D \times \mathbf{Kan} \longrightarrow D$ is the tensor functor $(X, K) \rightsquigarrow X \otimes K$ of [16, §4.4.4].

Conveniently, we can extend Glasman's Day convolution to situations in which $C^{\otimes}$ is only symmetric promonoidal.

1.6. **Proposition.** *For any symmetric promonoidal ∞-category $C^{\otimes}$ and any symmetric monoidal ∞-category $D^{\otimes}$ such that D admits all colimits and $\otimes\colon D \times D \longrightarrow D$ preserves colimits separately in each variable,* $\mathrm{Fun}(C, D)$ *admits a symmetric monoidal structure such that the E_∞-algebras therein are morphisms of ∞-operads $C^{\otimes} \longrightarrow D^{\otimes}$.*

Proof. The results of the first two sections of [11] hold when $C^{\otimes}$ is symmetric promonoidal with only one change: in the proof of [11, Lm. 2.3], the reference to [16, Pr. 3.3.1.3] should be replaced with a reference to [19, Pr. B.3.14]. Consequently, our claim follows from [11, Prs. 2.11 and 2.12]. □

1.7. Once again, for any finite set I, and for any I-tuple $\{F_i\}_{i \in I}$ of functors $C \longrightarrow D$, the value of the tensor product is given by the coend

$$\left(\bigotimes_{i \in I} F_i\right)(x) \simeq \int^{u_I \in C_I^{\otimes}} \mathrm{Map}^{\xi_I}_{C^{\otimes}}(u_I, x) \otimes \bigotimes_{i \in I} F_i(u_i).$$

2. The symmetric promonoidal structure on the effective Burnside ∞-category

Suppose C a disjunctive ∞-category. The product on C does not induce the product on the effective Burnside ∞-category $A^{eff}(C)$. (Indeed, recall that the effective Burnside ∞-category admits direct sums, and these direct sums are induced by the *coproduct* in C.) However, a product on C (if it exists) *does* induce a symmetric monoidal structure on $A^{eff}(C)$. The construction of the previous example is just what we need to describe this structure, and it will work for a broad class of disjunctive triples – which we call *cartesian* – as well.

It turns out to be convenient to consider situations in which C does not actually have products. In this case, the effective Burnside ∞-category $A^{eff}(C)$ admits not a symmetric monoidal structure, but only a symmetric promonoidal structure, which suffices to get the Day convolution on ∞-categories of Mackey functors.

2.1. **Notation.** Suppose $(C, C_\dagger, C^\dagger)$ a disjunctive triple. We now define a triple structure $(C_\times, (C_\times)_\dagger, (C_\times)^\dagger)$ on $C_\times$ in the following manner. A morphism

$$(\phi, \omega)\colon (I, X) \longrightarrow (J, Y)$$

of $C_\times$ will be ingressive just in case ϕ is a bijection, and each morphism

$$\omega_j\colon X_{\phi(j)} \longrightarrow Y_j$$

is ingressive. The morphism (ϕ, ω) will be egressive just in case each morphism

$$\omega_j\colon X_{\phi(j)} \longrightarrow Y_j$$

is egressive (with no condition on ϕ).

It is a trivial matter to verify the following.

2.2. **Lemma.** *Suppose $(C, C_\dagger, C^\dagger)$ a left complete disjunctive triple. Then the triple*

$$(C_\times, (C_\times)_\dagger, (C_\times)^\dagger)$$

is adequate in the sense of [4, Df. 5.2].

In particular, for any left complete disjunctive triple $(C, C_\dagger, C^\dagger)$, one may consider the effective Burnside ∞-category

$$A^{eff}(C_\times, (C_\times)_\dagger, (C_\times)^\dagger).$$

2.3. **Example.** Note in particular that

$$((\Delta^0)_\times, ((\Delta^0)_\times)_\dagger, ((\Delta^0)_\times)^\dagger) \simeq (\mathrm{N}\Lambda(\mathbf{F})^{op}, \iota\mathrm{N}\Lambda(\mathbf{F})^{op}, \mathrm{N}\Lambda(\mathbf{F})^{op}),$$

whence one proves easily that the inclusion

$$\mathrm{N}\Lambda(\mathbf{F}) \simeq (((\Delta^0)_\times)^\dagger)^{op} \hookrightarrow A^{eff}((\Delta^0)_\times, ((\Delta^0)_\times)_\dagger, ((\Delta^0)_\times)^\dagger)$$

is an equivalence.

We'll use the following pair of results. They follow the same basic pattern as [4, Lms. 11.4 and 11.5]; in particular, they too follow immediately from the first author's "omnibus theorem" [4, Th. 12.2].

2.4. **Lemma.** *Suppose $(C, C_\dagger, C^\dagger)$ a left complete disjunctive triple. Then the natural functor*

$$A^{eff}(C_\times, (C_\times)_\dagger, (C_\times)^\dagger) \longrightarrow A^{eff}((\Delta^0)_\times, ((\Delta^0)_\times)_\dagger, ((\Delta^0)_\times)^\dagger)$$

is an inner fibration.

2.5. **Lemma.** *Suppose $(C, C_\dagger, C^\dagger)$ a left complete disjunctive triple. Then for any object Y of $C_\times$ lying over an object $J \in (\Delta^0)_\times$ and any inert morphism $\phi\colon I \longrightarrow J$ of $N\Lambda(\mathbf{F})$, there exists a cocartesian edge $Y \longrightarrow X$ for the inner fibration*

$$A^{\mathit{eff}}(C_\times, (C_\times)_\dagger, (C_\times)^\dagger) \longrightarrow A^{\mathit{eff}}((\Delta^0)_\times, ((\Delta^0)_\times)_\dagger, ((\Delta^0)_\times)^\dagger)$$

lying over the image of ϕ under the equivalence of Ex. 2.3.

Now we can go about defining the symmetric promonoidal structure on the effective Burnside ∞-category of a disjunctive triple.

2.6. **Notation.** For any disjunctive triple $(C, C_\dagger, C^\dagger)$, we define $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^\otimes$ as the pullback

$$A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^\otimes := A^{\mathit{eff}}(C_\times, (C_\times)_\dagger, (C_\times)^\dagger) \times_{A^{\mathit{eff}}((\Delta^0)_\times, ((\Delta^0)_\times)_\dagger, ((\Delta^0)_\times)^\dagger)} \mathrm{N}\Lambda(\mathbf{F}),$$

equipped with its canonical projection to $\mathrm{N}\Lambda(\mathbf{F})$. Note that because the inclusion

$$\mathrm{N}\Lambda(\mathbf{F}) \hookrightarrow A^{\mathit{eff}}((\Delta^0)_\times, (\Delta^0)_{\times,\dagger}, (\Delta^0)_\times^\dagger)$$

is an equivalence, it follows that the projection functor

$$A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^\otimes \longrightarrow A^{\mathit{eff}}(C_\times, (C_\times)_\dagger, (C_\times)^\dagger)$$

is actually an equivalence.

2.7. **Remark.** Suppose $(C, C_\dagger, C^\dagger)$ a disjunctive triple. The objects of the total ∞-category $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^\otimes$ are pairs (I, X_I) consisting of a finite set I and an I-tuple $X_I = (X_i)_{i\in I}$ of objects of C. A morphism

$$(J, Y_J) \longrightarrow (I, X_I)$$

of $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^\otimes$ can be thought of as a morphism $\phi\colon J \longrightarrow I$ of $\Lambda(\mathbf{F})$ and a collection of diagrams

$$\left\{ \begin{array}{ccc|c} & U_{\phi(j)} & & \\ \swarrow & & \searrow & j \in \phi^{-1}(I) \\ Y_j & & X_{\phi(j)}, & \end{array} \right\}$$

such that for any $j \in J$, the morphism $U_{\phi(j)} \rightarrowtail X_{\phi(j)}$ is ingressive, and the morphism

$$U_{\phi(j)} \twoheadrightarrow Y_j$$

is egressive.

Composition is then defined by pullback; that is, a 2-simplex

$$(K, Z_K) \longrightarrow (J, Y_J) \longrightarrow (I, X_I)$$

consists of morphisms $\psi\colon K \longrightarrow J$ and $\phi\colon J \longrightarrow I$ of $\Lambda(\mathbf{F})$ along with a collection of diagrams

$$\left\{ \begin{array}{ccccc|c} & & W_{\phi(\psi(k))} & & & \\ & \swarrow & & \searrow & & \\ & V_{\psi(k)} & & U_{\phi(\psi(k))} & & k \in (\phi\psi)^{-1}(I) \\ \swarrow & & \searrow \quad \swarrow & & \searrow & \\ Z_k & & Y_{\psi(k)} & & X_{\phi(\psi(k))} & \end{array} \right\}$$

in which the square in the middle exhibits each W_i (for $i \in I$) as the iterated fiber product over U_i of the set of objects $\{V_j \times_{Y_j} U_i \mid j \in J_i\}$. (Note that the left completeness is used to show that this iterated fiber product exists.)

In particular, $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^{\otimes}_{\{1\}}$ may be identified with the effective Burnside ∞-category $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)$ itself, and for any finite set I, the inert morphisms $\chi_i \colon I \longrightarrow \{i\}_+$ together induce an equivalence

$$A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^{\otimes}_{I} \xrightarrow{\sim} \prod_{i \in I} A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^{\otimes}_{\{i\}}.$$

For the proofs of the next few results it is convenient to introduce a bit of notation.

2.8. **Notation.** Suppose $(C, C_\dagger, C^\dagger)$ a triple, suppose A and B are two sets, and suppose $S \colon A \sqcup B \longrightarrow C$ a functor. Then let

$$C'_{/\{S_x \ ; \ S_y\}_{x \in A, y \in B}} \subseteq C_{/\{S_z\}_{z \in A \sqcup B}}$$

denote the full subcategory spanned by those objects such that the morphisms to the objects S_x are egressive and the morphisms to the objects S_y are ingressive. In particular, note that

$$\mathrm{Map}_{A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^{\otimes}}((J, Y_J), (*, X)) \simeq \iota C'_{/\{Y_j \ ; \ X\}_{j \in J}}.$$

We have almost proven the following.

2.9. **Proposition.** *For any left complete disjunctive triple* $(C, C_\dagger, C^\dagger)$*, the inner fibration*

$$A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^{\otimes} \longrightarrow \mathrm{N}\Lambda(\mathbf{F})$$

is an ∞*-operad.*

Proof. Following Rk. 2.7, it only remains to show that given an edge $\alpha \colon I \longrightarrow J$ in $\mathrm{N}\Lambda(\mathbf{F})$ and objects $(I, X), (J, Y)$ in $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^{\otimes}$, the cocartesian edges

$$\begin{array}{ccc} & (*, Y_j) & \\ \swarrow\!\!= & & \searrow \\ (J, Y) & & (*, Y_j), \end{array}$$

over the inert edges $\rho^j \colon J \longrightarrow *$ induce an equivalence

$$\mathrm{Map}^{\alpha}_{A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^{\otimes}}((I, X), (J, Y)) \longrightarrow \prod_{j \in J} \mathrm{Map}^{\rho^j \circ \alpha}_{A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^{\otimes}}((I, X), (*, Y_j)).$$

But this is indeed true, since the map identifies the left-hand side as

$$\prod_{j \in J} \iota C'_{/\{X_i \ ; \ Y_j\}_{i \in \alpha^{-1}(j)}}.$$ □

We now show that the ∞-operad $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^{\otimes}$ is symmetric promonoidal.

2.10. **Proposition.** *Suppose* $(C, C_\dagger, C^\dagger)$ *a left complete disjunctive triple. Then the* ∞*-operad*

$$p \colon A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^{\otimes} \longrightarrow \mathrm{N}\Lambda(\mathbf{F})$$

is symmetric promonoidal; that is, p *is a flat inner fibration.*

Proof. Suppose $\sigma\colon \Delta^2 \longrightarrow N\Lambda(\mathbf{F})$ a 2-simplex given by a diagram

$$\begin{array}{ccc} & J & \\ {}^{\alpha}\nearrow & & \searrow^{\beta} \\ I & \xrightarrow[\gamma]{} & K \end{array}$$

a 2-simplex of $N\Lambda(\mathbf{F})$. Suppose

$$\begin{array}{ccc} & (K,W) & \\ \swarrow & & \searrow \\ (I,X) & & (K,Z), \end{array}$$

an edge $\widetilde{\gamma}$ of

$$\Sigma := A^{\mathit{eff}}(C, C_{\dagger}, C^{\dagger})^{\otimes} \times_{N\Lambda(\mathbf{F}),\sigma} \Delta^2$$

lifting γ. Set

$$E := \Sigma_{(I,X)/\ /(K,Z)} \times_{N\Lambda(\mathbf{F})} \{J\}$$

be the ∞-category of factorizations of $\widetilde{\gamma}$ through Σ_J. Observe that an n-simplex of E is a cartesian functor $\widetilde{\mathscr{O}}(\Delta^{n+2})^{op} \longrightarrow (C_{\times}, (C_{\times})_{\dagger}, (C_{\times})^{\dagger})$ satisfying certain conditions.

We aim to show that E is weakly contractible. To this end, we will identify a full subcategory $E' \subset E$ whose inclusion functor admits a right adjoint such that E' contains a terminal object.

To begin, let us define a functor $\epsilon\colon E \times \Delta^1 \longrightarrow E$ extending the projection $E \times \{1\} \xrightarrow{\sim} E$ as follows: given non-negative integers $k \leq n$, let

$$f_{n,k}\colon \widetilde{\mathscr{O}}(\Delta^{n+3}) \longrightarrow \widetilde{\mathscr{O}}(\Delta^{n+2})$$

be the unique functor which on objects is given by

$$f_{n,k}(ij) := \begin{cases} 0j & \text{if } i \leq k+1 \text{ and } j \leq k+1; \\ 0(j-1) & \text{if } i \leq k+1 \text{ and } j > k+1; \\ (i-1)(j-1) & \text{if } i > k+1. \end{cases}$$

Then for every n-simplex $\sigma\colon \Delta^n \longrightarrow E$ corresponding to a functor

$$\overline{\sigma}\colon \widetilde{\mathscr{O}}(\Delta^{n+2})^{op} \longrightarrow C_{\times},$$

define $\epsilon(\sigma)\colon \Delta^n \times \Delta^1 \longrightarrow E$ to be the unique functor which sends the nondegenerate $(n+1)$-simplex

$$(0,0) \longrightarrow \cdots \longrightarrow (0,k) \longrightarrow (1,k) \longrightarrow \cdots \longrightarrow (1,n)$$

to the $(n+1)$-simplex $\Delta^{n+1} \longrightarrow E$ corresponding to the functor

$$\overline{\sigma} \circ f_{nk}^{op}\colon \widetilde{\mathscr{O}}(\Delta^{n+3})^{op} \longrightarrow C_{\times}.$$

It is easy (albeit tedious) to verify that the functors $\epsilon(\sigma)$ assemble to yield a unique functor ϵ. Now set

$$R := \epsilon|_{(E\times\{0\})}.$$

Given an object $\tau \in E$ displayed as a 2-simplex

$$\begin{array}{ccccc} & & (K,W) & & \\ & \swarrow & & \searrow & \\ & (J,Y_{01}) & & (K,Y_{12}) & \\ \swarrow & & \searrow \quad \swarrow & & \searrow \\ (I,X) & & (J,Y) & & (K,Z) \end{array}$$

of Σ, the edge $\epsilon_\tau\colon R(\tau) \longrightarrow \tau$ to be

$$\begin{array}{ccccccc} & & & (K,W) & & & \\ & & \swarrow & & /\!\!/ & & \\ & & (J,Y_{01}) & & (K,W) & & \\ & /\!\!/ & & \backslash\!\!\backslash \quad \swarrow & & \searrow & \\ & (J,Y_{01}) & & (J,Y_{01}) & & (K,Y_{12}) & \\ \swarrow & & \backslash\!\!\backslash \quad /\!\!/ & & \searrow \quad \swarrow & & \searrow \\ (I,X) & & (J,Y_{01}) & & (J,Y) & & (K,Z) \end{array}$$

From this, it is apparent that the essential image E' of R is the full subcategory spanned by those $\tau \in E$ such that the morphism $(J,Y_{01}) \longrightarrow (J,Y)$ is an equivalence, and by the dual of [16, Pr. 5.2.7.4], R is a colocalization functor.

We now define $(J,\overline{W}) \in C_\times$ by

$$\overline{W}_j := \begin{cases} W_{\beta(j)} & \text{if } \beta(j) \neq *; \\ \varnothing & \text{if } \beta(j) = *. \end{cases}$$

There is an obvious factorization of $(K,W) \longrightarrow (I,X)$ through $(J,\overline{W})$, and we define an object $\omega \in E'$ as

$$\begin{array}{ccccc} & & (K,W) & & \\ & \swarrow & & /\!\!/ & \\ & (J,\overline{W}) & & (K,W) & \\ \swarrow & & \backslash\!\!\backslash \quad \swarrow & & \searrow \\ (I,X) & & (J,\overline{W}) & & (K,Z) \end{array}$$

We now claim that ω is terminal in E'. Let $\tau \in E'$ be any object displayed as a 2-simplex

$$\begin{array}{ccccc} & & (K,W) & & \\ & \swarrow & & \searrow & \\ & (J,Y_{01}) & & (K,Y_{12}) & \\ \swarrow & & \searrow \quad \swarrow & & \searrow \\ (I,X) & & (J,Y) & & (K,Z) \end{array}$$

of Σ. We have a homotopy pullback square

$$\begin{array}{ccc}
\mathrm{Map}_E(\tau,\omega) & \longrightarrow & \mathrm{Map}_{\Sigma_{(I,X)/}}(d_2(\tau), d_2(\omega)) \\
\big\downarrow & & \big\downarrow{\scriptstyle \omega_*} \\
\Delta^0 & \underset{\tau}{\longrightarrow} & \mathrm{Map}_{\Sigma_{(I,X)/}}(d_2(\tau), \widetilde{\gamma})
\end{array}$$

and the terms on the right-hand side are in turn given as homotopy pullbacks

$$\begin{array}{ccc}
\mathrm{Map}_{\Sigma_{(I,X)/}}(d_2(\tau), d_2(\omega)) & \longrightarrow & \mathrm{Map}_{\Sigma}((J,Y),(J,\overline{W})) \\
\big\downarrow & & \big\downarrow{\scriptstyle d_2(\tau)^*} \\
\Delta^0 & \underset{d_2(\omega)}{\longrightarrow} & \mathrm{Map}_{\Sigma}((I,X),(J,\overline{W})),
\end{array}$$

and

$$\begin{array}{ccc}
\mathrm{Map}_{\Sigma_{(I,X)/}}(d_2(\tau), \widetilde{\gamma}) & \longrightarrow & \mathrm{Map}_{\Sigma}((J,Y),(K,Z)) \\
\big\downarrow & & \big\downarrow{\scriptstyle d_2(\tau)^*} \\
\Delta^0 & \underset{\widetilde{\gamma}}{\longrightarrow} & \mathrm{Map}_{\Sigma}((I,X),(K,Z)).
\end{array}$$

In light of the equivalence $(J, Y_{01}) \xrightarrow{\sim} (J, Y)$, we obtain equivalences

$$\mathrm{Map}_{\Sigma}((J,Y),(J,\overline{W})) \simeq \prod_{j\in J} \iota C'_{/\{(Y_{01})_j\ ;\ \overline{W}_j\}};$$
$$\mathrm{Map}_{\Sigma}((I,X),(J,\overline{W})) \simeq \prod_{j\in J} \iota C'_{/\{X_i\ ;\ \overline{W}_j\}_{i\in\alpha^{-1}(j)}}.$$

Under these equivalences the map $d_2(\tau)^*$ is given by $\prod_{j\in J}\phi_j$ where

$$\phi_j \colon \iota C'_{/\{(Y_{01})_j\ ;\ \overline{W}_j\}} \longrightarrow \iota C'_{/\{X_i\ ;\ \overline{W}_j\}_{i\in\alpha^{-1}(j)}}$$

is defined by postcomposition by the maps $(Y_{01})_j \longrightarrow X_i$ (with $i \in \alpha^{-1}(j)$). As a corollary of Cor. 2.11.1 below, we may factor the square in question into two homotopy pullback squares:

$$\begin{array}{ccccc}
\mathrm{Map}_{\Sigma_{(I,X)/}}(d_2(\tau), d_2(\omega)) & \longrightarrow & \mathrm{Map}_{(C_\times)^\dagger_{\mathrm{id}}}((J,\overline{W}),(J,Y_{01})) & \longrightarrow & \prod_{j\in J}\iota C'_{/\{(Y_{01})_j\ ;\ \overline{W}_j\}} \\
\big\downarrow & & \big\downarrow & & \big\downarrow \\
\Delta^0 & \longrightarrow & \mathrm{Map}_{(C_\times)^\dagger_{\alpha}}((J,\overline{W}),(I,X)) & \longrightarrow & \prod_{j\in J}\iota C'_{/\{X_i\ ;\ \overline{W}_j\}_{i\in\alpha^{-1}(j)}}.
\end{array}$$

Similarly, we factor the second square into two homotopy pullback squares:

$$\begin{array}{ccccc}
\mathrm{Map}_{\Sigma_{(I,X)/}}(d_2(\tau), \widetilde{\gamma}) & \longrightarrow & \mathrm{Map}_{(C_\times)^\dagger_{\beta}}((K,W),(J,Y_{01})) & \longrightarrow & \prod_{k\in K}\iota C'_{/\{(Y_{01})_j\ ;\ Z_k\}_{j\in\beta^{-1}(k)}} \\
\big\downarrow & & \big\downarrow & & \big\downarrow \\
\Delta^0 & \longrightarrow & \mathrm{Map}_{(C_\times)^\dagger_{\gamma}}((K,W),(I,X)) & \longrightarrow & \prod_{k\in K}\iota C'_{/\{X_i\ ;\ Z_k\}_{i\in\gamma^{-1}(k)}}
\end{array}$$

The map ω_* is then seen to be equivalent to the induced map between the fibers of the horizontal maps in the following commutative square:

$$\begin{array}{ccc} \mathrm{Map}_{(C_\times)^\dagger_{\mathrm{id}}}((J,\overline{W}),(J,Y_{01})) & \longrightarrow & \mathrm{Map}_{(C_\times)^\dagger_\alpha}((J,\overline{W}),(I,X)) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{(C_\times)^\dagger_\beta}((K,W),(J,Y_{01})) & \longrightarrow & \mathrm{Map}_{(C_\times)^\dagger_\gamma}((K,W),(I,X)). \end{array}$$

The left vertical map is the equivalence

$$\prod_{j\in\beta^{-1}(K)} \mathrm{Map}_{C^\dagger}(W_{\beta(j)},(Y_{01})_j) \xrightarrow{\sim} \prod_{k\in K}\prod_{j\in\beta^{-1}(k)} \mathrm{Map}_{C^\dagger}(W_k,(Y_{01})_j),$$

and the right vertical map is the equivalence

$$\prod_{j\in\beta^{-1}(K)}\prod_{i\in\alpha^{-1}(j)} \mathrm{Map}_{C^\dagger}(W_{\beta(j)},X_i) \xrightarrow{\sim} \prod_{k\in K}\prod_{i\in\gamma^{-1}(k)} \mathrm{Map}_{C^\dagger}(W_k,X_i),$$

so the square is in fact a homotopy pullback square and ω_* is an equivalence. Hence the mapping space $\mathrm{Map}_E(\tau,\omega)$ is contractible and ω is a terminal object of E'. This proves that E is weakly contractible. □

We digress briefly to give the following proposition, which is useful for studying the interaction of the over and undercategory functors with homotopy colimit diagrams.

2.11. **Proposition.** *Suppose C an ∞-category, and let $s\mathbf{Set}_{/C}$ be endowed with the model structure created by the forgetful functor to $s\mathbf{Set}$ equipped with the Joyal model structure. Then we have a Quillen adjunction*

$$C_{(-)/}\colon s\mathbf{Set}_{/C} \rightleftarrows (s\mathbf{Set}_{/C})^{op} : C_{/(-)}$$

between the over and undercategory functors.

Proof. The displayed functors are indeed adjoint to each other, since for objects $\phi\colon X \longrightarrow C$ and $\psi\colon Y \longrightarrow C$ we have natural isomorphisms

$$\mathrm{Hom}_{/C}(X, C_{\psi/}) \cong \mathrm{Hom}_{(X\sqcup Y)/}(X\star Y, C) \cong \mathrm{Hom}_{/C}(Y, C_{/\phi}).$$

To check that this adjunction is a Quillen adjunction, we check that $C_{(-)/}$ preserves cofibrations and trivial cofibrations. Let $\tau\colon \phi \longrightarrow \phi'$ be a map in $s\mathbf{Set}_{/C}$, and let $f = d_2(\tau)\colon X \longrightarrow X'$. If f is a monomorphism, by [16, 2.1.2.1] we have that $C_{\phi'/} \longrightarrow C_{\phi/}$ is a left fibration, hence by [16, 2.4.6.5] a categorical fibration. If f is a monomorphism and a categorical equivalence, by [16, 4.1.1.9] and [16, 4.1.1.1(4)] f is right anodyne, hence by [16, 2.1.2.5] $C_{\phi'/} \longrightarrow C_{\phi/}$ is a trivial Kan fibration. □

2.11.1. **Corollary.** *Let C be an ∞-category and suppose given a morphism f : $x \longrightarrow y$ in C and a diagram*

$$\begin{array}{ccccc} K & \overset{\phi}{\hookrightarrow} & L & \xrightarrow{p} & C \\ \downarrow & & \downarrow & \nearrow_{p'} & \\ K\sqcup\Delta^0 & \overset{\phi'}{\hookrightarrow} & L\sqcup\Delta^0 & & \end{array}$$

of simplicial sets where $\phi' = \phi \sqcup \mathrm{id}$ *and* $p'|_{\Delta^0}$ *selects* y*. Then we have a homotopy pullback square of* ∞*-categories*

$$\begin{array}{ccc} \{x\} \times_C C_{/p} & \xrightarrow{F} & C_{/p'} \\ \downarrow & & \downarrow \\ \{x\} \times_C C_{/p\circ\phi} & \xrightarrow{G} & C_{/p'\circ\phi'} \end{array}$$

where the vertical functors are given by change of diagram and the horizontal functors are to be defined.

Proof. Define the functor F as follows: the datum of an n-simplex $\Delta^n \longrightarrow \{x\} \times_C C_{/p}$ consists of a map $\alpha\colon \Delta^n \star L \longrightarrow C$ which restricts to p on L and to the constant map to x on Δ^n, and we use this to define $\Delta^n \star (L \sqcup \Delta^0) \longrightarrow C$ to be the unique map which restricts to α on $\Delta^n \star L$ and to

$$\Delta^n \star \Delta^0 \longrightarrow \Delta^1 \xrightarrow{f} C$$

on $\Delta^n \star \Delta^0$; this gives the n-simplex of $C_{/p'}$. The definition of G is analogous. The square in question then fits into a rectangle

$$\begin{array}{ccccc} \{x\} \times_C C_{/p} & \xrightarrow{F} & C_{/p'} & \longrightarrow & C_{/p} \\ \downarrow & & \downarrow & & \downarrow \\ \{x\} \times_C C_{/p\circ\phi} & \xrightarrow{G} & C_{/p'\circ\phi'} & \longrightarrow & C_{/p\circ\phi} \end{array}$$

where the long horizontal functors are given as the inclusion of the fiber over x and the functors in the righthand square are given by change of diagram. By Prp. 2.11 and left properness of the Joyal model structure, the righthand square is a homotopy pullback square. The vertical functor $C_{/p} \longrightarrow C_{/p\circ\phi}$ is a right fibration, so the outermost square is a homotopy pullback square. The conclusion follows. □

If we want the symmetric promonoidal ∞-category

$$A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^\otimes \longrightarrow \mathrm{N}\Lambda(\mathbf{F})$$

to be symmetric monoidal, we need a nontrivial condition on our disjunctive triple.

2.12. **Definition.** A disjunctive triple $(C, C_\dagger, C^\dagger)$ will be said to be ***cartesian*** just in case it enjoys the following properties

(2.12.1) It is left complete.

(2.12.2) The underlying ∞-category C admits finite products.

(2.12.3) For any object $X \in C$, the product functor

$$X \times -\colon C \longrightarrow C$$

preserves finite coproducts; that is, for any finite set I and any collection $\{U_i \mid i \in I\}$ of objects of C, the natural map

$$\coprod_{i\in I}(X \times U_i) \longrightarrow X \times \left(\coprod_{i\in I} U_i\right)$$

is an equivalence.

(2.12.4) A morphism $X \longrightarrow \prod_{j\in J} Y_j$ is egressive just in case each of the components $X \longrightarrow Y_j$ is so.

2.13. **Example.** Note that a disjunctive ∞-category C that admits a teminal object, when equipped with the maximal triple structure (in which every morphism is both ingressive and egressive) is always cartesian. More generally, any disjunctive triple that contains a terminal object 1 with the property that every morphism $X \longrightarrow 1$ is ingressive and egressive is cartesian.

2.14. **Proposition.** *If $(C, C_\dagger, C^\dagger)$ is a cartesian disjunctive triple, then the symmetric promonoidal ∞-category*

$$p\colon A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^{\otimes} \longrightarrow \mathrm{N}\Lambda(\mathbf{F})$$

is symmetric monoidal; that is, p is a cocartesian fibration.

Proof. Since p is flat, by Pr. 1.5 it suffices to verify that p is a locally cocartesian fibration. Since p is an ∞-operad, by the dual of [16, Lm. 2.4.2.7] we reduce to checking that for any active edge $\alpha\colon I \longrightarrow J$ and any object (I, X) over I, there exists a locally p-cocartesian edge $\widetilde{\alpha}$ covering α. For each $j \in J$, let $\widetilde{X}_j = \prod_{i\in\alpha^{-1}(j)} X_i$, and define $\widetilde{\alpha}$ to be

$$\begin{array}{ccc} & (J, \widetilde{X}) & \\ \swarrow & & \| \\ (I, X) & & (J, \widetilde{X}), \end{array}$$

where the morphism $(J, \widetilde{X}) \longrightarrow (I, X)$ is defined using the various projection maps $\widetilde{X}_{\alpha(i)} \longrightarrow X_i$. Then $\widetilde{\alpha}$ is a locally p-cocartesian edge if for all $(J, Y) \in A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^{\otimes}_J$, the induced map

$$\widetilde{\alpha}^*\colon \mathrm{Map}_{A^{\mathit{eff}}(C,C_\dagger,C^\dagger)^{\otimes}_J}((J, \widetilde{X}), (J, Y)) \longrightarrow \mathrm{Map}_{A^{\mathit{eff}}(C,C_\dagger,C^\dagger)^{\otimes}_\alpha}((I, X), (J, Y))$$

is an equivalence. This map is in turn equivalent to the map

$$\prod_{j\in J} \phi_j\colon \prod_{j\in J} \iota C'_{/\{\prod_{i\in\alpha^{-1}(j)} X_i\ ;\ Y_j\}} \longrightarrow \prod_{j\in J} \iota C'_{/\{X_i\ ;\ Y_j\}_{i\in\alpha^{-1}(j)}}$$

where ϕ_j is induced by postcomposition by the projection maps $\prod_{i\in\alpha^{-1}(j)} X_i \longrightarrow X_i$. Since $(C, C_\dagger, C^\dagger)$ is a cartesian disjunctive triple, we have that the functor

$$(C^\dagger)_{/\prod_{i\in\alpha^{-1}(j)} X_i} \longrightarrow (C^\dagger)_{/(X_i, i\in\alpha^{-1}(j))}$$

is an equivalence. Hence in light of Prp. 2.11 we have a homotopy pullback square

$$\begin{array}{ccc} \prod_{j\in J} \iota C'_{/\{\prod_{i\in\alpha^{-1}(j)} X_i\ ;\ Y_j\}} & \xrightarrow{\phi_j} & \prod_{j\in J} \iota C'_{/\{X_i\ ;\ Y_j\}_{i\in\alpha^{-1}(j)}} \\ \downarrow & & \downarrow \\ (C^\dagger)_{/\prod_{i\in\alpha^{-1}(j)} X_i} & \longrightarrow & (C^\dagger)_{/\{X_i\}_{i\in\alpha^{-1}(j)}} \end{array}$$

where the horizontal maps are equivalences. We deduce that the map $\widetilde{\alpha}^*$ is an equivalence, as desired. ☐

In light of Lm. 2.5 and Rk. 2.7, we obtain the following.

2.15. **Theorem.** *Suppose $(C, C_\dagger, C^\dagger)$ a left complete disjunctive triple. Then the functor*

$$A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^{\otimes} \longrightarrow \mathrm{N}\Lambda(\mathbf{F})$$

exhibits $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^{\otimes}$ as a symmetric promonoidal ∞-category, the underlying ∞-category of which is the effective Burnside ∞-category $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)$. Furthermore, if $(C, C_\dagger, C^\dagger)$ is cartesian, then $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^{\otimes}$ is symmetric monoidal.

2.16. **Notation.** When $(C, C_\dagger, C^\dagger)$ is a *right* complete disjunctive triple, we may employ duality and write

$$A^{\mathit{eff}}(C, C_\dagger, C^\dagger)_{\otimes} := (A^{\mathit{eff}}(C, C^\dagger, C_\dagger)^{\otimes})^{op}.$$

The functor $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)_{\otimes} \longrightarrow \mathrm{N}\Lambda(\mathbf{F})^{op}$ is then a symmetric promonoidal structure on the Burnside ∞-category $A^{\mathit{eff}}(C, C^\dagger, C_\dagger)^{op} \simeq A^{\mathit{eff}}(C, C_\dagger, C^\dagger)$.

2.17. Suppose $(C, C_\dagger, C^\dagger)$ a cartesian disjunctive triple. Note that the formula

$$\coprod_{i \in I}(X \times U_i) \simeq X \times \left(\coprod_{i \in I} U_i\right)$$

implies immediately that the tensor product functor

$$\otimes \colon A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \times A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \longrightarrow A^{\mathit{eff}}(C, C_\dagger, C^\dagger)$$

preserves direct sums separately in each variable.

More generally, suppose $(C, C_\dagger, C^\dagger)$ a left complete disjunctive triple, suppose I a finite set, and suppose $\{x_i\}_{i \in I}$ a collection of objects of C, which we view, by the standard abuse, as an object of $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^{\otimes}_{I}$. Consider the 1-simplex $\xi_I \colon \Delta^1 \longrightarrow N\Lambda(\mathbf{F})$, and denote by $h^{\{x_i\}_{i \in I}}$ the restriction of the functor

$$A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^{\otimes} \times_{N\Lambda(\mathbf{F})} \Delta^1 \longrightarrow \mathbf{Kan}$$

corepresented by $\{x_i\}_{i \in I}$ to $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)$. Informally, this is the functor

$$\mathrm{Map}^{\xi_I}_{C^{\otimes}}(\{x_i\}_{i \in I}, -).$$

Suppose $j \in I$, and suppose $\{y_k \longrightarrow x_j\}_{k \in K}$ a family of morphisms that together exhibit x_j as the coproduct $\coprod_{k \in K} y_k$. For each $i \in I$ and $k \in K$, write

$$x'_{i,k} := \begin{cases} y_k & \text{if } i = j; \\ x_i & \text{if } i \neq j. \end{cases}$$

Then the natural map

$$h^{\{x_i\}_{i \in I}} \longrightarrow \prod_{k \in K} h^{\{x'_{i,k}\}_{i \in I}}$$

is an equivalence.

2.18. For any disjunctive ∞-category C that admits a terminal object, the duality functor

$$D \colon A^{\mathit{eff}}(C)^{op} \xrightarrow{\sim} A^{\mathit{eff}}(C)$$

of [4, Nt. 3.10] provides duals for the symmetric monoidal ∞-category $A^{\mathit{eff}}(C)^{\otimes}$ [17, Df. 2.3.5]. More precisely, for any object X of $A^{\mathit{eff}}(C)$, there exists an evaluation morphism $X \otimes DX \longrightarrow 1$ given by the diagram

$$\begin{array}{ccc} & X & \\ {\scriptstyle\Delta}\swarrow & & \searrow{\scriptstyle !} \\ X \times X & & 1, \end{array}$$

and, dually, there exists a coevaluation morphism $1 \longrightarrow DX \otimes X$ given by the diagram

$$\begin{array}{ccc} & X & \\ {\scriptstyle !}\swarrow & & \searrow{\scriptstyle\Delta} \\ 1 & & X \times X. \end{array}$$

Since the square

$$\begin{array}{ccc} X & \xrightarrow{\Delta} & X \times X \\ {\scriptstyle\Delta}\downarrow & & \downarrow{\scriptstyle\Delta \times \mathrm{id}} \\ X \times X & \xrightarrow[\mathrm{id} \times \Delta]{} & X \times X \times X \end{array}$$

is a pullback, it follows that the composite

$$X \longrightarrow X \otimes DX \otimes X \longrightarrow X$$

in $A^{eff}(C)$ is homotopic to the identity. We conclude that $A^{eff}(C)^{\otimes}$ is a symmetric monoidal ∞-category with duals.

2.19. If $(C, C_{\dagger}, C^{\dagger})$ is a cartesian disjunctive triple, then in general it is not quite the case that the symmetric monoidal ∞-category $A^{eff}(C, C_{\dagger}, C^{\dagger})^{\otimes}$ admits duals. We have an evaluation morphism $X \otimes DX \longrightarrow 1$ in $A^{eff}(C, C_{\dagger}, C^{\dagger})$ just in case the diagonal $\Delta\colon X \longrightarrow X \times X$ of C is egressive, and the morphism $!\colon X \longrightarrow 1$ is ingressive. We have a coevaluation morphism $1 \longrightarrow DX \otimes X$ in $A^{eff}(C, C_{\dagger}, C^{\dagger})$ just in case Δ is ingressive and ! is egressive.

2.20. If $(C, C_{\dagger}, C^{\dagger})$ and $(D, D_{\dagger}, D^{\dagger})$ are left complete disjunctive triples, then it is easy to see that a functor of disjunctive triples

$$f\colon (C, C_{\dagger}, C^{\dagger}) \longrightarrow (D, D_{\dagger}, D^{\dagger})$$

induces a functor of adequate triples

$$(C_{\times}, (C_{\times})_{\dagger}, (C_{\times})^{\dagger}) \longrightarrow (D_{\times}, (D_{\times})_{\dagger}, (D_{\times})^{\dagger})$$

and thus a morphism of ∞-operads

$$A^{eff}(f)^{\otimes}\colon A^{eff}(C, C_{\dagger}, C^{\dagger})^{\otimes} \longrightarrow A^{eff}(D, D_{\dagger}, D^{\dagger})^{\otimes}.$$

If, furthermore, $(C, C_{\dagger}, C^{\dagger})$ and $(D, D_{\dagger}, D^{\dagger})$ are cartesian and f preserves finite products, then $A^{eff}(f)^{\otimes}$ is of course a symmetric monoidal functor.

3. Green functors

Andreas Dress [10] defined Green functors as Mackey functors equipped with certain pairings. Gaunce Lewis [14] noticed that these pairings made them commutative monoids for the Day convolution tensor product on the category of Mackey functors. By an old observation of Brian Day [9, Ex. 3.2.2], these are precisely the lax symmetric monoidal additive functors on the effective Burnside category. Thanks to recent work of Saul Glasman [11], this characterization of monoids for the Day convolution holds in the ∞-categorical context as well.

3.1. **Definition.** We shall say that a symmetric monoidal ∞-category $E^{\otimes}$ is ***additive*** if the underlying ∞-category E is additive, and the tensor product functor $\otimes\colon E \times E \longrightarrow E$ preserves direct sums separately in each variable.

3.2. **Definition.** (3.2.1) Suppose $(C, C_{\dagger}, C^{\dagger})$ a left complete disjunctive triple and $E^{\otimes}$ an additive symmetric monoidal ∞-category. Then a ***commutative Green functor*** is a morphism of ∞-operads

$$A^{eff}(C, C_{\dagger}, C^{\dagger})^{\otimes} \longrightarrow E^{\otimes}$$

such that the underlying functor $A^{eff}(C, C_{\dagger}, C^{\dagger}) \longrightarrow E$ preserves direct sums.

(3.2.2) More generally, if $O^{\otimes}$ is an ∞-operad, then an $O^{\otimes}$***-Green functor*** is a morphism of ∞-operads

$$A^{eff}(C, C_{\dagger}, C^{\dagger})^{\otimes} \times_{\mathrm{N}\Lambda(\mathbf{F})} O^{\otimes} \longrightarrow E^{\otimes} \times_{\mathrm{N}\Lambda(\mathbf{F})} O^{\otimes}$$

over $O^{\otimes}$ such that for any object X of the underlying ∞-category O, the functor

$$A^{eff}(C, C_{\dagger}, C^{\dagger}) \simeq (A^{eff}(C, C_{\dagger}, C^{\dagger})^{\otimes} \times_{\mathrm{N}\Lambda(\mathbf{F})} O^{\otimes})_X \longrightarrow (E^{\otimes} \times_{\mathrm{N}\Lambda(\mathbf{F})} O^{\otimes})_X \simeq E$$

preserves direct sums.

(3.2.3) Similarly, for any perfect operator category Φ, we may define a Φ***-Green functor*** as a morphism

$$A^{eff}(C, C_{\dagger}, C^{\dagger})^{\otimes} \times_{\mathrm{N}\Lambda(\mathbf{F})} \mathrm{N}\Lambda(\Phi) \longrightarrow E^{\otimes} \times_{\mathrm{N}\Lambda(\mathbf{F})} \mathrm{N}\Lambda(\Phi)$$

of ∞-operads over Φ such that the underlying functor $A^{eff}(C, C_{\dagger}, C^{\dagger}) \longrightarrow E$ preserves direct sums.

3.3. **Notation.** Suppose $(C, C_{\dagger}, C^{\dagger})$ a left complete disjunctive triple, and suppose $E^{\otimes}$ an additive symmetric monoidal ∞-category. For any ∞-operad $O^{\otimes}$, let us write, employing the notation of [19, Df. 2.1.3.1]

$$\mathbf{Green}_{O^{\otimes}}(C, C_{\dagger}, C^{\dagger}; E^{\otimes}) \subset \mathbf{Alg}_{A^{eff}(C, C_{\dagger}, C^{\dagger})^{\otimes} \times_{\mathrm{N}\Lambda(\mathbf{F})} O^{\otimes} \ /O^{\otimes}}(E^{\otimes} \times_{\mathrm{N}\Lambda(\mathbf{F})} O^{\otimes})$$

for the full subcategory spanned by the $O^{\otimes}$-Green functors.

3.4. **Example.** We define *modules* over an *associative Green functor* in this way. Suppose $(C, C_{\dagger}, C^{\dagger})$ a left complete disjunctive triple, and suppose $E^{\otimes}$ an additive symmetric monoidal ∞-category. Then we may consider the ∞-operad of [19, Df. 4.2.7], which we will denote $\mathrm{LM}^{\otimes}$. The inclusion $\mathrm{Ass}^{\otimes} \hookrightarrow \mathrm{LM}^{\otimes}$ induces a functor

$$\mathbf{Green}_{\mathrm{LM}^{\otimes}}(C, C_{\dagger}, C^{\dagger}; E^{\otimes}) \longrightarrow \mathbf{Green}_{\mathrm{Ass}^{\otimes}}(C, C_{\dagger}, C^{\dagger}; E^{\otimes}).$$

An object A of the target may be called an ***associative Green functor***, and an object of the fiber of this functor over A may be called a ***left*** A***-module***. We write

$$\mathbf{Mod}^{\ell}_{A}(C, C_{\dagger}, C^{\dagger}; E^{\otimes}) := \mathbf{Green}_{\mathrm{LM}^{\otimes}}(C, C_{\dagger}, C^{\dagger}; E^{\otimes}) \times_{\mathbf{Green}_{\mathrm{Ass}^{\otimes}}(C, C_{\dagger}, C^{\dagger}; E^{\otimes})} \{A\}$$

for the ∞-category of left A-modules. When A is a commutative Green functor, we will drop the superscript ℓ.

The convolution of two Mackey functors will not in general be a Mackey functor, but it can replaced with one by employing a localization (which we might as well call Mackeyification). To prove that convolution followed by Mackeyification defines a symmetric monoidal structure on the ∞-category of Mackey functors, it is necessary to show that Mackeyification is *compatible* with the convolution symmetric monoidal structure in the sense of Lurie [19, Df. 2.2.1.6, Ex. 2.2.1.7].

The following is immediate from [4, Pr. 6.5].

3.5. **Lemma.** *Suppose $(C, C_\dagger, C^\dagger)$ a disjunctive triple, and suppose E a presentable additive ∞-category. Then the ∞-category $\mathbf{Mack}(C, C_\dagger, C^\dagger; E)$ is an accessible localization of the ∞-category $\mathrm{Fun}(A^{\mathit{eff}}(C, C_\dagger, C^\dagger), E)$.*

3.6. **Notation.** Suppose $(C, C_\dagger, C^\dagger)$ a disjunctive ∞-category, and suppose E a presentable additive ∞-category. Then write M for the left adjoint to the fully faithful inclusion

$$\mathbf{Mack}(C, C_\dagger, C^\dagger; E) \hookrightarrow \mathrm{Fun}(A^{\mathit{eff}}(C, C_\dagger, C^\dagger), E).$$

3.7. **Lemma.** *Suppose $(C, C_\dagger, C^\dagger)$ a left complete disjunctive ∞-category, and suppose $E^\otimes$ a presentable symmetric monoidal additive ∞-category. Then the left adjoint M constructed above is compatible in the sense of* [19, Df. 2.2.1.6] *with Glasman's Day convolution symmetric monoidal structure on* $\mathrm{Fun}(A^{\mathit{eff}}(C, C_\dagger, C^\dagger), E)$.

Proof. For any collection of objects $\{s_i \mid i \in I\}$ of C, let

$$h^{\{s_i\}}\colon A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \longrightarrow \mathbf{Kan}$$

be as in 2.17, and for any object $x \in E$, let

$$-\otimes x\colon \mathrm{Fun}(A^{\mathit{eff}}(C, C_\dagger, C^\dagger), \mathbf{Kan}) \longrightarrow \mathrm{Fun}(A^{\mathit{eff}}(C, C_\dagger, C^\dagger), E)$$

be the composition with the tensor product $-\otimes x\colon \mathbf{Kan} \longrightarrow E$ with spaces [16, §4.]. Thus objects of the form $h^{\{s_i\}} \otimes x$ generate the ∞-category $\mathrm{Fun}(A^{\mathit{eff}}(C, C_\dagger, C^\dagger), E)$ under colimits. It is easy to see that for any functors $f, g\colon A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \longrightarrow \mathbf{Kan}$ and any object $x \in E$, the map

$$(f \times g) \otimes x \longrightarrow (f \otimes x) \oplus (g \otimes x)$$

is an M-equivalence; furthermore, the class of M-equivalences is the strongly saturated class generated by the canonical morphisms

$$h^{s\oplus t} \otimes x \longrightarrow (h^s \otimes x) \oplus (h^t \otimes x).$$

This tensor product and the Day convolution are compatible in the sense that there are natural equivalences

$$(h^s \otimes x) \otimes (h^t \otimes y) \simeq h^{\{s,t\}} \otimes (x \otimes y),$$

whence one obtains natural M-equivalences

$$\begin{aligned}
((h^s \otimes x) \oplus (h^t \otimes x)) \otimes (h^u \otimes y) &\simeq ((h^s \otimes x) \otimes (h^u \otimes y)) \oplus ((h^t \otimes x) \otimes (h^u \otimes y)) \\
&\simeq (h^{\{s,u\}} \otimes x \otimes y) \oplus (h^{\{t,u\}} \otimes x \otimes y) \\
&\longrightarrow (h^{\{s,u\}} \times h^{\{t,u\}}) \otimes x \otimes y \\
&\simeq h^{\{s\oplus t,u\}} \otimes x \otimes y \\
&\simeq h^{s\oplus t} \otimes x \otimes h^u \otimes y.
\end{aligned}$$

It follows that for any M-equivalence $X \longrightarrow Y$ and any object Z of the ∞-category $\mathrm{Fun}(A^{\mathit{eff}}(C, C_\dagger, C^\dagger), E)$, the morphism

$$X \otimes Z \longrightarrow Y \otimes Z$$

is an M-equivalence. □

3.8. In particular, if $(C, C_\dagger, C^\dagger)$ is a left complete disjunctive triple, and if $E^\otimes$ a presentable symmetric monoidal additive ∞-category, we obtain a symmetric monoidal ∞-category $\mathbf{Mack}(C, C_\dagger, C^\dagger; E)^\otimes$, and, in light of [11], for any ∞-operad $O^\otimes$, one obtains an equivalence

$$\mathbf{Alg}_{O^\otimes}(\mathbf{Mack}(C, C_\dagger, C^\dagger; E)^\otimes) \simeq \mathbf{Green}_{O^\otimes}(C, C_\dagger, C^\dagger; E).$$

4. Green stabilization

Now let us address the issue of multiplicative structures on the Mackey stabilization, as constructed in [4, §7]. In particular, we aim to show that if E is an ∞-topos, then the Mackey stabilization of a morphism of operads

$$A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^\otimes \longrightarrow E^\times$$

naturally admits the structure of a Green functor

$$A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^\otimes \longrightarrow \mathbf{Sp}(E)^\wedge.$$

4.1. **Definition.** Suppose $(C, C_\dagger, C^\dagger)$ a cartesian disjunctive triple, suppose E an ∞-topos, and suppose

$$f\colon A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^\otimes \longrightarrow E^\times \quad \text{and} \quad F\colon A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^\otimes \longrightarrow \mathbf{Sp}(E)^\otimes$$

morphisms of ∞-operads. Then a morphism of $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^\otimes$-algebras

$$\eta\colon f \longrightarrow \Omega^\infty \circ F$$

will be said to exhibit F as the ***Green stabilization*** of f if F is a Green functor, and if, for any Green functor $R\colon A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^\otimes \longrightarrow \mathbf{Sp}(E)^\otimes$, the map

$$\mathrm{Map}_{\mathbf{Green}_{E_\infty}(C, C_\dagger, C^\dagger; \mathbf{Sp}(E)^\otimes)}(F, R) \longrightarrow \mathrm{Map}_{\mathbf{Alg}_{A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^\otimes}(E^\times)}(f, \Omega^\infty \circ R)$$

induced by η is an equivalence.

The following result is essentially the same as [2, Pr. 2.1].

4.2. **Proposition.** *Suppose $(C, C_\dagger, C^\dagger)$ a cartesian disjunctive triple. There exists a symmetric monoidal ∞-category $\mathrm{D}A(C, C_\dagger, C^\dagger)^\otimes$ and a fully faithful symmetric monoidal functor*

$$j^\otimes\colon A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^\otimes \hookrightarrow \mathrm{D}A(C, C_\dagger, C^\dagger)^\otimes$$

with the following properties.

(4.2.1) The ∞-category $\mathrm{D}A(C, C_\dagger, C^\dagger)$ underlies $\mathrm{D}A(C, C_\dagger, C^\dagger)^\otimes$, and the underlying functor of $j^\otimes$ is the inclusion

$$j\colon A^{\mathit{eff}}(C, C_\dagger, C^\dagger) \hookrightarrow \mathrm{D}A(C, C_\dagger, C^\dagger)$$

of [4, Nt. 7.2].

(4.2.2) *For any symmetric monoidal ∞-category $E^{\otimes}$ whose underlying ∞-category admits all sifted colimits such that the tensor product preserves sifted colimits separately in each variable, the induced functor*

$$\mathbf{Alg}_{\mathrm{D}A(C,C_{\dagger},C^{\dagger})^{\otimes}}(E^{\otimes}) \longrightarrow \mathbf{Alg}_{A^{\mathit{eff}}(C,C_{\dagger},C^{\dagger})^{\otimes}}(E^{\otimes})$$

exhibits an equivalence from the full subcategory spanned by those morphisms of ∞-operads A whose underlying functor $A\colon \mathrm{D}A(C,C_{\dagger},C^{\dagger}) \longrightarrow E$ preserves sifted colimits to the full subcategory spanned by those morphisms of ∞-operads B whose underlying functor $B\colon A^{\mathit{eff}}(C,C_{\dagger},C^{\dagger}) \longrightarrow E$ preserves filtered colimits.

(4.2.3) *The tensor product functor*

$$\otimes\colon \mathrm{D}A(C,C_{\dagger},C^{\dagger}) \times \mathrm{D}A(C,C_{\dagger},C^{\dagger}) \longrightarrow \mathrm{D}A(C,C_{\dagger},C^{\dagger})$$

preserves all colimits separately in each variable.

Proof. The only part that is not a consequence of [19, Pr. 4.8.1.10 and Var. 4.8.1.11] is the assertion that the tensor product functor

$$\otimes\colon \mathrm{D}A(C,C_{\dagger},C^{\dagger}) \times \mathrm{D}A(C,C_{\dagger},C^{\dagger}) \longrightarrow \mathrm{D}A(C,C_{\dagger},C^{\dagger})$$

preserves direct sums separately in each variable. This assertion holds for objects of the effective Burnside category $A^{\mathit{eff}}(C,C_{\dagger},C^{\dagger})$ thanks to the universality of coproducts in C; the general case follows by exhibiting any object of $\mathrm{D}A(C,C_{\dagger},C^{\dagger})$ as a colimit of a sifted diagram of objects of $A^{\mathit{eff}}(C,C_{\dagger},C^{\dagger})$ and using the fact that both the tensor product and the direct sum commute with sifted colimits. ☐

In light of [2, Pr. 3.5] and [19, Pr. 6.2.4.14 and Th. 6.2.6.2], we now have the following.

4.3. **Proposition.** *Suppose $(C,C_{\dagger},C^{\dagger})$ a disjunctive triple, suppose E an ∞-topos, and suppose*

$$f\colon A^{\mathit{eff}}(C,C_{\dagger},C^{\dagger})^{\otimes} \longrightarrow E^{\times}$$

a morphism of ∞-operads. Then a Green stabilization of f exists. In particular, the functor

$$\Omega^{\infty}\circ -\colon \mathbf{Green}(C,C_{\dagger},C^{\dagger};\mathbf{Sp}(E)^{\otimes}) \longrightarrow \mathbf{Alg}_{A^{\mathit{eff}}(C,C_{\dagger},C^{\dagger})^{\otimes}}(E^{\times})$$

admits a left adjoint that covers the left adjoint of the functor

$$\Omega^{\infty}\circ -\colon \mathbf{Mack}(C,C_{\dagger},C^{\dagger};\mathbf{Sp}(E)) \longrightarrow \mathrm{Fun}(A^{\mathit{eff}}(C,C_{\dagger},C^{\dagger}),E).$$

4.4. **Example.** Suppose $(C,C_{\dagger},C^{\dagger})$ a cartesian disjunctive triple. Then the functor

$$A^{\mathit{eff}}(C,C_{\dagger},C^{\dagger}) \longrightarrow \mathbf{Kan}$$

corepresented by the terminal object 1 of C is the unit for the Day convolution symmetric monoidal structure of Glasman, and hence it is an E_{∞} algebra in an essentially unique fashion. Thus we can consider its Green stabilization

$$^{\otimes} = {}^{\otimes}_{(C,C_{\dagger},C^{\dagger})}\colon A^{\mathit{eff}}(C,C_{\dagger},C^{\dagger})^{\otimes} \longrightarrow \mathbf{Sp}^{\wedge},$$

whose underlying Mackey functor is the Burnside Mackey functor $_{(C,C_{\dagger},C^{\dagger})}$ of [4]. We call $^{\otimes}$ the ***Burnside Green functor***.

In a similar vein, we immediately have the following:

4.5. **Proposition.** *For any cartesian disjunctive triple $(C, C_\dagger, C^\dagger)$, the functor*

$$A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^{op} \longrightarrow \mathbf{Mack}(C, C_\dagger, C^\dagger; \mathbf{Sp})$$

given by the assignment $X \rightsquigarrow {}^{X}$ is naturally symmetric monoidal. That is, for any two objects $X, Y \in C$, one has a canonical equivalence

$${}^{X} \otimes {}^{Y} \simeq {}^{X \times Y}$$

4.5.1. **Corollary.** *Suppose $(C, C_\dagger, C^\dagger)$ a cartesian disjunctive triple. For any spectral Mackey functor M thereon, write $F(M, -)$ for the right adjoint to the functor*

$$- \otimes M \colon \mathbf{Mack}(C, C_\dagger, C^\dagger; \mathbf{Sp}) \longrightarrow \mathbf{Mack}(C, C_\dagger, C^\dagger; \mathbf{Sp}).$$

Then for any object $X \in C$, the Mackey functor $F({}^{X}, M)$ is given by the assignment

$$Y \rightsquigarrow M(X \times Y).$$

The following is now immediate.

4.6. **Proposition.** *Suppose $(C, C_\dagger, C^\dagger)$ a cartesian disjunctive triple. The Burnside Mackey functor ${}_{(C, C_\dagger, C^\dagger)}$ is the unit in the symmetric monoidal ∞-category $\mathbf{Mack}(C, C_\dagger, C^\dagger; \mathbf{Sp})^{\otimes}$. Consequently, the Burnside Green functor ${}^{\otimes}_{(C, C_\dagger, C^\dagger)}$ is the initial object in the ∞-category $\mathbf{Green}_{\mathrm{N}\Lambda(\mathbf{F})}(C, C_\dagger, C^\dagger; \mathbf{Sp}^{\otimes})$, and the forgetful functor*

$$\mathbf{Mod}_{\otimes}(C, C_\dagger, C^\dagger; \mathbf{Sp}^{\otimes}) \xrightarrow{\sim} \mathbf{Mack}(C, C_\dagger, C^\dagger; \mathbf{Sp})$$

is an equivalence.

5. Duality

In this section, suppose C a disjunctive ∞-category that admits a terminal object. Since the functor $X \rightsquigarrow {}^{X}$ is symmetric monoidal, it follows immediately that every representable Mackey functor ^{X} is strongly dualizable, and

$$({}^{X})^{\vee} \simeq {}^{DX}$$

5.1. **Notation.** For any associative spectral Green functor R and for any object $X \in C$, denote by R^{X} the left R-module $R \otimes {}^{X}$, and denote by ${}^{X}R$ the right R-module ${}^{X} \otimes R$.

Of course for any left (respectively, right) R-module M, one has

$$\mathrm{Map}(R^{X}, M) \simeq \Omega^{\infty} M(X) \qquad (\text{resp.,} \quad \mathrm{Map}({}^{X}R, M) \simeq \Omega^{\infty} M(X) \quad).$$

5.2. **Definition.** For any associative spectral Green functor R on C, denote by $\mathbf{Perf}^{\ell}_{R}$ the smallest stable subcategory of the ∞-category $\mathbf{Mod}^{\ell}_{R}$ that contains the left R-modules R^{X} (for $X \in C$) and is closed under retracts. Similarly, denote by $\mathbf{Perf}^{r}_{R}$ the smallest stable subcategory of the ∞-category $\mathbf{Mod}^{r}_{R}$ that contains the right R-modules ${}^{X}R$ (for $X \in C$) and is closed under retracts.

The objects of $\mathbf{Perf}^{\ell}_{R}$ (respectively, $\mathbf{Perf}^{r}_{R}$) will be called ***perfect*** left (resp., right) modules over R.

Now we obtain the following, which is a straightforward analogue of [19, Pr. 7.2.5.2].

5.3. **Proposition.** *For any associative spectral Green functor R, a left R-module is compact just in case it is perfect.*

Proof. For any $X \in C$, the functor corepresented by R^X is the assignment $M \rightsquigarrow \Omega^\infty M(X)$, which preserves filtered colimits. Hence R^X is compact, and thus any perfect left R-module is compact.

Conversely, there is a fully faithful, colimit-preserving functor

$$F\colon \mathrm{Ind}(\mathbf{Perf}^\ell_R) \hookrightarrow \mathbf{Mod}_R$$

induced by the inclusion $\mathbf{Perf}^\ell_R \hookrightarrow \mathbf{Mod}^\ell_R$. If this is not essentially surjective, there exists a nonzero left R-module M such that for every R-module N in the essential image of F, the group $[N, M]$ vanishes. In particular, for any integer n and any object $X \in C$,

$$\pi_n M(X) \cong [R^X[n], M] \cong 0,$$

whence $M \simeq 0$. □

The proof of the following is word-for-word identical to that of [19, Pr. 7.2.5.4].

5.4. **Proposition.** *For any associative spectral Green functor R on C, a left R-module M is perfect just in case there exists a right R-module $M^\vee$ that is dual to M in the sense that the functor*

$$\mathrm{Map}(, M^\vee \otimes_R -)\colon \mathbf{Mod}^\ell_R \longrightarrow \mathbf{Kan}$$

is the functor that M corepresents.

5.5. **Example.** Note that, in particular, for any object $X \in C$, one has

$$(R^X)^\vee \simeq {}^{DX}R.$$

6. The Künneth spectral sequence

Let us note that the Künneth spectral sequence works in the Mackey functor context more or less exactly as in the ordinary ∞-category of spectra. To this end, let us first discuss t-structures on ∞-categories of spectral Mackey functors.

6.1. **Proposition.** *Suppose $(C, C_\dagger, C^\dagger)$ a disjunctive triple, and suppose A a stable ∞-category equipped with a t-structure $(A_{\geq 0}, A_{\leq 0})$. Then the two subcategories*

$$\mathbf{Mack}(C, C_\dagger, C^\dagger; A)_{\geq 0} := \mathbf{Mack}(C, C_\dagger, C^\dagger; A_{\geq 0})$$

and

$$\mathbf{Mack}(C, C_\dagger, C^\dagger; A)_{\leq 0} := \mathbf{Mack}(C, C_\dagger, C^\dagger; A_{\leq 0})$$

define a t-structure on $\mathbf{Mack}(C, C_\dagger, C^\dagger; A)$.

Proof. Consider the functor $L\colon \mathbf{Mack}(C, C_\dagger, C^\dagger; A) \longrightarrow \mathbf{Mack}(C, C_\dagger, C^\dagger; A)$ given by composition with $\tau_{\leq -1}$; it is clear that L is a localization functor. Furthermore, the essential image of L is the ∞-category $\mathbf{Mack}(C, C_\dagger, C^\dagger; A_{\leq -1})$, which is closed under extensions, since $A_{\leq -1}$ is. Now we apply [19, Pr. 1.2.1.16]. □

6.2**.** Note that if A a stable ∞-category equipped with a t-structure $(A_{\geq 0}, A_{\leq 0})$, then for any disjunctive triple $(C, C_\dagger, C^\dagger)$, the heart of the induced t-structure on $\mathbf{Mack}(C, C_\dagger, C^\dagger; A)$ is given by

$$\mathbf{Mack}(C, C_\dagger, C^\dagger; A)^\heartsuit \simeq \mathbf{Mack}(C, C_\dagger, C^\dagger; A^\heartsuit).$$

Furthermore, it is clear that many properties of the t-structure on A are inherited by the induced t-structure $\mathbf{Mack}(C, C_\dagger, C^\dagger; A)$: in particular, one verifies easily that the t-structure on $\mathbf{Mack}(C, C_\dagger, C^\dagger; A)$ is left bounded, right bounded, left complete, right complete, compatible with sequential colimits, compatible with filtered colimits, or accessible if the t-structure on A is so.

6.3. **Example.** For any disjunctive triple $(C, C_\dagger, C^\dagger)$, the ∞-category of spectral Mackey functors $\mathbf{Mack}(C, C_\dagger, C^\dagger; \mathbf{Sp})$ admits an accessible t-structure that is both left and right complete whose heart is the abelian category $\mathbf{Mack}(C, C_\dagger, C^\dagger; N\mathbf{Ab})$. Observe that the corepresentable functors $\tau_{\leq 0}{}^X$ are projective objects in the heart, and thus the heart has enough projectives.

In particular, if G is a profinite group and if C is the disjunctive ∞-category of finite G-sets, then the ∞-category $\mathbf{Mack}_G$ of spectral Mackey functors for G admits an accessible t-structure that is both left and right complete, in which the heart $\mathbf{Mack}_G^\heartsuit$ is the nerve of the usual abelian category of Mackey functors for G.

6.4. **Construction.** Suppose A a stable ∞-category equipped with a t-structure. Suppose $(C, C_\dagger, C^\dagger)$ a disjunctive triple, and suppose $X \colon N\mathbf{Z} \longrightarrow \mathbf{Mack}(C, C_\dagger, C^\dagger; A)$ a filtered Mackey functor with colimit $X(+\infty)$. Then we have the spectral sequence

$$E_r^{p,q} := \operatorname{im}\left[\pi_{p+q}\left(\frac{X(p)}{X(p-r)}\right) \longrightarrow \pi_{p+q}\left(\frac{X(p+r-1)}{X(p-1)}\right)\right]$$

associated with X [19, Df. 1.2.2.9].

Note that this is a spectral sequence of $A^\heartsuit$-valued Mackey functors. Since limits and colimits of Mackey functors are defined objectwise, it follows that for any object $U \in A^{eff}(C, C_\dagger, C^\dagger)$, the value $E_r^{p,q}(U)$ is the spectral sequence (in $A^\heartsuit$) associated with the filtered object $X(U) \colon N\mathbf{Z} \longrightarrow A$.

6.5**.** In the setting of Cnstr. 6.4, assume that A admits all sequential colimits and that the t-structure is compatible with these colimits. If $X(n) \simeq 0$ for $n \ll 0$, then the associated spectral sequence converges to a filtration on $\pi_{p+q}(X(+\infty))$ [19, 1.2.2.14]. That is:

- For any p and q, there exists $r \gg 0$ such that the differential
$$d_r \colon E_r^{p,q} \longrightarrow E_r^{p-r,q+r-1}$$
vanishes.
- For any p and q, there exist a discrete, exhaustive filtration
$$\cdots \subset F_{p+q}^{-1} \subset F_{p+q}^{0} \subset F_{p+q}^{1} \subset \cdots \subset \pi_{p+q}X(+\infty)$$
and an isomorphism $E_\infty^{p,q} \cong F_{p+q}^p / F_{p+q}^{p-1}$.

In more general circumstances, one can obtain a kind of "local convergence." Suppose again that A admits all sequential colimits, and that the t-structure is compatible with these colimits. Now suppose that for every object $U \in A^{eff}(C, C_\dagger, C^\dagger)$, there exists $n \ll 0$ such that $X(n)(U) \simeq 0$. Then for every object $U \in A^{eff}(C, C_\dagger, C^\dagger)$, the spectral sequence $E_r^{p,q}(U)$ converges to $\pi_{p+q}(X(+\infty)(U))$. In finitary cases (e.g., when C is the disjunctive ∞-category of finite G-sets for a finite group G), there is no difference between the local convergence and the global convergence.

Better convergence results can be obtained when the filtered Mackey functor is the skeletal filtration of a simplicial connective object Y_* [19, Pr. 1.2.4.5]. In this case, we do not need to assume that the t-structure on A is compatible with sequential colimits, the associated spectral sequence is a first-quadrant spectral sequence, and it converges to a length $p + q$ filtration on $\pi_{p+q}|Y_*|$.

Now, to construct the Künneth spectral sequence for Mackey functors, we can follow very closely the arguments of Lurie [19, §7.2.1].

6.6. **Lemma.** *Suppose $(C, C_\dagger, C^\dagger)$ a disjunctive triple. Then the collection of corepresentable Mackey functors $\{^X \mid X \in A^{eff}(C, C_\dagger, C^\dagger)\}$ is a set of compact projective generators for $\mathbf{Mack}(C, C_\dagger, C^\dagger; \mathbf{Sp}_{\geq 0})$ in the sense of* [16, Dfn. 5.5.2.3].

Proof. The corepresentable functors provide a set of compact projective generators for the ∞-category $\mathrm{Fun}^\times(A^{eff}(C, C_\dagger, C^\dagger), \mathbf{Kan})$ because this category is precisely $P_\Sigma(A^{eff}(C, C_\dagger, C^\dagger)^{op})$. The functor

$$\Omega^\infty \circ -\colon \mathbf{Mack}(C, C_\dagger, C^\dagger; \mathbf{Sp}_{\geq 0}) \longrightarrow \mathrm{Fun}^\times(A^{eff}(C, C_\dagger, C^\dagger), \mathbf{Kan})$$

preserves sifted colimits and is conservative, since $\Omega^\infty\colon \mathbf{Sp}_{\geq 0} \longrightarrow \mathbf{Kan}$ preserves sifted colimits by [19, 1.4.3.9] and is conservative, and the inclusion of both sides into all functors preserves sifted colimits (we use that $\mathbf{Kan}$ is cartesian closed). We conclude by applying [19, 4.7.4.18]. □

To set up the spectral sequence we need to impose the hypotheses of strong dualizability on the ^{X}. Because of this, we now work in the generality of C a disjunctive ∞-category which admits a terminal object.

Suppose

$$R\colon A^{eff}(C)^\otimes \times_{N\Lambda(\mathbf{F})} \mathrm{Ass}^\otimes \longrightarrow \mathbf{Sp}^\wedge \times_{N\Lambda(\mathbf{F})} \mathrm{Ass}^\otimes$$

an associative Green functor, suppose M a right R-module, and suppose N a left R-module. There is a comparison map

$$\mathrm{Tor}_0^{\pi_* R}(\pi_* M, \pi_* N) \longrightarrow \pi_*(M \otimes_R N)$$

constructed as follows: given $x \in \pi_m M(U)$ and $y \in \pi_n N(V)$, choose representatives $\Sigma^m(^U R) \longrightarrow M$ and $\Sigma^n(R^V) \longrightarrow N$ and take their smash product to obtain a map

$$\Sigma^{m+n}(^{U\times V}) \longrightarrow \Sigma^{m+n}(^{U\times V}) \otimes R \simeq \Sigma^m(^U R) \otimes_R \Sigma^n(R^V) \longrightarrow M \otimes_R N$$

and thus an element $x \otimes y \in \pi_{m+n}(M \otimes_R N)(U \times V)$; this is suitably natural so that it descends to a map out of the Day convolution tensor product $\pi_* M \otimes_{\pi_* R} \pi_* N$ to $\pi_*(M \otimes_R N)$. This map is not usually an isomorphism. Instead, we construct a spectral sequence that converges to $\pi_*(M \otimes_R N)$, in which this map appears as an edge homomorphism.

Let S denote the class of left R-modules of the form $\Sigma^n R^X$ for $n \in \mathbf{Z}$ and $X \in C$. By [19, Pr. 7.2.1.4], there exists an S-free S-hypercovering $P_\bullet \longrightarrow N$ in the (presentable) stable ∞-category $\mathbf{Mod}_R^\ell$.

6.7. **Lemma.** *For any S-hypercovering $P_\bullet \longrightarrow N$, we have that $|P_\bullet| \simeq N$.*

Proof. Let $S_{\geq n}$ be the subset of S on $\Sigma^m \circ R^X$ for $m \geq n$. From our S-hypercovering $P_\bullet \longrightarrow N$, we obtain $S_{\geq n}$-hypercoverings $\tau_{\geq n} P_\bullet \longrightarrow \tau_{\geq n} N$ for every $n \in \mathbf{Z}$. Since the $\Sigma^n S^X$, $X \in C$ constitute a set of projective generators for $\mathbf{Mack}(C; \mathbf{Sp}_{\geq n})$ by Lm. 6.6, we have that $|\tau_{\geq n} P_\bullet| \simeq \tau_{\geq n} N$ by the hypercompleteness of $\mathbf{Kan}$. By the right completeness of the t-structure, we deduce that $|P_\bullet| \simeq N$. □

By passing to the skeletal filtration of $M \otimes_R |P_\bullet|$, we obtain a spectral sequence $\{E_r^{p,q}, d_r\}_{r \geq 1}$ that converges to $\pi_{p+q}(M \otimes_R N)$. The complex $(E_1^{*,q}, d_1)$ is the normalized chain complex $N_*(\pi_q(M \otimes_R P_\bullet))$.

To proceed, we need to prove the following analogue of [19, Pr. 7.2.1.17].

6.8. **Lemma.** *If P is a direct sum of objects in S, then the map*

$$\mathrm{Tor}_0^{\pi_* R}(\pi_* M, \pi_* P) \longrightarrow \pi_*(M \otimes_R P)$$

is an isomorphism.

Proof. Both sides commute with direct sums and shifts, so we reduce to the case of $P = R^X$. We claim first that for any spectral Mackey functor E,

$$\pi_* E \otimes \tau_{\leq 0}{}^X \cong \pi_*(E \otimes {}^X).$$

Since $\tau_{\leq 0}{}^Y$ corepresents evaluation at Y for **Ab**-valued Mackey functors, and $\tau_{\leq 0}{}^X$ has dual $\tau_{\leq 0}{}^{DX}$, we have $(\pi_* E \otimes \tau_{\leq 0}{}^X)(Y) \cong (\pi_* E)(Y \times DX)$. Similarly, corepresentability and strong dualizability on the level of the **Sp**-valued Mackey functors implies that $\pi_*(E \otimes {}^X)(Y) \cong (\pi_* E)(Y \times DX)$, so we conclude. Now we apply this claim both for M and R to see that

$$\begin{aligned} \pi_* M \otimes_{\pi_* R} \pi_*(R^X) &\cong \pi_* M \otimes_{\pi_* R} (\pi_* R \otimes \tau_{\leq 0}{}^X) \\ &\cong \pi_* M \otimes \tau_{\leq 0}{}^X \\ &\cong \pi_*(M \otimes {}^X) \\ &\cong \pi_*(M \otimes_R R^X). \end{aligned}$$

We leave the identification of the specified map with this isomorphism to the reader. □

We thus obtain an isomorphism

$$\mathrm{Tor}_0^{\pi_* R}(\pi_* M, \pi_* P_\bullet) \cong \pi_*(M \otimes_R P_\bullet).$$

As $P_\bullet$ is an S-free S-hypercovering of N, $N_*(\pi_* P_\bullet)$ is a resolution of $\pi_* N$ by projective $\pi_* R$-modules. It follows that the E_2 page is given by

$$E_2^{p,q} \cong \mathrm{Tor}_p^{\pi_* R}(\pi_* M, \pi_* N)_q.$$

As in [19, Cor. 7.2.1.23], we have an immediate corollary.

6.8.1. **Corollary.** *Suppose C, R, M, and N as above. Suppose that R, M, and N are all connective. Then $M \otimes_R N$ is connective, and one has an isomorphism of ordinary Mackey functors*

$$\pi_0(M \otimes_R N) \cong \pi_0 M \otimes_{\pi_0 R} \pi_0 N.$$

6.9. **Example.** If C is the category of finite G-sets for G a finite group, then our Künneth spectral sequence recovers that of Lewis and Mandell in [15]. We refer the reader there to a more extensive discussion of this spectral sequence in that particular case.

7. Symmetric monoidal Waldhausen bicartesian fibrations

In [3], we define an $O^\otimes$-monoidal Waldhausen ∞-category for any ∞-operad $O^\otimes$ as an $O^\otimes$-algebra in the symmetric monoidal ∞-category $\mathbf{Wald}_\infty^\otimes$. We give two equivalent fibrational formulations of this notion.

7.1. **Definition.** Suppose $O^\otimes$ an ∞-operad. An ***$O^\otimes$-monoidal Waldhausen ∞-category*** consists of a pair cocartesian fibration [3, Df. 3.8]

$$p^\otimes \colon \mathbf{X}^\otimes \longrightarrow O^\otimes$$

such that the following conditions obtain.

(7.1.1) The composite

$$\mathbf{X}^{\otimes} \longrightarrow O^{\otimes} \longrightarrow \mathrm{N}\Lambda(\mathbf{F})$$

exhibits $\mathbf{X}^{\otimes}$ as an ∞-operad.

(7.1.2) The fiber $p\colon \mathbf{X} \longrightarrow O$ over $* \in \mathrm{N}\Lambda(\mathbf{F})$ is a Waldhausen cocartesian fibration.

(7.1.3) For any finite set I and any choice of inert morphisms $\{\rho_i\colon s \longrightarrow s_i\}_{i\in I}$ covering the inert morphisms $I \longrightarrow \{i\}$, an edge η of $\mathbf{X}^{\otimes}_s$ is ingressive if and only if, for every $i \in I$, the edge $\rho_{i,!}(\eta)$ of $\mathbf{X}_{s_i}$ is ingressive.

(7.1.4) For any finite set I, any morphism $\mu\colon s \longrightarrow t$ of $O^{\otimes}$ covering the unique active morphism $I \longrightarrow \{\xi\}$, and any choice of inert morphisms $\{s \longrightarrow s_i \mid i \in I\}$ covering the inert morphisms $I \longrightarrow \{i\}$, the functor of pairs

$$\mu_!\colon \prod_{i\in I} \mathbf{X}_{s_i} \simeq \mathbf{X}^{\otimes}_s \longrightarrow \mathbf{X}_t$$

is exact separately in each variable [2].

Dually, suppose $O_{\otimes}$ an ∞-anti-operad. Then a ***$O_{\otimes}$-monoidal Waldhausen ∞-category*** is a pair cartesian fibration

$$p_{\otimes}\colon \mathbf{X}_{\otimes} \longrightarrow O_{\otimes}$$

such that the following conditions obtain.

(7.1.5) The composition

$$\mathbf{X}_{\otimes} \longrightarrow O_{\otimes} \longrightarrow \mathrm{N}\Lambda(\mathbf{F})^{op}$$

exhibits $\mathbf{X}_{\otimes}$ as an ∞-anti-operad.

(7.1.6) The fiber $p\colon \mathbf{X} \longrightarrow O$ over $* \in \mathrm{N}\Lambda(\mathbf{F})^{op}$ is a Waldhausen cartesian fibration.

(7.1.7) For any finite set I and any choice of inert morphisms $\{\pi_i\colon s \longrightarrow s_i\}_{i\in I}$ covering the inert morphisms $I \longrightarrow \{i\}$, an edge η of $\mathbf{X}^{\otimes}_s$ is ingressive if and only if, for every $i \in I$, the edge $\pi_i^{\star}(\eta)$ of $\mathbf{X}_{s_i}$ is ingressive.

(7.1.8) For any finite set I, any morphism $\mu\colon t \longrightarrow s$ of $O_{\otimes}$ covering the opposite of the unique active morphism $I \longrightarrow \{\xi\}$, and any choice of inert morphisms $\{s_i \longrightarrow s\}_{i\in I}$ covering the inert morphisms $I \longrightarrow \{i\}$, the functor of pairs

$$\mu^{\star}\colon \prod_{i\in I} \mathbf{X}_{s_i} \simeq \mathbf{X}_{\otimes,s} \longrightarrow \mathbf{X}_t$$

is exact separately in each variable.

Employing [19, Ex. 2.4.2.4 and Pr. 2.4.2.5] and [2, Lm 1.4], one deduces the following.

7.2. **Proposition.** *Suppose $O^{\otimes}$ (respectively, $O_{\otimes}$) an ∞-operad (resp., an ∞-anti-operad). Then the functor*

$$O^{\otimes} \longrightarrow \mathbf{Cat}_{\infty} \qquad \textit{(resp., the functor} \quad (O_{\otimes})^{op} \longrightarrow \mathbf{Cat}_{\infty} \quad \textit{)}$$

classifying an $O^{\otimes}$-monoidal Waldhausen ∞-category (resp., an $O_{\otimes}$-monoidal Waldhausen ∞-category) factors through an essentially unique morphism of ∞-operads

$$O^{\otimes} \longrightarrow \mathbf{Wald}^{\otimes}_{\infty} \qquad \textit{(resp., the functor} \quad (O_{\otimes})^{op} \longrightarrow \mathbf{Wald}^{\otimes}_{\infty} \quad \textit{)}$$

7.3. **Definition.** Now suppose $(C, C_{\dagger}, C^{\dagger})$ a left complete disjunctive triple. A ***symmetric monoidal Waldhausen bicartesian fibration***

$$p_{\boxtimes}\colon \mathbf{X}_{\boxtimes} \longrightarrow C_{\times}$$

over $(C, C_{\dagger}, C^{\dagger})$ is a functor of pairs $\mathbf{X}_{\boxtimes} \longrightarrow (C_{\times})^{\flat}$ with the following properties.

(7.3.1) The underlying functor $p_{\boxtimes}\colon \mathbf{X}_{\boxtimes} \longrightarrow C_{\times}$ is an inner fibration.
(7.3.2) For any egressive morphism $(\phi,\omega) : (I,X) \twoheadrightarrow (J,Y)$ of $C_{\times}$ (in the sense of Nt. 2.1) and for any object Q of the fiber $(\mathbf{X}_{\boxtimes})_{(J,Y)}$, there exists a $p_{\boxtimes}$-cartesian morphism $P \longrightarrow Q$ covering (ϕ,ω).
(7.3.3) The composition

$$\mathbf{X}_{\boxtimes} \longrightarrow C_{\times} \longrightarrow \mathrm{N}\Lambda(\mathbf{F})^{op}$$

exhibits $\mathbf{X}_{\boxtimes}$ as an ∞-anti-operad.
(7.3.4) The fiber $p\colon \mathbf{X} \longrightarrow C$ over $* \in \mathrm{N}\Lambda(\mathbf{F})^{op}$ is a Waldhausen bicartesian fibration $\mathbf{X} \longrightarrow C$ over $(C, C_{\dagger}, C^{\dagger})$.

7.4. This is a lot of data, so let's unpack it a bit.

First, a symmetric monoidal Waldhausen bicartesian fibration

$$p_{\boxtimes}\colon \mathbf{X}_{\boxtimes} \longrightarrow C_{\times}$$

over $(C, C_{\dagger}, C^{\dagger})$ admits an underlying Waldhausen bicartesian fibration $p\colon \mathbf{X} \longrightarrow C$ over $(C, C_{\dagger}, C^{\dagger})$. This provides, for any object $S \in C$, a Waldhausen ∞-category $\mathbf{X}_S$, and for any morphism $\phi\colon S \longrightarrow T$ of C, it provides an exact "pushforward" functor $\phi_!\colon \mathbf{X}_S \longrightarrow \mathbf{X}_T$ whenever ϕ is ingressive and an exact "pullback" functor $\phi^{\star}\colon \mathbf{X}_T \longrightarrow \mathbf{X}_S$ whenever ϕ is egressive. These are compatible with composition, and when ϕ is ingressive and (therefore) egressive, these two are adjoint.

There's more structure here: for any finite set I and any I-tuple $(S_i)_{i\in I}$ of objects of C with product S, consider the cartesian edge

$$(\{\xi\}, S) \longrightarrow (I, S_I)$$

of $C_{\times}$ lying over the morphism $\{\xi\} \longrightarrow I$ of $\Lambda(\mathbf{F})^{op}$ corresponding to the unique active morphism $I \longrightarrow \{\xi\}$ of $\Lambda(\mathbf{F})$; it is of course egressive in $\mathbf{X}_{\boxtimes}$. Hence there is a functor

$$\boxtimes_{i\in I}\colon \prod_{i\in I} \mathbf{X}_{S_i} \longrightarrow \mathbf{X}_S,$$

exact separately in each variable. If $(\phi_i\colon S_i \longrightarrow T_i)_{i\in I}$ is an I-tuple of morphisms of C with product $\phi\colon S \longrightarrow T$ then the square

$$\begin{array}{ccc} \prod_{i\in I} \mathbf{X}_{T_i} & \xrightarrow{\boxtimes_{i\in I}} & \mathbf{X}_T \\ {\scriptstyle \prod_{i\in I}\phi_i^{\star}}\downarrow & & \downarrow{\scriptstyle \phi^{\star}} \\ \prod_{i\in I} \mathbf{X}_{S_i} & \xrightarrow[\boxtimes_{i\in I}]{} & \mathbf{X}_S \end{array}$$

commutes.

When $(C, C_{\dagger}, C^{\dagger})$ is cartesian, this structure endows each fiber $\mathbf{X}_S$ with a symmetric monoidal structure: indeed, for any finite set I, we may define

$$\bigotimes_{i\in I} := \Delta^* \circ \boxtimes_{i\in I},$$

where $\Delta\colon S \longrightarrow S^I$ is the diagonal. One sees easily that the commutativity of the square above implies that any functor $\phi^{\star}$ induced by a morphism $\phi\colon S \longrightarrow T$ is symmetric monoidal in a natural way. Furthermore, a simple argument demonstrates that the external product $\boxtimes_{i\in I}$ can be recovered from the symmetric monoidal structures along with the pullback functors; for example, $X \boxtimes Y \simeq \mathrm{pr}_1^{\star} X \otimes \mathrm{pr}_2^{\star} Y$.

Now it follows from [19, Cor. 7.3.2.7] that if $\phi\colon S \longrightarrow T$ is both ingressive and egressive in C, then $\phi_!$ extends to a lax symmetric monoidal functor $\mathbf{X}_S^{\otimes} \longrightarrow \mathbf{X}_T^{\otimes}$.

7.5. **Lemma.** *Suppose $(C, C_{\dagger}, C^{\dagger})$ a left complete disjunctive triple, and suppose*

$$p_{\boxtimes}\colon \mathbf{X}_{\boxtimes} \longrightarrow C_{\times}$$

a symmetric monoidal Waldhausen bicartesian fibration over $(C, C_{\dagger}, C^{\dagger})$. Then the inner fibration

$$p_{\boxtimes}\colon \mathbf{X}_{\boxtimes} \longrightarrow C_{\times}$$

is an adequate inner fibration [4, Df. 10.3] *for the triple $(C_{\times}, (C_{\times})_{\dagger}, (C_{\times})^{\dagger})$ (Nt. 2.1).*

Proof. The only condition of adequate inner fibrations that isn't explicitly part of the definition above is the assertion that for any ingressive morphism (ϕ, ω) : $(I, X) \rightarrowtail (J, Y)$ of $C_{\times}$ and for any object P of the fiber $(\mathbf{X}_{\boxtimes})_{(I,X)}$, there exists a $p_{\boxtimes}$-cocartesian morphism $P \longrightarrow Q$ covering (ϕ, ω).

So suppose that $(\phi, \omega) : (I, X) \rightarrowtail (J, Y)$ is ingressive — i.e., that $\phi\colon J \longrightarrow I$ is a bijection and each morphism $\omega_{\phi^{-1}(i)}\colon X_i \longrightarrow Y_{\phi^{-1}(i)}$ is ingressive —, and suppose that P is an object of $\mathbf{X}_{\boxtimes}$ that lies over (I, X). Then under the equivalence

$$(\mathbf{X}_{\boxtimes})_I \simeq \prod_{i \in I} \mathbf{X}_{\{i\}},$$

the object P corresponds to a family $(P_i)_{i \in I}$ of objects such that P_i lies over X_i for any $i \in I$. For each $i \in I$, select a p-cocartesian edge $P_i \longrightarrow Q_{\phi^{-1}(i)}$ covering $\omega_{\phi^{-1}(i)}$. Now there is an essentially unique morphism $P \longrightarrow Q$ covering (ϕ, ω) that corresponds under the equivalence above to the edges $P_i \longrightarrow Q_{\phi^{-1}(i)}$, and it is easy to see that it is $p_{\boxtimes}$-cocartesian. ☐

If $(C, C_{\dagger}, C^{\dagger})$ is a left complete disjunctive triple, and if $p_{\boxtimes}\colon \mathbf{X}_{\boxtimes} \longrightarrow C_{\times}$ a symmetric monoidal Waldhausen bicartesian fibration for $(C, C_{\dagger}, C^{\dagger})$, then our goal is now to equip the unfurling of $\mathbf{X}$ with the structure of a $A^{\mathit{eff}}(C)^{\otimes}$-monoidal Waldhausen structure. It will then follow that the corresponding Mackey functor is in fact a commutative Green functor.

7.6. **Construction.** Suppose $(C, C_{\dagger}, C^{\dagger})$ a left complete disjunctive triple, and suppose

$$p_{\boxtimes}\colon \mathbf{X}_{\boxtimes} \longrightarrow C_{\times}$$

a symmetric monoidal Waldhausen bicartesian fibration over $(C, C_{\dagger}, C^{\dagger})$. Then we define $\Upsilon(\mathbf{X}/(C, C_{\dagger}, C^{\dagger}))^{\otimes}$ as the pullback

$$\Upsilon(\mathbf{X}_{\boxtimes}/(C_{\times}, (C_{\times})_{\dagger}, (C_{\times})^{\dagger})) \times_{A^{\mathit{eff}}(C_{\times}, (C_{\times})_{\dagger}, (C_{\times})^{\dagger})} A^{\mathit{eff}}(C, C_{\dagger}, C^{\dagger})^{\otimes}.$$

The inner fibration [4, Lm. 11.4]

$$\Upsilon(\mathbf{X}_{\boxtimes}/(C_{\times}, (C_{\times})_{\dagger}, (C_{\times})^{\dagger})) \longrightarrow A^{\mathit{eff}}(C_{\times}, (C_{\times})_{\dagger}, (C_{\times})^{\dagger})$$

pulls back to an inner fibration

$$\Upsilon(p)^{\otimes}\colon \Upsilon(\mathbf{X}/(C, C_{\dagger}, C^{\dagger}))^{\otimes} \longrightarrow A^{\mathit{eff}}(C, C_{\dagger}, C^{\dagger})^{\otimes}.$$

We call this the ***unfurling*** of the symmetric monoidal Waldhausen bicartesian fibration $p_{\boxtimes}$.

7.7. Suppose, for simplicity, that $(C, C_\dagger, C^\dagger)$ is cartesian. Unwinding the definitions, one sees that the objects of $\Upsilon(\mathbf{X}/(C, C_\dagger, C^\dagger))^\otimes$ are precisely the objects of $\mathbf{X}_\boxtimes$. These, in turn, can be thought of as triples (I, S_I, P_{S_I}) consiting of a finite set I, an I-tuple $S_I := (S_i)_{i\in I}$, and an object P_{S_I} of the fiber

$$(\mathbf{X}_\otimes)_{S_I} \simeq \prod_{i\in I} \mathbf{X}_{S_i},$$

which corresponds to an I-tuple $(P_{S_i})_{i\in I}$ of objects of the various Waldhausen ∞-categories $\mathbf{X}_{S_i}$. Now a morphism $(J, T_J, Q_{T_J}) \longrightarrow (I, S_I, P_{S_I})$ of the unfurling $\Upsilon(\mathbf{X}/(C, C_\dagger, C^\dagger))^\otimes$ can be thought of as the following data:

(7.7.1) a morphism $\phi\colon J \longrightarrow I$ of $\Lambda(\mathbf{F})$;

(7.7.2) a collection of diagrams

$$\left\{ \begin{array}{ccc} & U_{\phi(j)} & \\ {\scriptstyle\tau_j}\swarrow & & \searrow{\scriptstyle\sigma_{\phi(j)}} \\ T_j & & S_{\phi(j)}, \end{array} \;\middle|\; j \in \phi^{-1}(I) \right\}$$

of C such that for any $j \in \phi^{-1}(I)$, the morphism $\sigma_j\colon U_{\phi(j)} \rightarrowtail S_{\phi(j)}$ is ingressive, and the morphism $\tau_j\colon U_{\phi(j)} \twoheadrightarrow T_j$ is egressive; and

(7.7.3) a collection of morphisms

$$\left\{ \sigma_{\phi(j),!}\tau^\star_{J_i}\left(\boxtimes_{j\in J_i} Q_{T_j}\right) \longrightarrow P_{S_i} \;\middle|\; i \in I \right\}$$

in the various ∞-categories $\mathbf{X}_{S_i}$, where τ_{J_i} is the edge $(\{i\}, U_i) \longrightarrow (J_i, T_{J_i})$ corresponding to the tuple $(\tau_j)_{j\in J_i}$.

7.8. **Theorem.** *Suppose $(C, C_\dagger, C^\dagger)$ a left complete disjunctive triple, and suppose*

$$p_\boxtimes\colon \mathbf{X}_\boxtimes \longrightarrow C_\times$$

a symmetric monoidal Waldhausen bicartesian fibration over $(C, C_\dagger, C^\dagger)$. Then the functor $\Upsilon(p)^\otimes$ exhibits the ∞-category $\Upsilon(\mathbf{X}/(C, C_\dagger, C^\dagger))^\otimes$ as a $A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^\otimes$-monoidal Waldhausen ∞-category.

Proof. We first observe that, in light of [4, Pr. 11.6] and Lm. 7.5, the functor $\Upsilon(p)^\otimes$ is a cocartesian fibration. Let us check that the composite cocartesian fibration

$$\Upsilon(\mathbf{X}/(C, C_\dagger, C^\dagger))^\otimes \longrightarrow A^{\mathit{eff}}(C, C_\dagger, C^\dagger)^\otimes \longrightarrow \mathrm{N}\Lambda(\mathbf{F})$$

exhibits $\Upsilon(\mathbf{X}/(C, C_\dagger, C^\dagger))^\otimes$ as a symmetric monoidal ∞-category.

To this end, it suffices to show that for any finite set I and any I-tuple $S_I := (S_i)_{i\in I}$ of objects of C, the functor

$$\prod_{i\in I}\chi_{i,!}\colon (\mathbf{X}_\boxtimes)_{S_I} \simeq \Upsilon(\mathbf{X}/(C, C_\dagger, C^\dagger))^\otimes_{S_I} \longrightarrow \prod_{i\in I}\Upsilon(\mathbf{X}/(C, C_\dagger, C^\dagger))_{S_i} \simeq \prod_{i\in I}\mathbf{X}_{S_i}$$

induced by the cocartesian edges covering the inert maps $\chi_i\colon I \longrightarrow \{i\}_+$ is an equivalence. But this morphism can be identified with

$$\prod_{i\in I}\left(\mathrm{id}_! \circ \mathrm{id}^\star \circ \boxtimes_{i\in\{i\}}\right) \colon \prod_{i\in I}\mathbf{X}_{S_i} \longrightarrow \prod_{i\in I}\mathbf{X}_{S_i},$$

which is homotopic to the identity.

Now for any finite set J, a morphism $T \longrightarrow S$ of $A^{eff}(C, C_\dagger, C^\dagger)^\otimes$ covering the unique active morphism $J \longrightarrow \{\xi\}$ is represented by a collection of spans

$$\left\{ \begin{array}{ccc} & U & \\ {}^{\phi_j}\swarrow & & \searrow^{\psi} \\ T_j & & S. \end{array} \;\middle|\; j \in J \right\}$$

The tensor product functor can therefore be written as

$$\psi_! \circ \phi_J^\star \circ \boxtimes_{j\in J} \colon \prod_{j\in J} \mathbf{X}_{T_j} \simeq \mathbf{X}_T \longrightarrow \mathbf{X}_S,$$

which is exact separately in each variable. □

In light of Pr. 7.2, we have the following.

7.8.1. **Corollary.** *Suppose $(C, C_\dagger, C^\dagger)$ a cartesian disjunctive triple that is either left complete or right complete, and suppose $p_\boxtimes \colon \mathbf{X}_\boxtimes \longrightarrow C_\times$ a symmetric monoidal Waldhausen bicartesian fibration over $(C, C_\dagger, C^\dagger)$. Then the cocartesian fibration $\Upsilon(p)^\otimes$ is classified by a Green functor*

$$\mathbf{M}_p^\otimes \colon A^{eff}(C, C_\dagger, C^\dagger)^\otimes \longrightarrow \mathbf{Wald}_\infty^\otimes.$$

8. Equivariant algebraic K-theory of group actions

In this section, we answer a question of Akhil Mathew. Namely, for any Waldhausen ∞-category C with an action of a finite group G, can one form an equivariant algebraic K-theory spectrum $K_G(C)$ whose H-fixed point spectrum is the algebraic K-theory of the homotopy fixed point ∞-category C^{hH}? Furthermore, can one do this in a lax symmetric monoidal fashion, so that if C is an algebra in Waldhausen ∞-categories over an ∞-operad $O^\otimes$, then $K_G(C)$ is an algebra over $O^\otimes$ in $\mathbf{Mack}(\mathbf{F}_G; \mathbf{Sp})$? The answer to both of these questions is yes, and our framework makes it an almost trivial matter to see how.

8.1. **Construction.** Suppose G a finite group. Let denote by $\mathbf{F}_G^{free} \subset \mathbf{F}_G$ the full subcategory spanned by those finite G-sets upon which G acts freely. Observe that $\mathbf{F}_G^{free}$ is the finite-coproduct completion of BG; that is, it is the free ∞-category with finite coproducts generated by BG. Consequently, $A^{eff}(\mathbf{F}_G^{free})$ is the free semiadditive ∞-category generated by BG; that is, evaluation at G/e defines an equivalence

$$\mathbf{Mack}(\mathbf{F}_G^{free}; A) \xrightarrow{\sim} \mathrm{Fun}(BG, A).$$

At the same time, the subcategory $\mathbf{F}_G^{free} \subset \mathbf{F}_G$ is clearly closed under coproducts, and since $\mathbf{F}_G^{free}$ is a sieve in $\mathbf{F}_G$, it follows that it is stable under pullbacks and binary products as well. Consequently, we obtain a fully faithful inclusion

$$A^{eff}(\mathbf{F}_G^{free}) \hookrightarrow A^{eff}(\mathbf{F}_G).$$

We thus obtain, for any semiadditive ∞-category A, a corresponding restriction functor

$$\mathbf{Mack}(\mathbf{F}_G; A) \longrightarrow \mathbf{Mack}(\mathbf{F}_G^{free}; A).$$

If A is an addition presentable, then the restriction functor admits a right adjoint

$$B_G \colon \mathrm{Fun}(BG, A) \longrightarrow \mathbf{Mack}(\mathbf{F}_G; A),$$

given by right Kan extension. We shall call this the *Borel functor*, since it assigns to any "naïve" G-object the corresponding *Borel-equivariant* object.

Applying this when $A = \mathbf{Wald}_\infty$ and apply algebraic K-theory, we obtain the *algebraic K-theory of group actions*:

$$\mathbf{K} \circ B_G \colon \mathrm{Fun}(BG, \mathbf{Wald}_\infty) \longrightarrow \mathbf{Mack}(\mathbf{F}_G; \mathbf{Sp}).$$

8.2. **Proposition.** *The algebraic K-theory of group actions extends naturally to a lax symmetric monoidal functor*

$$\mathbf{K}^{\otimes} \circ B_G^{\otimes} \colon \mathrm{Fun}(BG, \mathbf{Wald}_\infty)^{\otimes} \longrightarrow \mathbf{Mack}(\mathbf{F}_G; \mathbf{Sp})^{\otimes}.$$

for the objectwise symmetric monoidal structure relative to the symmetric monoidal structure on $\mathbf{Wald}_\infty$ [2] *and the additivized Day convolution on spectral Mackey functors.*

Proof. Since $\mathbf{K}^{\otimes}$ is lax symmetric monoidal [2], it suffices to show that for any presentable semiadditive symmetric monoidal ∞-category $E^{\otimes}$, the Borel functor B_G extends to a symmetric monoidal functor

$$B_G^{\otimes} \colon \mathrm{Fun}(BG, E)^{\otimes} \simeq \mathbf{Mack}(\mathbf{F}_G^{\mathit{free}}; A)^{\otimes} \longrightarrow \mathbf{Mack}(\mathbf{F}_G; E)^{\otimes}.$$

This will follow directly from [19], once one knows that the restriction functor

$$\mathbf{Mack}(\mathbf{F}_G; E) \longrightarrow \mathrm{Fun}(BG, E)$$

extends to a symmetric monoidal functor

$$\mathbf{Mack}(\mathbf{F}_G; E)^{\otimes} \longrightarrow \mathbf{Mack}(\mathbf{F}_G^{\mathit{free}}; A)^{\otimes} \simeq \mathrm{Fun}(BG, E)^{\otimes}.$$

For this, observe that since $\mathbf{F}_G^{\mathit{free}} \subset \mathbf{F}_G$ is stable under binary products, the inclusion

$$A^{\mathit{eff}}(\mathbf{F}_G^{\mathit{free}}) \hookrightarrow A^{\mathit{eff}}(\mathbf{F}_G)$$

extends to a symmetric monoidal functor

$$A^{\mathit{eff}}(\mathbf{F}_G^{\mathit{free}})^{\otimes} \hookrightarrow A^{\mathit{eff}}(\mathbf{F}_G)^{\otimes}.$$

It thus suffices to note that for any free finite G-set V, the subcategory

$$(A^{\mathit{eff}}(\mathbf{F}_G^{\mathit{free}}) \times A^{\mathit{eff}}(\mathbf{F}_G^{\mathit{free}})) \times_{A^{\mathit{eff}}(\mathbf{F}_G^{\mathit{free}})} A^{\mathit{eff}}(\mathbf{F}_G^{\mathit{free}})_{/V} \subset (A^{eff}(\mathbf{F}_G) \times A^{\mathit{eff}}(\mathbf{F}_G)) \times_{A^{\mathit{eff}}(\mathbf{F}_G)} A^{\mathit{eff}}(\mathbf{F}_G)_{/V}$$

is cofinal. □

9. Equivariant algebraic K-theory of derived stacks

In this section, we construct two symmetric monoidal Waldhausen bicartesian fibrations that extend the following two Waldhausen bicartesian fibrations introduced in [4, §D]:

- the Waldhausen bicartesian fibration

  $$\mathbf{Perf}^{op} \times_{\mathbf{Shv}_{\mathit{flat}}} \mathbf{DM} \longrightarrow \mathbf{DM}$$

  for the left complete disjunctive triple $(\mathbf{DM}, \mathbf{DM}_{\mathbf{FP}}, \mathbf{DM})$ of spectral Deligne–Mumford stacks, in which the ingressive morphisms are strongly proper morphisms of finite Tor-amplitude, and all morphisms are egressive [4, Pr. D.18], and

- the Waldhausen bicartesian fibration

$$\mathbf{Perf}^{op} \longrightarrow \mathbf{Shv}_{flat}$$

for the left complete disjunctive triple $(\mathbf{Shv}_{flat}, \mathbf{Shv}_{flat,\mathbf{QP}}, \mathbf{Shv}_{flat})$ of flat sheaves in which the ingressive morphisms are the quasi-affine representable and perfect morphisms, and all morphisms are egressive [4, Pr. D.21].

These will give algebraic K-theory the structure of a commutative Green functor for these two triples.

9.1. To begin, we let

$$\begin{array}{ccc} \mathbf{Mod}^{\otimes} & \longrightarrow & \mathbf{QCoh}^{\otimes} \\ {\scriptstyle q}\downarrow & & \downarrow{\scriptstyle p} \\ \mathbf{CAlg}^{cn} \times N\Lambda(\mathbf{F}) & \hookrightarrow & \mathbf{Shv}^{op}_{flat} \times N\Lambda(\mathbf{F}) \end{array}$$

be a pullback square in which q is the cocartesian fibration of [19, Th. 4.5.3.1], and p is a cocartesian fibration classified by the right Kan extension of the functor that classifies q. The objects of $\mathbf{QCoh}^{\otimes}$ can be thought of as triples (X, I, M_I) consisting of a sheaf $X\colon \mathbf{CAlg}^{cn} \longrightarrow \mathbf{Kan}(\kappa_1)$ for the flat topology, a finite set I, and an I-tuple $M_I = \{M_i\}_{i\in I}$ of quasicoherent modules M over X.

9.2. We may now pass to the cocartesian ∞-operads to obtain a cocartesian fibration of ∞-operads

$$p^{\sqcup}\colon (\mathbf{QCoh}^{\otimes})^{\sqcup} \longrightarrow (\mathbf{Shv}^{op}_{flat} \times N\Lambda(\mathbf{F}))^{\sqcup} \simeq (\mathbf{Shv}_{flat,\times})^{op} \times_{N\Lambda(\mathbf{F})} N\Lambda(\mathbf{F})^{\sqcup}.$$

Now $N\Lambda(\mathbf{F})^{\sqcup} \longrightarrow N\Lambda(\mathbf{F})$ admits a section that carries any finite set I to the pair $(I, *_I)$, where $*_I = \{*\}_{i\in I}$. Let us pull back $p^{\sqcup}$ along this section to obtain a cocartesian fibration of ∞-operads

$$p^{\boxtimes}\colon \mathbf{QCoh}^{\boxtimes} := (\mathbf{QCoh}^{\otimes})^{\sqcup} \times_{N\Lambda(\mathbf{F})^{\sqcup}} N\Lambda(\mathbf{F}) \longrightarrow (\mathbf{Shv}_{flat,\times})^{op}.$$

9.3. Passing to opposites, we obtain a functor

$$(\mathbf{QCoh}^{op})_{\boxtimes} := (\mathbf{QCoh}^{\boxtimes})^{op} \longrightarrow \mathbf{Shv}_{flat,\times}$$

which

- restricts to a symmetric monoidal Waldhausen bicartesian fibration

$$(\mathbf{QCoh}^{op})_{\boxtimes} \times_{\mathbf{Shv}_{flat,\times}} \mathbf{DM}_{\times} \longrightarrow \mathbf{DM}_{\times}$$

that extends the Waldhausen bicartesian fibration of [4, Pr. D.10] for the disjunctive triple of spectral Deligne–Mumford stacks, in which the ingressive morphisms are relatively scalloped, and all morphisms are egressive, and

- gives a symmetric monoidal Waldhausen bicartesian fibration

$$(\mathbf{QCoh}^{op})_{\boxtimes} \longrightarrow \mathbf{Shv}_{flat,\times}$$

that extends the Waldhausen bicartesian fibration of [4, Pr. D.13] for the disjunctive triple of flat sheaves, in which the ingressive morphisms are quasi-affine representable, and all morphisms are egressive.

9.4. At last, restricting to perfect modules, we obtain the desired symmetric monoidal Waldhausen bicartesian fibrations

$$(\mathbf{Perf}^{op})_{\boxtimes} \times_{(\mathbf{Shv}_{flat})_{\times}} \mathbf{DM}_{\times} \longrightarrow \mathbf{DM}_{\times}$$

for $(\mathbf{DM}, \mathbf{DM}_{\mathbf{FP}}, \mathbf{DM})$ and

$$(\mathbf{Perf}^{op})_{\boxtimes} \longrightarrow (\mathbf{Shv}_{flat})_{\times}$$

for $(\mathbf{Shv}_{flat}, \mathbf{Shv}_{flat,\mathbf{QP}}, \mathbf{Shv}_{flat})$.

Now, passing to the unfurling, we obtain the following pair of results.

9.5. **Proposition.** *The Mackey functor*

$$\mathbf{M}_{\mathbf{DM}} \colon A^{eff}(\mathbf{DM}, \mathbf{DM}_{\mathbf{FP}}, \mathbf{DM}) \longrightarrow \mathbf{Wald}_{\infty}$$

of [4, Cor. D.18.1] *admits a natural structure of a commutative Green functor* $\mathbf{M}^{\otimes}_{\mathbf{DM}}$. *In particular, the algebraic K-theory of spectral Deligne–Mumford stacks is naturally a commutative spectral Green functor for* $(\mathbf{DM}, \mathbf{DM}_{\mathbf{FP}}, \mathbf{DM})$.

9.6. **Proposition.** *The Mackey functor*

$$\mathbf{M}_{\mathbf{Shv}_{flat}} \colon A^{eff}(\mathbf{Shv}_{flat}, \mathbf{Shv}_{flat,\mathbf{QP}}, \mathbf{Shv}_{flat}) \longrightarrow \mathbf{Wald}_{\infty}$$

of [4, Cor. D.21.1] *admits a natural structure of a commutative Green functor* $\mathbf{M}^{\otimes}_{\mathbf{Shv}_{flat}}$. *In particular, the algebraic K-theory of flat sheaves is naturally a commutative spectral Green functor for* $(\mathbf{Shv}_{flat}, \mathbf{Shv}_{flat,\mathbf{QP}}, \mathbf{Shv}_{flat})$.

9.7. **Construction.** Suppose X a spectral Deligne–Mumford stack. As in [4, Nt. D.23], we denote by $\mathbf{F\acute{E}t}(X)$ the subcategory of $\mathbf{DM}_{/X}$ whose objects are finite [18, Df. 3.2.4] and étale morphisms $Y \longrightarrow X$ and whose morphisms are finite and étale morphisms over X. Observe that the fiber product $- \times_X -$ endows $\mathbf{F\acute{E}t}(X)$ with the structure of a cartesian disjunctive ∞-category. We will abuse notation and write $A^{eff}(X)^{\otimes}$ for the symmetric monoidal effective Burnside ∞-category of $\mathbf{F\acute{E}t}(X)$.

Now the inclusion

$$(\mathbf{F\acute{E}t}(X), \mathbf{F\acute{E}t}(X), \mathbf{F\acute{E}t}(X)) \hookrightarrow (\mathbf{DM}, \mathbf{DM}_{\mathbf{FP}}, \mathbf{DM})$$

is clearly a morphism of cartesian disjunctive triples, whence one can restrict the commutative Green functor $\mathbf{M}^{\otimes}_{\mathbf{DM}}$ above along the morphism of ∞-operads

$$A^{eff}(X)^{\otimes} \longrightarrow A^{eff}(\mathbf{DM}, \mathbf{DM}_{\mathbf{FP}}, \mathbf{DM})^{\otimes}$$

to a commutative Green functor

$$\mathbf{M}_X \colon A^{eff}(X)^{\otimes} \longrightarrow \mathbf{Wald}^{\otimes}_{\infty}.$$

Now if X is (say) a connected, noetherian scheme, then a choice of geometric point x of X gives rise to an equivalence

$$A^{eff}(\pi_1^{\acute{e}t}(X,x))^{\otimes} \simeq A^{eff}(X)^{\otimes}.$$

Applying algebraic K-theory, we obtain a commutative spectral Green functor for the étale fundamental group:

$$\mathbf{K}^{\otimes}_{\pi_1^{\acute{e}t}(X,x)}(X) \colon A^{eff}(\pi_1^{\acute{e}t}(X,x))^{\otimes} \longrightarrow \mathbf{Sp}^{\otimes}.$$

This commutative Green functor deserves the handle *Galois-equivariant algebraic K-theory*.

10. An equivariant Barratt–Priddy–Quillen Theorem

10.1. **Notation.** In this section, suppose $(C, C_\dagger, C^\dagger)$ a cartesian disjunctive triple.

10.2. **Recollection.** Recall [4, Df. 13.5] that $\mathbf{R}(C) \subset \mathrm{Fun}(\Delta^2/\Delta^{\{0,2\}}, C)$ is the full subcategory spanned by those retract diagrams

$$S_0 \longrightarrow S_1 \longrightarrow S_0;$$

such that the morphism $S_0 \longrightarrow S_1$ is a summand inclusion. We endow $\mathbf{R}(C)$ with the structure of a pair in the following manner. A morphism $T \longrightarrow S$ will be declared ingressive just in case $T_0 \longrightarrow S_0$ is an equivalence, and $T_1 \longrightarrow S_1$ is a summand inclusion. Write p for the functor $\mathbf{R}(C) \longrightarrow C$ given by evaluation at the vertex $0 = 2$:

$$[S_0 \longrightarrow S_1 \longrightarrow S_0] \rightsquigarrow S_0.$$

Recall also that $\mathbf{R}(C, C_\dagger, C^\dagger) \subset \mathbf{R}(C)$ is the full subcategory spanned by those objects

$$S \colon \Delta^2/\Delta^{\{0,2\}} \longrightarrow C$$

such that for any complement $S_0' \hookrightarrow S_1$ of the summand inclusion $S_0 \hookrightarrow S_1$,

(10.2.1) the essentially unique morphism $S_0' \longrightarrow 1$ to the terminal object of C is egressive, and

(10.2.2) the composite $S_0' \longrightarrow S_1 \longrightarrow S_0$ is ingressive.

We endow $\mathbf{R}(C, C_\dagger, C^\dagger)$ with the pair structure induced by $\mathbf{R}(C)$. We will abuse notation by denoting the restriction of the functor $p \colon \mathbf{R}(C) \longrightarrow C$ to the subcategory $\mathbf{R}(C, C_\dagger, C^\dagger) \subset \mathbf{R}(C)$ again by p.

We proved in [4, Th. 13.11] that p is a Waldhausen bicartesian fibration over $(C, C_\dagger, C^\dagger)$.

10.3. **Construction.** Recall that an object of the ∞-category $\mathbf{R}(C, C_\dagger, C^\dagger)_\times$ can be described as pairs (I, X) consisting of a finite set I and a collection $X = \{X_i \mid i \in I\}$ of objects of $\mathbf{R}(C, C_\dagger, C^\dagger)$ indexed by the elements of I. Accordingly, a morphism $(I, X) \longrightarrow (J, Y)$ of $\mathbf{R}(C, C_\dagger, C^\dagger)_\times$ can be described as a map $J \longrightarrow I_+$ of finite sets and a collection

$$\left\{ X_i \longrightarrow \prod_{j \in J_i} Y_j \;\middle|\; i \in I \right\}$$

of morphisms of $\mathbf{R}(C, C_\dagger, C^\dagger)$.

We now define a subcategory $\mathbf{R}(C, C_\dagger, C^\dagger)_\boxtimes \subset \mathbf{R}(C, C_\dagger, C^\dagger)_\times$ that contains all the objects. A morphism $(I, X) \longrightarrow (J, Y)$ of $\mathbf{R}(C, C_\dagger, C^\dagger)_\times$ is a morphism of $\mathbf{R}(C, C_\dagger, C^\dagger)_\boxtimes$ if and only if, for every $i \in I$, every nonempty proper subset $K_i \subset J_i$, and every choice of a complement $Y_{j,0}' \hookrightarrow Y_{j,1}$ of the summand inclusion $Y_{j,0} \hookrightarrow Y_{j,1}$, the square

$$\begin{array}{ccc} \varnothing & \longrightarrow & X_{i,1} \\ \downarrow & & \downarrow \\ \prod_{j \in K_i} Y_{j,0} \times \prod_{j \in J_i \setminus K_i} Y_{j,0}' & \longrightarrow & \prod_{j \in J_i} Y_{j,1}, \end{array}$$

in which $\varnothing$ is initial and the bottom morphism is the obvious summand inclusion, is a pullback.

Let us endow this ∞-category with a pair structure in the following manner. We declare a morphism $(I,X)\longrightarrow(J,Y)$ of $\mathbf{R}(C,C_\dagger,C^\dagger)_\boxtimes$ to be ingressive just in case the map $J\longrightarrow I_+$ represents an isomorphism in $\Lambda(\mathbf{F})$, and, for every $i\in I$, the map $X_i\longrightarrow Y_{\phi(i)}$ of $\mathbf{R}(C,C_\dagger,C^\dagger)$ is ingressive.

The following is now immediate.

10.4. **Proposition.** *The functor*

$$p_\boxtimes\colon \mathbf{R}(C,C_\dagger,C^\dagger)_\boxtimes\longrightarrow C_\times$$

given by evaluation at $0=2$ *in* $\Delta^2/\Delta^{\{0,2\}}$ *exhibits* $\mathbf{R}(C,C_\dagger,C^\dagger)$ *as a symmetric monoidal Waldhausen bicartesian fibration over* $(C,C_\dagger,C^\dagger)$.

10.5. **Construction.** Now we may the unfurling construction of [4, §11] to the symmetric monoidal Waldhausen bicartesian fibration $p_\boxtimes$ to obtain an $A^{eff}(C,C_\dagger,C^\dagger)^\otimes$-monoidal Waldhausen ∞-category (in the sense of [2])

$$\Upsilon(p)^\otimes\colon \Upsilon(\mathbf{R}(C,C_\dagger,C^\dagger)/(C,C_\dagger,C^\dagger))^\otimes\longrightarrow A^{eff}(C,C_\dagger,C^\dagger)^\otimes.$$

As we've demonstrated, $\Upsilon(p)^\otimes$ is classified by an E_∞ Green functor

$$\mathbf{M}_p^\otimes\colon A^{eff}(C,C_\dagger,C^\dagger)^\otimes\longrightarrow \mathbf{Wald}_\infty^\otimes$$

whose underlying functor is the Mackey functor

$$\mathbf{M}_p\colon A^{eff}(C,C_\dagger,C^\dagger)\longrightarrow \mathbf{Wald}_\infty$$

corresponding to the unfurling of the Waldhausen bicartesian fibration

$$\mathbf{R}(C,C_\dagger,C^\dagger)\longrightarrow C$$

over $(C,C_\dagger,C^\dagger)$.

In [2], we demonstrated that algebraic K-theory lifts in a natural fashion to a morphism of ∞-operads, whence we may contemplate the commutative Green functor

$$\mathbf{K}^\otimes\circ\mathbf{M}_p^\otimes\colon A^{eff}(C,C_\dagger,C^\dagger)^\otimes\longrightarrow \mathbf{Sp}^\otimes.$$

Observe that by [4, Th. 13.12], the underlying Mackey functor

$$_{(C,C_\dagger,C^\dagger)} := \mathbf{K}\circ\mathbf{M}_p$$

of $\mathbf{K}^\otimes\circ\mathbf{M}_p^\otimes$ is the spectral Burnside Mackey functor for $(C,C_\dagger,C^\dagger)$, as defined in [4, Df. 8.1]. In particular, it is unit for the symmetric monoidal ∞-category $\mathbf{Mack}(C,C_\dagger,C^\dagger;\mathbf{Sp})$, which of course admits an essentially unique E_∞ structure. Consequently, we deduce the following.

10.6. **Theorem** (Equivariant Barratt–Priddy–Quillen)**.** *The Green functor* $\mathbf{K}^\otimes\circ\mathbf{M}_p^\otimes$ *is the spectral Burnside Green functor* $_{(C,C_\dagger,C^\dagger)}$.

Of course, this result directly implies the original Barratt–Priddy–Quillen Theorem, which states that the algebraic K-theory of the ordinary Waldhausen category $\mathbf{F}_*$ of pointed finite sets (in which the cofibrations are the monomorphisms) is the sphere spectrum . Furthermore, the essentially unique E_∞ structure on is induced by the smash product of pointed finite sets.

11. A brief epilogue about the Theorems of Guillou–May

Suppose G a finite group. Write $\mathbf{OrthSp}_G$ for the underlying ∞-category of the relative category of orthogonal G-spectra. The Equivariant Barratt–Priddy–Quillen Theorem of Guillou–May [12] provides a similar description in $\mathbf{OrthSp}_G$ of certain mapping spectra. Note that this is not *a priori* related to Th. 10.6 when $C = \mathbf{F}_G$. Nevertheless, a suitable comparison theorem (which of course Guillou–May provide in [13]) offers an implication.

On the other hand, the proof of our result here, combined with work from our forthcoming book [6], will allow us to reprove, using entirely different methods, the comparison result of Guillou–May. Indeed, if we can extend the functor $\Sigma^\infty_+ \colon \mathbf{F}_G \longrightarrow \mathbf{OrthSp}_G$ to a suitable functor $A^{\mathit{eff}}(\mathbf{F}_G) \longrightarrow \mathbf{OrthSp}_G$, then the Equivariant Barratt–Priddy–Quillen Theorem above and the Schwede–Shipley theorem [20] together will imply the result of Guillou–May [13] providing the equivalence

$$\mathbf{Sp}^G \simeq \mathbf{OrthSp}_G.$$

It is, however, difficult to construct the desired functor $A^{\mathit{eff}}(\mathbf{F}_G) \longrightarrow \mathbf{OrthSp}_G$ directly, as this involves nontrivial homotopy coherence problems. However, in the language of G-equivariant ∞-category theory, which we develop in the forthcoming [6] provides a universal property for the G-equivariant effective Burnside ∞-category. This will provide us with the desired functor, and we will easily deduce the desired equivalence as a corollary.

PARAMETRIZED HIGHER CATEGORY THEORY AND HIGHER ALGEBRA: A GENERAL INTRODUCTION

CLARK BARWICK, EMANUELE DOTTO, SAUL GLASMAN, DENIS NARDIN, AND JAY SHAH

Let k denote a field, and let $E \supseteq k$ be a finite Galois extension thereof with Galois group G. The algebraic K-groups $K_n(k)$ and $K_n(E)$, as defined by Quillen, together exhibit some interesting structure. Since these groups are defined in terms of the categories of finite-dimensional vector spaces (along with their additive structure), the forgetful functor $\mathbf{Vect}(E) \longrightarrow \mathbf{Vect}(k)$ and the functor $\mathbf{Vect}(k) \longrightarrow \mathbf{Vect}(E)$ given by $X \rightsquigarrow X \otimes_k E$ give rise to homomorphisms

$$V\colon K_n(E) \longrightarrow K_n(k) \quad \text{and} \quad F\colon K_n(k) \longrightarrow K_n(E).$$

Ordinary Galois theory shows that the composite functor $\mathbf{Vect}(E) \longrightarrow \mathbf{Vect}(E)$ given by $Y \rightsquigarrow Y \otimes_k E$ can be described as the direct sum

$$\bigoplus_{g \in G} g\colon \mathbf{Vect}(E) \longrightarrow \mathbf{Vect}(E),$$

where G acts in the obvious manner. Accordingly, we have an action of G on $K_n(E)$ for which both V and F are equivariant, and a formula

$$FV = \sum_{g \in G} g.$$

Note that the equivariance of V implies that it factors through the orbits $K_n(E)_G$, and the equivariance of F implies that it factors through the fixed points $K_n(E)^G$, but these maps do not typically identify $K_n(k)$ with either the orbits or the fixed points. The data of $K_n(k)$ is an added piece of structure; that is, $K_n(k)$ cannot in general be recovered from $K_n(E)$ as a G-module.

But the problem is even deeper than this. Even if one considers all the K-groups together as a single entity (by thinking of these groups as the homotopy groups of a space or spectrum), one can construct a descent spectral sequence

$$E^2_{p,q} = H^{-p}(G, K_q(E)),$$

but this will not, as a rule, converge to the groups $K_{p+q}(k)$. In other words, the space or spectrum $K(k)$ is not the homotopy fixed point space/spectrum of the action of G on the space/spectrum $K(E)$. Consequently, even knowing the homotopy type $K(E)$ with its action of G is insufficient to recover the groups $K_n(k)$. This is the *descent problem in algebraic K-theory.*

There is, of course, no need to consider the K-theories of E and k in isolation. One can also include the information of the K-groups of all the various subextensions $E \supseteq L \supseteq k$. In other words, for any subgroup $H \leq G$, one can contemplate the K-groups $K_n(E^H)$ of the fixed field E^H. These abelian groups each have conjugation homomorphisms

$$c_g\colon K_n(E^H) \longrightarrow K_n(E^{gHg^{-1}})$$

for any $g \in G$. Additionally, for subgroups $K, L \leq H \leq G$, one again has the forgetful functor $\mathbf{Vect}(E^K) \longrightarrow \mathbf{Vect}(E^H)$ and the functor $\mathbf{Vect}(E^H) \longrightarrow \mathbf{Vect}(E^L)$ given by $Y \rightsquigarrow Y \otimes_{E^H} E^L$, so again one has homomorphisms

$$V_K^H \colon K_n(E^K) \longrightarrow K_n(E^H) \quad \text{and} \quad F_L^H \colon K_n(E^H) \longrightarrow K_n(E^L).$$

Again, a small amount of Galois theory reveals that these two homomorphisms compose in the following manner:

$$F_L^H V_K^H = \sum_{x \in L \backslash G / K} V^L_{L \cap (xKx^{-1})} c_x F^K_{(x^{-1}Lx) \cap K} \colon K_n(E^K) \longrightarrow K_n(E^L).$$

And again, of course, the groups $K_n(E^H)$ cannot be recovered from the G-module $K_n(E)$ or the homotopy type $K(E)$ with its action of G.

Combined, this structure on the assignment $H \rightsquigarrow K_n(E^H)$ makes up what is called a *Mackey functor* for G. As we see, this is strictly more structure than a G-module. Similarly, the assignment $H \rightsquigarrow K(E^H)$ is a *spectral Mackey functor* for G in the sense of the first author [2]. This is strictly more structure than a spectrum with a G-action. We call this object the *G-equivariant K-theory of E over k*.

In this monograph, we tease out the kind of structure on the categories $\mathbf{Vect}(E^H)$ that provides their K-theory with the structure of a spectral Mackey functor for G. As a first approximation, we note that, because the category of subextensions of E is equivalent to the category of transitive G-sets, the functors $Y \rightsquigarrow Y \otimes_{E^H} E^L$ together define what we call a *G-category* – a diagram of categories indexed on the opposite of the orbit category $\mathbf{O}_G$ of G. Let us write $\underline{\mathbf{Vect}}_{E \supseteq k}$ for this G-category.

Of course, the G-category $\underline{\mathbf{Vect}}_{E \supseteq k}$ is relatively simple: after all, if one thinks of the action of G on $\mathbf{Vect}(E)$, then $\mathbf{Vect}(E^H)$ is the category of E-vector spaces equipped with a semilinear action of H. In other words, $\mathbf{Vect}(E^H)$ is simply the homotopy fixed point category for the action of H on $\mathbf{Vect}(E)$. So we might at first contemplate $\mathbf{Vect}(E)$ with its G-action. However, the adjoints to the functors in this G-category – the forgetful functors – contain extra information that compels us to contemplate entire G-category structure.

For example, the forgetful functor $\mathbf{Vect}(E) \longrightarrow \mathbf{Vect}(k)$ is a kind of generalized *product* of vector spaces: we regard it as *indexed*, not over a mere set, but over the G-set G/e. To see why this is appropriate, first note that by the normal basis theorem, if Y is an E-vector space with basis $\{v_i\}_{1 \leq i \leq n}$, then there is an element $\theta \in E$ such that Y has basis $\{g\theta v_i\}_{1 \leq i \leq n, g \in G}$ over k. But without choosing this element, we would still be entitled to write

$$\prod_{\alpha \in G/e} Y$$

for this k-vector space. In the same manner, the presence of all the other right adjoints $\mathbf{Vect}(E^H) \longrightarrow \mathbf{Vect}(E^K)$ in this diagram of categories can be regarded as the existence of various *indexed products*

$$\prod_{\alpha \in K/H} Z$$

on this G-category. At the same time, since our field extensions are separable, these right adjoints are all also *left* adjoints, and so we even think of this as endowing our G-category with *indexed direct sums*

$$\bigoplus_{\alpha\in K/H} Z.$$

The point here is that the transfer structure on the equivariant algebraic K-groups arises from the additional structure of indexed products or coproducts on the G-category $\underline{\mathbf{Vect}}_{E\supseteq k}$. And this example refects a general principle: to get the full structure of a Mackey functor on equivariant algebraic K-theory of E over k, one must work not only with the diagram of categories indexed by $\mathbf{O}_G^{op}$, but also the G-direct sums thereupon.

The G-category $\underline{\mathbf{Vect}}_{E\supseteq k}$ also carries a sophisticated multiplicative structure. Of course, the tensor product over k provides an *external product*

$$\mathbf{Vect}(E^K)\times\mathbf{Vect}(E^L)\longrightarrow\mathbf{Proj}^{fg}(E^K\otimes_k E^L)\simeq\prod_{x\in L\backslash G/K}\mathbf{Vect}(E^{(x^{-1}Lx)\cap K}).$$

In [9], we demonstrated that the external products provide the equivariant algebraic K-groups with the structure of a graded Green functor, and, even better, they provide the equivariant algebraic K-theory spectra with the structure of a spectral Green functor.

However, there is a still richer multiplicative structure, whose impact on equivariant K-theory is studied here for the first time. Just as the usual norm of an element of E is automatically Galois-invariant, we see that for any finite-dimensional E-vector space V, the tensor power $V^{\otimes G}$ comes with canonical descent data. We call the resulting k-vector space $N_E^k(V)$ the *multiplicative norm* from E to k. Quite simply, $N_E^k(V)$ is the k-vector space (of dimension $(\dim V)^{\#G}$) such that the set $\mathrm{Hom}_k(N_E^k(V),W)$ is in bijection with the set of *norm forms* $V^{\times G}\longrightarrow W\otimes_k E$ *for* E/k – i.e., k-multilinear maps

$$\Phi\colon V^{\times G}\longrightarrow W\otimes_k E$$

such that for any element $(v_h)_{h\in G}\in V^{\times G}$, any element $g\in G$, and any element $\lambda\in E$,

$$\Phi((v'_h)_{h\in G})=(g\lambda)\Phi((v_h)_{h\in G}),$$

where

$$v'_h=\begin{cases}\lambda v_g & \text{if } h=g;\\ v_h & \text{if } h\neq g,\end{cases}$$

and

$$g\Phi((v_h)_{h\in G})=\Phi((v_{gh})_{h\in G}.$$

So, $N_E^k(V)$ is the dual of the k-vector space of norm forms $V^{\times G}\longrightarrow E$ for E/k. In particular, when $k=\mathbf{R}$ and $E=\mathbf{C}$, then $N_{\mathbf{C}}^{\mathbf{R}}(V)$ is precisely the dual space of the $\mathbf{R}$-vector space of hermitian forms on V.

More generally, there are multiplicative norms for any subgroups $K\leq L\leq G$. Together with the external products, these multiplicative norms furnish $\underline{\mathbf{Vect}}_{E\supseteq k}$ with a *G-symmetric monoidal structure*. In effect, this provides tensor products indexed over any finite G-set $U=\coprod_{i\in I}(G/H_i)$, which amount to functors

$$\bigotimes_{u\in U}\colon\prod_{i\in I}\mathbf{Vect}(E^{H_i})\longrightarrow\mathbf{Vect}(k),$$

which are suitably associative and commutative.

This additional structure on $\underline{\mathbf{Vect}}_{E\supseteq k}$ descends to an analogous structure on the equivariant algebraic K-theory of E over k. These provide the equivariant algebraic K-theory of E over k with the full structure of a *G-E_∞-algebra*.

Hill's program

To tell this story, we pursue here the general theory of *G-∞-categories*. But we are by no means the first to contemplate this possibility.

In their landmark solution of the Kervaire Invariant Problem [23], Mike Hill, Mike Hopkins, and Doug Ravenel developed a perspective on equivariant stable homotopy thery that centered on the study of indexed products, indexed coproducts, and indexed symmetric monoidal structures (incorporating their multiplicative norms). They argued that these structures were fundamental to the basic structure of equivariant stable homotopy theory.

In 2012, Hill presented (partly jointly with Hopkins) a sketch of a program to rewire huge swaths of higher category theory in order to embed these structures into the very fabric of the homotopy theory of homotopy theories. Hill sought a theory of G-∞-categories and G-functors, along with a concomitant theory of internal homs, G-limits, G-colimits, G-Kan extensions, etc. He furthermore conjectured that, equipped with this technology, one could prove the following, which is an analogue of the universal property of the ∞-category **Top** of spaces.

Theorem A. *The G-∞-category $\underline{\mathbf{Top}}_G$ of G-spaces – whose value on an orbit G/H is the ∞-category of H-spaces – is freely generated under G-colimits by the contractible G-space; that is, for any G-∞-category D with all G-colimits, evaluation on the generator defines an equivalence of G-∞-categories*

$$\underline{\mathrm{Fun}}_G^L\left(\underline{\mathbf{Top}}_G, D\right) \xrightarrow{\sim} D.$$

Here $\underline{\mathrm{Fun}}_G^L$ is the G-∞-category of G-colimit-preserving functors.

In this text, we develop all this machinery, and this is the first main theorem.

Recall that one may speak of semiadditive ∞-categories, in which finite products and finite coproducts exist and coincide. In the same manner, Hill expected that one may speak of G-semiadditive ∞-categories, in which finite G-products and finite G-coproducts exist and coincide. Furthermore, the effective Burnside ∞-category $A^{\mathit{eff}}(\mathbf{F})$ of finite sets is equivalent to the ∞-category of finitely generated free E_∞-spaces, whence it is the free semiadditive ∞-category on one generator. Accordingly, in equivariant higher category theory, we have the following.

Theorem B. *The G-∞-category $\underline{A}^{\mathit{eff}}(G)$ – whose value on G/H is the effective Burnside ∞-category of finite H-sets – is equivalent to the G-∞-category of finitely generated free G-E_∞-spaces. In other words, it is the free G-semiadditive G-∞-category on one generator; that is, for any G-semiadditive G-∞-category A, evaluation on the generator defines an equivalence of G-∞-categories*

$$\underline{\mathrm{Fun}}_G^{\oplus}\left(\underline{A}^{\mathit{eff}}(G), A\right) \xrightarrow{\sim} A.$$

Here $\underline{\mathrm{Fun}}_G^{\oplus}$ is the G-∞-category of G-coproduct-preserving functors.

As suggested by work of Andrew Blumberg [14], the G-stability of a G-∞-category can be defined as ordinary stability along with G-semiadditivity. Consequently, the two previous theorems, with some effort, together provide the following, also conjectured by Hill:

Theorem C. *The G-∞-category $\underline{\mathbf{Sp}}^G$ of G-spectra – whose value on an orbit G/H is the ∞-category $\mathbf{Sp}^H$ of genuine H-spectra – is the free G-stable G-∞-category with all G-colimit on one generator; that is, for any G-stable G-∞-category E, evaluation on the generator defines an equivalence of G-∞-categories*

$$\underline{\mathrm{Fun}}_G^L\left(\underline{\mathbf{Sp}}^G, A\right) \xrightarrow{\sim} A.$$

Going further, Hill also expected that the multiplicative norms of Hill–Hopkins–Ravenel would be part of a new type of structure – a *G-symmetric monoidal G-∞-category.* In effect, a G-symmetric monoidal G-∞-category is a G-∞-category C along with tensor product functors over finite G-sets. In particular, one has a functor

$$N^G\colon C(G/e) \longrightarrow C(G/G),$$

which is exactly the desired multiplicative norm.

Work of Hill and Hopkins [22] has already laid out the idea of G-symmetric monoidal ordinary categories, but incorporating homotopy coherence into this sort of structure is a taller order. The situation is roughly analogous to the situation with the smash product in model categories of spectra: there are genuine obstructions to making a G-symmetric monoidal structure maximally compatible with a model category of genuine G-spectra. However, when we pass to the world of ∞-categories as in [24], the situation becomes much cleaner: not only can one give an explicit, homotopy invariant construction of the smash product on the ∞-category $\mathbf{Sp}$ of spectra, but this smash product enjoys a universal property that characterizes it up to a contractible space of choices.

We bring exactly this kind of conceptual clarity (and technical power) to the study of homotopy coherent G-commutative structures in this text. We define the notions of *G-∞-operad* and *G-symmetric monoidal G-∞-category.* We find that G-products define G-symmetric monoidal structures on the G-∞-category $\underline{\mathbf{Cat}}_{\infty,G}$ of G-∞-categories and the G-∞-category $\underline{\mathbf{Top}}_G$ of G-spaces. The G-commutative algebra objects of $\underline{\mathbf{Cat}}_{\infty,G}$ are precisely the G-symmetric monoidal ∞-categories, and the G-commutative algebra objects of $\underline{\mathbf{Cat}}_{\infty,G}$ are precisely the G-E_∞-spaces.

Similarly, there is a G-subcategory $\underline{\mathbf{Pr}}_G^L \subset \underline{\mathbf{Cat}}_{\infty,G}$ of G-presentable G-∞-categories and G-left adjoints. This too has a G-symmetric monoidal structure, but it is not given by G-products; rather, the G-commutative algebra objects of $\underline{\mathbf{Pr}}_G^L$ are precisely the G-symmetric monoidal ∞-categories that are presentable and in which the tensor product preserves G-colimits separately in each variable.

Theorem D. *The G-∞-category $\underline{\mathbf{Top}}_G$ is the unit in the G-symmetric monoidal G-∞-category $\underline{\mathbf{Pr}}_G^L$. In particular, it admits an essentially unique G-symmetric monoidal structure in which the tensor product preserves G-colimits separately in each variable, which is given by the G-products.*

Even further, the full G-subcategory $\underline{\mathbf{Pr}}_{G,st}^L \subset \underline{\mathbf{Pr}}_G^L$ spanned by the G-stable G-presentable G-∞-categories inherits the G-symmetric monoidal structure, and we have the following.

Theorem E. *The G-∞-category $\underline{\mathbf{Sp}}^G$ is the unit object in the G-symmetric monoidal G-∞-category $\underline{\mathbf{Pr}}^L_{G,st}$. In particular, it admits an essentially unique G-symmetric monoidal structure in which the tensor product preserves G-colimits separately in each variable.*

In particular, this provides a universal description of the Hill–Hopkins–Ravenel multiplicative norm. With some work, this even provides a universal characterization of an *individual* norm functor.

Theorem F. *The norm functor $N^G\colon \mathbf{Sp} \longrightarrow \mathbf{Sp}^G$ is the inital object of the ∞-category*

$$\mathrm{Fun}^{\otimes}(\mathbf{Sp}, \mathbf{Sp}^G) \times_{\mathrm{Fun}^{\otimes}(\mathbf{Top}, \mathbf{Sp}^G)} \mathrm{Fun}^{\otimes}(\mathbf{Top}, \mathbf{Sp}^G)_{\Sigma^{G,\infty}_{+} \circ \Pi_G /},$$

where $\Pi_G\colon \mathbf{Top} \longrightarrow \mathbf{Top}^G$ is the G-product, and $\mathrm{Fun}^{\otimes}$ denotes the ∞-category of symmetric monoidal functors.

In this text, we completely realize Hill's vision, and we prove Theorems A–F.

Taking the G out of Genuine

Formally, one may now note that the orbit category $\mathbf{O}_G$ of the group G plays a much more significant role in these results than does G itself. In particular, although the ∞-category $\mathbf{Sp}^G$ can be obtained by taking the ∞-category $\mathbf{Top}_G$ and inverting the representation spheres, our viewpoint regards the role of representation spheres as incidental.

One is thus led to ask whether one might untether equivariant homotopy theory from dependence upon a group. (We thank Haynes Miller for the pun of the section heading.) That is, first, do Theorems A–F hold more generally? And, second, is there any value in proving them in greater generality? The answer to both questions turns out to be *yes*.

Indeed, when one examines the proofs of the results above, one finds that the unstable results continue to hold when $\mathbf{O}_G$ is replaced with any base ∞-category T. The stable results require only very mild conditions on T; in effect, one requires the analogue of the Mackey decomposition theorem in T ("T is *orbital*") and a condition that no nontrivial retracts exist ("T is *atomic*"). We can even extend this further, and define an *incompleteness class* R on the orbital ∞-category T; in effect, this serves to place limits on the classes of transfers that exist in the corresponding ∞-category of spectra.

As it happens, there are many examples that make this generality worthwhile. Here are a few.

1. As a mild extension of the example $\mathbf{O}_G$, consider a family $\mathscr{F}$ of subgroups of G such that if $K \leq L$ lie in $\mathscr{F}$, then any subgroup $H \leq G$ that is conjugate to a subgroup H' such that $K \leq H' \leq L$ also lies in $\mathscr{F}$. Then the full subcategory $\mathbf{O}_{G,\mathscr{F}} \subseteq \mathbf{O}_G$ is also an atomic orbital category. Such categories (along with various inclusions of "closed" and "open" subcategories) appear naturally when we contemplate the isotropy separation sequence in equivariant stable homotopy theory.
2. Following Blumberg and Hill [15], any incomplete G-universe U gives rise to an incompleteness class R_U on $\mathbf{O}_G$, and this permits us to model G-spectra relative to U.

3. Furthermore, one can also work with orbit categories of profinite groups (where the stabilizers are required to be open) and locally finite groups (where the stabilizers are required to be finite). This provides extensions of equivariant stable and unstable homotopy theory to these contexts.
4. Any ∞-groupoid (= Kan complex) X is atomic orbital. The corresponding ∞-category of X*-spaces* is equivalent to the ∞-category of functors $X \longrightarrow \mathbf{Top}$; likewise, the ∞-category of X*-spectra* is equivalent to the ∞-category of functors $X \longrightarrow \mathbf{Sp}$. In other words, X-spaces are local systems of spaces over X, and X-spectra are local systems of spectra over X. Consequently, this example actually recovers parametrized homotopy theory as studied by Peter May and Johann Sigurdsson [25]; in fact, this example was the inspiration for our title.
5. Combining the previous example with the ur-example, for any G-space X, one can construct the *total orbital* ∞*-category* $\underline{\mathrm{X}}$. One sees that $\underline{X}$-spaces are local systems of G-spaces over X, and $\underline{X}$-spectra are local systems of G-spectra over X.
6. The cyclonic orbit 2-category $\mathbf{O}_{©}$, whose objects are $\mathbf{Q}/\mathbf{Z}$-sets with finite stabilizers, whose 1-morphisms are equivariant maps, and whose 2-morphisms are certain intertwiners, is an orbital ∞-category [8]. The corresponding homotopy theory of B-spectra is the homotopy theory of S^1-equivariant spectra relative to the family of finite subgroups. This is precisely the sort of equivariance that one sees on topological Hochschild homology [6]. To construct the homotopy category of *cyclotomic* spectra, one forms the fixed points of this homotopy theory relative to the action of the monoid of *open immersions* from $\mathbf{O}_{©}$ into itself.
7. Generalizing the previous example are the *multi-cyclonic orbit* 2*-categories* which control torus-equivariance and *multi-cyclotomic* structures, which appear naturally on higher forms of topological Hochschild homology [5].
8. The 2-category Γ of finite connected groupoids and covering maps is atomic orbital. The corresponding homotopy theory of Γ-spectra is a variant of Stefan Schwede's global equivariant homotopy theory [27]. To get *exactly* Schwede's global equivariant homotopy theory (for finite groups) in our framework requires a larger orbital ∞-category of finite connected groupoids equipped with an incompletness class.
9. The category $\mathbf{Surj}_{\leq n}$ of finite sets of cardinality $\leq n$ and surjective maps is an atomic orbital category. This one is extremely strange, however, as it doesn't have much at all to do with any groups. Nevertheless, the third author shows in [21] that the corresponding homotopy theory of $\mathbf{F}_{\leq n}$-spectra is equivalent to the homotopy theory of n-excisive functors $\mathbf{Sp} \longrightarrow \mathbf{Sp}$, generalizing Tom Goodwillie's classification of homogeneous functors. Indeed, it is the inclusion of $\mathbf{Surj}_{\leq n-1}$ into $\mathbf{Surj}_{\leq n}$, combined with the complmentary inclusion of $B\Sigma_n$ into $\mathbf{Surj}_{\leq n}$, that together reconstruct the recollement of n-excisive functors by $(n-1)$-excisive functors and n-homogeneous functors.
10. The ∞-categories $\mathbf{Surj}(\mathbf{R})_{\leq n}$ and $\mathbf{Surj}(\mathbf{C})_{\leq n}$ obtained from the topological categories of finite-dimensional inner product spaces (over $\mathbf{R}$ and $\mathbf{C}$, respectively) of dimension $\leq n$ and orthogonal projections are atomic orbital as well. Just as stable homotopy theory parametrized on the orbital categories $\mathbf{Surj}_{\leq n}$ "controls" the Goodwillie tower, so the stable homotopy theory parametrized on the

orbital categories $\mathbf{Surj}(\mathbf{R})_{\leq n}$ "controls" the Weiss orthogonal calculus [29]. Likewise, stable homotopy theory parametrized on the orbital categories $\mathbf{Surj}(\mathbf{C})_{\leq n}$ "controls" the unitary calculus. We hope to return to this point in future work.

11. Our framework also covers and extends a setting previously defined in work of Bill Dwyer and Dan Kan, Emanuel Dror Farjoun, and Boris Chorny and Bill Dwyer. In [19], Farjoun builds on work of [20] and defines a model structure on the category of diagrams of spaces indexed on a small category I, called the I-equivariant model structure, which depends on the "I-orbits": the diagrams $I \longrightarrow \mathbf{Top}$ whose strict (= 1-categorical) colimit is equal to a point. In particular if $I = G$ is a group these are precisely the G-orbits, and the resulting homotopy theory is the fixed-points model structure on G-spaces. Moreover Farjoun's construction admits an Elmendorf–McClure theorem, in the sense that the I-equivariant model structure is Quillen-equivalent to a presheaf category (on the orbit category when the orbits are either small or complete). This result was proved in different levels of generality in [20] and [17], and in full generality in the more recent [16]. The category of I-orbits $\mathbf{O}_I$ is an atomic orbital category, and by the above mentioned Elmendorf–McClure theorem, Farjoun's I-equivariant model category is equivalent to our homotopy theory of $\mathbf{O}_I$-spaces. Our construction exhibits the I-equivariant homotopy theory as a fiber of a full-fledged $\mathbf{O}_I$-category, thus enabling one to exploit the full theory of $\mathbf{O}_I$-equivariant limits and colimits.

Such a wealth of examples compels us to prove Theorems A–F in the generality atomic orbital ∞-categories, and, where possible, we develop elements of the theory in even greater generality.

Plan

This text consists of nine Exposés:

I. We introduce the basic elements of the theory of *parametrized ∞-categories* and functors between them. Following the lessons of [13], these notions are defined as suitable fibrations of ∞-categories and functors between them. We give as many examples as we are able at this stage. Simple operations, such as the formation of opposites and the formation of functor ∞-categories, become slightly more involved in the parametrized setting, but we explain precisely how to perform these constructions. All of these constructions can be performed explicitly, without resorting to such acts of desperation as straightening. The key results of this Exposé are: (1) a universal characterization of the T-∞-category of T-objects in any ∞-category, (2) the existence of an internal Hom for T-∞-categories, and (3) a parametrized Yoneda lemma. [3]

II. We dive deep into the fundamentals of parametrized ∞-category theory in the second Exposé. In particular, we construct parametrized versions of join and slice, and use these to define *parametrized colimits and limits* as well as *parametrized left and right Kan extensions*. At the heart of this is the difficult but technically powerful result that, just as one may decompose colimits into coproducts and geometric realizations in ∞-category theory, similarly one may decompose parametrized colimits into parametrized coproducts and geometric realizations in the ordinary sense. This has the effect of elevating parametrized coproducts and products to a special status within the theory. Theorem A is proved (and generalized) here. [28]

III. We next introduce *orbital ∞-categories*, along with a host of examples. There are actually different sorts of functor between orbital ∞-categories, and we taxonomize these according to certain algebro-geometric intuitions. For any orbital ∞-category T, we have a corresponding ∞-category $\mathbf{Sp}^T$ (even T-∞-category) of *T-spectra*, which under our algebro-geometric analogy corresponds roughly to an ∞-category of "quasicoherent sheaves on T." The different sorts of functors between orbital ∞-categories induce suitable functors between the ∞-categories of T-spectra, and these behave as the names suggest. Perhaps most importantly, *closed immersions* of orbital ∞-categories admit *open complements*, and these two functors induce a *recollement* of the corresponding ∞-category of spectra; this is how one obtains the *isotropy separation sequence* and generalizations thereof. With a little care, we are able to extend all this to the context of an orbital ∞-category equipped with an incompleteness class. [7]

IV. In the fourth Exposé, we define *semiadditive parametrized ∞-categories*, and we prove Theorem B. Then we use the work of Exposé II to show that parametrized stability can be expressed as ordinary stability combined with parametrized semiadditivity. This now makes it possible to prove Theorem C. [26]

V. Next, we introduce the notion of *parametrized Waldhausen ∞-categories*. We show that the algebraic K-theory of a Waldhausen T-∞-category naturally carries the structure of a T-spectrum. [1]

VI. From here, we move toward the algebraic structures in parametrized higher category theory. We introduce the notions of *T-∞-operad* and *T-symmetric monoidal ∞-category* for an orbital ∞-category T, and we offer up numerous examples. Perhaps most importantly, parametrized ∞-categories with all T-coproducts (or, dually, T-products) inherit canonical T-symmetric monoidal structures. [4]

VII. In the seventh Exposé, we prove that when T is an atomic orbital ∞-category, the T-∞-category $\underline{\mathbf{Pr}}_T^L$ of T-presentable T-∞-categories admits a T-symmetric monoidal structure analogous to the symmetric monoidal structure on presentable ∞-categories. Theorem A then implies, more or less directly, Theorem D. Moreover, T-stable T-presentable T-∞-categories form a symmetric monoidal localization of $\underline{\mathbf{Pr}}_T^L$, and the localization is given by tensoring with $\underline{\mathbf{Sp}}^T$. Theorem E follows immediately. Moreover, one deduces a different universal property of $\underline{\mathbf{Sp}}^T$, which is that it is, in effect, the result of inverting the analogues of the permutation representation spheres in the T-symmetric monoidal T-∞-category $\underline{\mathbf{Top}}_G$. From this, we are able to deduce the universal property of the norm (Theorem F). [12]

VIII. In the penultimate Exposé, we introduce the T-∞-category $\underline{\mathbf{Mod}}(A)$ of modules over a T-E_∞-algebra A (for an atomic orbital ∞-category T). We show that it is T-symmetric monoidal, and we describe how it transforms in both A and T. [11]

IX. Finally, we return to the subject of equivariant algebraic K-theory, where we show that the equivariant algebraic K-theory of a T-symmetric monoidal Waldhausen T-∞-category admits the natural structure of a T-E_∞ ring spectrum. This applies not only in the field case of the beginning of this introduction, but also to those forms of equivariant algebraic K-theory that arise in the work of Dustin Clausen, Akhil Mathew, Niko Naumann, and Justin Noel [18] as well as the nascent subject of equivariant (derived) algebraic geometry. [10]

Acknowledgments

This text answers a web of questions and conjectures posed by Mike Hill and Mike Hopkins. We thank them for presenting us with these questions in the afterglow of their solution with Doug Ravenel to the Kervaire Invariant Problem, as well as for their encouragement as we developed this project. We thank Mike Hill in particular for his vision in presenting his extensive program to build up the foundations of equivariant derived algebraic geometry.

Additionally, we thank the other participants of the Bourbon Seminar at MIT – Lukas Brantner, Peter Haine, Marc Hoyois, and Akhil Mathew, for the many, many conversations we had with them over the course of the completion of this text. We also thank John Berman for his very surprising insights.

Stratified categories, geometric fixed points and a generalized Arone-Ching theorem

Saul Glasman

November 22, 2017

Abstract

We develop a theory of Mackey functors on epiorbital categories which simultaneously generalizes the theory of genuine G-spectra for a finite group G and the theory of n-excisive functors on the category of spectra. Using a new theory of stratifications of a stable ∞-category along a finite poset, we prove a simultaneous generalization of two reconstruction theorems: one by Abram and Kriz on recovering G-spectra from structure on their geometric fixed point spectra for abelian G, and one by Arone and Ching that recovers an n-excisive functor from structure on its derivatives. We deduce a strong splitting theorem for $K(n)$-local G-spectra and reprove a theorem of Kuhn on the $K(n)$-local splitting of Taylor towers.

1 Introduction

Equivariant stable homotopy theory has become notorious for its profusion of fixed point functors. The most superficially arcane of these, the *geometric fixed points* first defined in [LMS86, §II.9], also have the best formal properties. Let G be a finite group and H a subgroup; let $\mathbf{Sp}^G$ be the ∞-category of genuine G-spectra. Then the geometric H-fixed point spectrum, which we will regard as a functor

$$\Phi^H : \mathbf{Sp}^G \to \mathbf{Sp},$$

is uniquely determined by the following properties:

1. Φ^H commutes with all homotopy colimits, and
2. Φ^H is compatible with the suspension spectrum functor in that the diagram of functors

$$\begin{array}{ccc} \mathbf{Top}^G & \xrightarrow{\Sigma^\infty_+} & \mathbf{Sp}^G \\ \downarrow{\scriptstyle (-)^H} & & \downarrow{\scriptstyle \Phi^H} \\ \mathbf{Top} & \xrightarrow{\Sigma^\infty_+} & \mathbf{Sp} \end{array}$$

commutes.

The following additional pleasant properties follow:

3. Φ^H has a natural enhancement to a symmetric monoidal functor.

4. (Geometric fixed point Whitehead theorem) If E is a G-spectrum such that $\Phi^H E$ is contractible for *all* subgroups H of G, then E itself is contractible.

This last property strongly suggests that it might be possible to present G-spectra as diagrams of their geometric fixed point spectra, much as the spectral Mackey functor approach of [GM11] and [Bar14] employs the genuine fixed point spectra E^H. Such a presentation would obviously be desirable, since there are many spectra - for example, those arising as norms in the sense of [HHR09, §B.5] - whose geometric fixed points are much more accessible than their genuine fixed points. Some subtlety turns out to be required in this. For example, already for $G = C_2$, it's easy to see that the spaces of natural transformations in both directions between Φ^G and the underlying spectrum, or identity fixed point, functor $\Phi^{\{e\}}$ are contractible. Nevertheless, it can be done, and in this paper, we give a construction that accomplishes this and significantly more, drawing together work of Abram and Kriz [AK13] and Arone and Ching [AC15], which itself generalizes previous work of Bauer and McCarthy [BM03]. We stress that this presentation gives a completely new model of G-spectra in which the fundamental data are geometric fixed point spectra, their homotopical actions by groups derived from G, and gluing data relating these. To motivate this generalization, we'll draw attention to an analogy between equivariant stable homotopy theory and functor calculus, which was first pointed out to us by Mike Hopkins. For $G = C_2$ and a G-spectrum E, we have a natural cofiber sequence, the *norm cofibration sequence*

$$E_{hG} \to E^G \to \Phi^G E.$$

On the other hand, suppose that $F : \mathbf{Sp} \to \mathbf{Sp}$ is a reduced 2-excisive functor in the sense of Goodwillie [Goo91]. Then the Taylor tower of F is simply a cofiber sequence of functors

$$D_2 F \to F \to P_1 F$$

where $D_2 F$ is the 2-homogeneous part of F and $P_1 F$ is the 1-excisive approximation. Fixing a spectrum X, let's specialize further to the case where E is the indexed smash product $X^{\wedge C_2}$ and F is the functor

$$W : \mathbf{Sp} \to \mathbf{Sp}, \quad W(T) = (T^{\wedge C_2})^{C_2},$$

evaluated on X. Then the norm cofibration sequence and the Taylor tower become equivalent cofiber sequences

$$(X^{\wedge C_2})_{hC_2} \to (X^{\wedge C_2})^{C_2} \to X.$$

This equivalence can be made into the basis for an equivalence of ∞-categories

$$\mathbf{Sp}^{C_2} \simeq \mathrm{Fun}^{\text{2-exc}}(\mathbf{Sp}, \mathbf{Sp})$$

between $\mathbf{Sp}^{C_2}$ and the category of reduced 2-excisive functors $\mathbf{Sp} \to \mathbf{Sp}$ under which the identity fixed points correspond to the second derivative and the geometric C_2-fixed points correspond to the first derivative.

This coincidence suggests the existence of a systematic analogy between Goodwillie derivatives and geometric fixed points. This paper develops a common context for the Goodwillie calculus of functors between stable ∞-categories and equivariant stable homotopy theory - that of *Mackey functors on epiorbital categories* - which makes this analogy precise. In brief, n-excisive functors are governed by the category $\mathcal{F}_s^{\leq n}$ of finite sets of cardinality at most n and surjective maps in precisely the same way as G-spectra are governed by the category $\mathcal{O}_G$ of transitive G-sets, and the visible equivalence of categories between $\mathcal{F}_s^{\leq 2}$ and $\mathcal{O}_{C_2}$ accounts for the equivalence between $\mathbf{Sp}^{C_2}$ and $\mathrm{Fun}^{\text{2-exc}}(\mathbf{Sp}, \mathbf{Sp})$.

A beautiful presentation of n-excisive functors on spectra via structure on their derivatives has been constructed by Arone and Ching in [AC15], and we extend their result to our more general context, where it provides the desired presentation of the ∞-category of G-spectra. Along the way, we develop a formalism of *stratified stable ∞-categories* that encompasses, on the one hand, the category of Mackey functors on a epiorbital category, and on the other hand, monoidal stable ∞-categories equipped with a family of homological localizations, such as the category of p-local spectra with its chromatic filtration. Our theorem will be a special case of a general reconstruction theorem for objects of stratified stable ∞-categories. In the context of families of homological localizations, similar results have been obtained by Antolín-Camarena and Barthel [ACB14]. In upcoming work, we plan to use this presentation to give an explicit and homotopy-invariant description of the Hill-Hopkins-Ravenel norm.

The structure of the paper is as follows. In Section 2, we develop the theory of epiorbital categories and their Mackey functors, culminating in the statement and proof of our version, Theorem 2.38, of the Arone-Ching comonadicity theorem [AC15, Theorem 3.13]. In Section 3, we define stratified stable ∞-categories (Definition 3.5) and give several examples, then state and prove the classification of objects of a stratified stable ∞-category (Theorem 3.21), in effect giving a description of the category of coalgebras for the comonad of Section 2. We unpack the implications of our theorem for C_p-spectra in detail in Examples 3.29, obtaining the classical description of C_p-spectra via the Tate fracture square. Finally, in the short Section 4, we prove a strong and general splitting theorem reminiscent of the tom Dieck splitting, Theorem 4.2, for Mackey functors valued in $K(n)$-local spectra, recovering a result of Kuhn [Kuh04] on functor calculus. We believe the G-spectrum case of this theorem to be new.

This project has benefited from conversations with Greg Arone, Clark Barwick, Michael Ching, Jacob Lurie, Randy McCarthy and Tomer Schlank. A significant part of the impetus for the paper came from a question posed by Mike Hopkins to Clark Barwick. We thank Clark Barwick for emphasizing the importance of the nonabelian derived category and describing how to deduce Theorem 2.32 from Lemma 2.36. We thank David Ayala, Aaron Mazel-Gee and Nick Rozenblyum for pointing out an erroneous hypothesis in Definition 3.5. Finally, we wish to thank all of the participants of the Bourbon Seminar for

generating and sustaining an environment of such productivity week after week.

2 Epiorbital categories and Mackey functors

Our Arone-Ching theorem will be applicable to a certain class of "generalized equivariant homotopy theories" that encompasses the usual theory of genuine G-spectra and the theory of n-excisive functors on spectra. Such a theory springs from a "epiorbital category" with properties similar to the category of orbits for a finite group G.

Definition 2.1. A *epiorbital category* or EOC is an essentially finite category $\mathcal{M}$ satisfying the following condtions:

- Every morphism in $\mathcal{M}$ is an epimorphism.
- $\mathcal{M}$ admits pushouts and coequalizers; equivalently, $\mathcal{M}$ admits colimits over finite connected diagrams.

Epiorbital categories have a strong directionality.

Definition 2.2. It follows immediately from Yoneda's lemma that any endomorphism in a epiorbital category is an isomorphism, and so the set of isomorphism classes of objects of $\mathcal{M}$ carries a natural partial order wherein $[X] \geq [Y]$ if and only if the morphism set $\mathcal{M}(X, Y)$ is nonempty. We'll call this poset $\mathcal{P}_{\mathcal{M}}$.

Example 2.3. Let G be a finite group. Then the *orbit category* $\mathcal{O}_G$, which is defined as the category of sets with transitive G-action, is a EOC.

Example 2.4. If G is a finite group and H a subgroup, then the full subcategory

$$\mathcal{O}_{G/H} \subseteq \mathcal{O}_G$$

spanned by those orbits on which H acts trivially is again a EOC. There's no clash of notation here, for if H happens to be normal, then $\mathcal{O}_{G/H}$ is clearly just the orbit category of the group G/H.

Example 2.5. Let $\mathcal{F}_s$ be the category of finite sets and surjective maps and let $\mathcal{F}_s^{\leq n}$ be the full subcategory of $\mathcal{F}_s$ spanned by the sets of cardinality at most n. Then $\mathcal{F}_s^{\leq n}$ is a EOC.

The following properties of epiorbital categories will be useful:

Lemma 2.6. Let $\mathcal{M}$ be a EOC, let $\mathcal{K}$ be any finite category and let $\rho : \mathcal{K} \to \mathcal{M}$ be a functor. Then the overcategory $\mathcal{M}_{/\rho}$ is a EOC.

Proof. Immediate. □

Lemma 2.7. Let $\mathcal{M}$ be a EOC. Then any connected component of $\mathcal{M}$ has a final object.

Proof. We'll show that any object of $\mathcal{M}$ whose isomorphism class is minimal with respect to the natural partial order is final in its connected component. Indeed, let T be such an object and let X an object in its connected component. Then there's a zigzag of morphisms

$$T \overset{f_1}{\leftarrow} Y_1 \overset{g_1}{\rightarrow} Y_2 \overset{f_2}{\leftarrow} \cdots \overset{f_n}{\leftarrow} X.$$

By taking iterated pushouts, we can inductively replace this zigzag with a diagram

$$T \overset{f}{\rightarrow} Y \overset{g}{\leftarrow} X.$$

Moreover, by the choice of T, f must be an isomorphism, so there is a morphism from X to T. Now suppose we have a pair of morphisms

$$f, g : X \rightrightarrows T.$$

Then h, the coequalizer of f and g, is a morphism with source T, and therefore an isomorphism. By composing with h^{-1}, we see that $f = g$. □

If $\mathcal{C}$ is any category, we'll denote by $\mathcal{C}^{\amalg}$ the closure of $\mathcal{C}$ under formal finite coproducts. By definition, $\mathcal{C}^{\amalg}$ is the full subcategory of $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}et)$ spanned by the finite coproducts of representable functors. This is an operation we'll frequently want to perform on EOCs.

Example 2.8. $\mathcal{O}_G^{\amalg}$ is equivalent to $\mathcal{F}^G$, the category of all finite G-sets, since any finite G-set decomposes uniquely into orbits.

One very relevant property of $\mathcal{F}^G$ is that it's meaningful to take Mackey functors over it: $\mathcal{F}^G$ is *disjunctive* in the sense of [Bar14], so its effective Burnside ∞-category $A^{eff}(\mathcal{F}^G)$ can be formed and admits direct sums. We'll quickly recall these ideas.

Definition 2.9. Let $\mathbf{C}$ be an ∞-category which admits finite products and coproducts and a zero object. We'll say that $\mathbf{C}$ *admits direct sums*, or is *semiadditive*, if for every pair of objects $X, Y \in \mathbf{C}$, the natural map

$$X \amalg Y \to X \times Y$$

provided by the zero object is an equivalence.

Remark 2.10. It's not hard to see that each mapping space of a semiadditive ∞-category naturally carries the structure of a commutative monoid space; the term *additive* ∞-category is traditionally reserved for categories whose mapping spaces are grouplike.

Definition 2.11. An ∞-category $\mathbf{C}$ is called *disjunctive* if

- $\mathbf{C}$ admits pullbacks and finite coproducts,

- for each finite set I and for each I-tuple $(X_i)_{i\in I}$ of objects of $\mathbf{C}$, the natural functor

$$\prod_i \mathbf{C}_{/X_i} \to \mathbf{C}_{/\coprod_i X_i}$$

  is an equivalence of categories.

Let $\mathbf{C}$ be an ∞-category which admits pullbacks. Then one can construct [Bar14, 3.6] an ∞-category $A^{eff}(\mathbf{C})$, called the *effective Burnside category of* $\mathbf{C}$, whose objects are those of $\mathbf{C}$, whose morphisms are spans

$$\begin{array}{ccc} & Z & \\ \swarrow & & \searrow \\ X & & Y \end{array}$$

in $\mathbf{C}$, and where composition is performed by forming pullbacks.

Proposition 2.12. [Bar14, 4.3] If $\mathbf{C}$ is disjunctive, then $A^{eff}(\mathbf{C})$ is semiadditive.

$\square$

Example 2.13. A functor from $A^{eff}(\mathcal{F}^G)$ to $\mathbf{Ab}$ which preserves direct sums is precisely a Mackey functor in the sense of [tD73].

The content of the next lemma is that it's meaningful to talk about Mackey functors over arbitrary epiorbital categories:

Lemma 2.14. Let $\mathcal{M}$ be a epiorbital category. Then $\mathcal{M}^{\amalg}$ is disjunctive.

Proof. The condition that

$$\prod_i \mathcal{C}_{/X_i} \to \mathcal{C}_{/\coprod_i X_i}$$

is an equivalence is satisfied for any $\mathcal{C}$ of the form $\mathcal{D}^{\amalg}$, so we only need to show that $\mathcal{M}^{\amalg}$ admits pullbacks.

Let $\rho : \Lambda^2_2 \to \mathcal{M}^{\amalg}$ be a diagram

$$\begin{array}{ccc} & & X \\ & & \downarrow \\ Y & \longrightarrow & Z \end{array}$$

in $\mathcal{M}^{\amalg}$. If any of X, Y or Z are empty then the pullback exists and is empty, so let's assume all are nonempty.

If Z decomposes nontrivially as a coproduct $Z_1 \coprod Z_2$, we get a decomposition of diagrams $\rho = \rho_1 \coprod \rho_2$, and if each ρ_i admits a limit W_i, then $W_1 \coprod W_2$ is a limit of ρ. Thus it suffices to assume Z is representable.

On the other hand, if X decomposes nontrivially as $X_1 \coprod X_2$, and if

$$\begin{array}{ccc} W_1 & \longrightarrow & X_1 \\ \downarrow & & \downarrow \\ Y & \longrightarrow & Z, \end{array} \qquad \begin{array}{ccc} W_2 & \longrightarrow & X_2 \\ \downarrow & & \downarrow \\ Y & \longrightarrow & Z \end{array}$$

are pullback diagrams, then

$$\begin{array}{ccc} W_1 \coprod W_2 & \longrightarrow & X \\ \downarrow & & \downarrow \\ Y & \longrightarrow & Z \end{array}$$

is a pullback diagram. After carrying out the same argument for Y, it's enough to assume that X, Y and Z are all representable - in other words, that ρ may be lifted to a diagram $\widetilde{\rho} : \Lambda^2_2 \to \mathcal{M}$.

But it now follows from Lemma 2.6 and Lemma 2.7 that ρ admits a limit, since to give a limit of ρ in $\mathcal{M}^{\amalg}$ is, tautologically, to give a final object in each connected component of the EOC $\mathcal{M}_{/\widetilde{\rho}}$. □

Definition 2.15. There is a more general notion of *orbital ∞-category* which features centrally in the upcoming work [BDG+16]. An orbital ∞-category is simply any ∞-category $\mathcal{M}$ for which $\mathcal{M}^{\amalg}$ admits pullbacks, from which it follows that $\mathcal{M}^{\amalg}$ is disjunctive. By Lemma 2.14, epiorbital categories are orbital. Epiorbital categories are the focus of this paper, but some results will be stated for general orbital ∞-categories.

Definition 2.16. If $\mathcal{M}$ is an orbital ∞-category, we'll write $A^{eff}(\mathcal{M})$ for the effective Burnside category $A^{eff}(\mathcal{M}^{\amalg})$; we don't expect this notation to cause confusion. $A^{eff}(\mathcal{M})$ is semiadditive, and if $\mathbf{C}$ is a semiadditive presentable ∞-category, then we'll denote by $\mathbf{Mack}(\mathcal{M}, \mathbf{C})$ the category of $\mathbf{C}$-valued Mackey functors on $\mathcal{M}$: the category of additive (i.e. direct-sum-preserving) functors from $\mathcal{M}$ to $\mathbf{C}$. If $\mathbf{C} = \mathbf{Sp}$, then we'll usually omit $\mathbf{C}$ and refer to the category simply as $\mathbf{Mack}(\mathcal{M})$.

Example 2.17. When $\mathcal{M}$ is the orbit category $\mathcal{O}_G$, $\mathbf{Mack}(\mathcal{M})$ is the category of *spectral Mackey functors* for G [Bar14], which is a model for the homotopy theory of genuine G-spectra.

Example 2.18. The natural target of both the genuine fixed point functor $(-)^H$ and the geometric fixed point functor Φ^H (of which more anon) on $\mathbf{Mack}(\mathcal{O}_G)$ is $\mathbf{Mack}(\mathcal{O}_{G/H})$ (Example 2.4), even when H is not normal in G.

Theorem 2.19. When $\mathcal{M}$ is the category $\mathcal{F}_s^{\leq n}$ of Example 2.5, $\mathbf{Mack}(\mathcal{M}, \mathbf{C})$ is equivalent to the category of (reduced, filtered-colimit-preserving) n-excisive functors from $\mathbf{Sp}$ to $\mathbf{C}$. This equivalence has the property that if $F : \mathbf{Sp} \to \mathbf{C}$ is n-excisive, if E is the corresponding Mackey functor and if S is a set, then

$E(S)$ is equivalent to the S-indexed cross-effect of F evaluated on an S-indexed set of spheres. In particular, if S has n-elements, then $E(S)$ is equivalent to the nth derivative $\mathbb{D}_n F$ as spectra with Σ_n-action.

This equivalence is the subject of the separate paper [Gla16].

The following is a significant technical lemma that provides control over the values of many universally defined Mackey functors, including the fixed points of the free genuine equivariant G-spectrum on a spectrum with G-action.

Lemma 2.20. Suppose that $\mathbf{A}$, $\mathbf{B}$, $\mathbf{C}$ are semiadditive ∞-categories and $\phi : \mathbf{A} \to \mathbf{B}$, $F : \mathbf{A} \to \mathbf{C}$ are additive functors. Suppose the left Kan extension $\phi_! F : \mathbf{B} \to \mathbf{C}$ exists. Then $\phi_! F$ is additive.

Proof. We must verify that $\phi_! F$ preserves zero objects and direct sums of pairs of objects. The first is obvious, so let X, Y be objects of $\mathbf{B}$. Then

$$\phi_! F(X \oplus Y) \simeq \operatorname*{colim}_{(\phi(Z) \to X \oplus Y) \in \mathbf{A} \times_{\mathbf{B}} \mathbf{B}_{/X \oplus Y}} F(Z).$$

Let

$$a : (\mathbf{A} \times_{\mathbf{B}} \mathbf{B}_{/X}) \times (\mathbf{A} \times_{\mathbf{B}} \mathbf{B}_{/Y}) \to \mathbf{A} \times_{\mathbf{B}} \mathbf{B}_{/X \oplus Y}$$

be the functor with

$$a(\phi(Z_1) \to X, \phi(Z_2) \to Y) = (\phi(Z_1 \oplus Z_2) \simeq \phi(Z_1) \oplus \phi(Z_2) \to X \oplus Y).$$

Then we claim that a is cofinal. Thus we must verify that for each object $k : \phi(Z) \to X \oplus Y$ of $\mathbf{A} \times_{\mathbf{B}} \mathbf{B}_{/X \oplus Y}$, the overcategory

$$\mathbf{O} := (\mathbf{A} \times_{\mathbf{B}} \mathbf{B}_{/X}) \times (\mathbf{A} \times_{\mathbf{B}} \mathbf{B}_{/Y}) \times_{\mathbf{A} \times_{\mathbf{B}} \mathbf{B}_{/X \oplus Y}} (\mathbf{A} \times_{\mathbf{B}} \mathbf{B}_{/X \oplus Y})_{/k}$$

is weakly contractible. Indeed, we claim that $\mathbf{O}$ has an initial object. An object of $\mathbf{O}$ is a pair (Z_1, Z_2) of objects of $\mathbf{A}$ together with a morphism $\delta : Z \to Z_1 \oplus Z_2$ and a commutative diagram

$$\begin{array}{ccc} \phi(Z) & \xrightarrow{k} & X \oplus Y \\ \downarrow{\scriptstyle \phi(\delta)} & \nearrow & \\ \phi(Z_1 \oplus Z_2). & & \end{array}$$

Then the initial object of $\mathbf{O}$ is evidently the diagonal map $\Delta : Z \to Z \oplus Z$ together with the commutative diagram

$$\begin{array}{ccc} \phi(Z) & \xrightarrow{k} & X \oplus Y \\ \downarrow{\scriptstyle \phi(\Delta)} & \nearrow_{k_X \oplus k_Y} & \\ \phi(Z \oplus Z). & & \end{array}$$

Now there is a commutative diagram

$$\begin{array}{ccc} (\mathbf{A}\times_{\mathbf{B}}\mathbf{B}_{/X})\times(\mathbf{A}\times_{\mathbf{B}}\mathbf{B}_{/Y}) & \xrightarrow{(F\oplus F)} & \mathbf{C} \\ \downarrow a & \nearrow F & \\ \mathbf{A}\times_{\mathbf{B}}\mathbf{B}_{/X\oplus Y}, & & \end{array}$$

allowing us, by our cofinality result, to rewrite

$$\phi_! F(X\oplus Y)\simeq \underset{(\phi(Z_1)\to X,\phi(Z_2)\to Y)\in(\mathbf{A}\times_{\mathbf{B}}\mathbf{B}_{/X})\times(\mathbf{A}\times_{\mathbf{B}}\mathbf{B}_{/Y})}{\operatorname{colim}} F(Z_1)\oplus F(Z_2).$$

Now for any pair of functors $b_1, b_2 : K \to \mathbf{C}$, we have the commutation of colimits

$$\operatorname{colim}\,(b_1\oplus b_2)\simeq \operatorname{colim}\,(b_1)\oplus\operatorname{colim}\,(b_2).$$

In particular, if b_2 is the constant functor valued at some object P, then

$$\operatorname{colim}\,(b_1\oplus b_2)\simeq \operatorname{colim}\,(b_1)\oplus(P\otimes K),$$

and if K is weakly contractible, then

$$\operatorname{colim}\,(b_1\oplus b_2)\simeq \operatorname{colim}\,(b_1)\oplus P.$$

Note that $\mathbf{A}\times_{\mathbf{B}}\mathbf{B}_{/X}$ is weakly contractible for every $X\in\mathbf{B}$: indeed, the essentially unique object

$$(\mathbf{0}_A, \phi(\mathbf{0}_A)\simeq \mathbf{0}_B\to X)$$

is an initial object of $\mathbf{A}\times_{\mathbf{B}}\mathbf{B}_{/X}$. Hence

$$\begin{aligned} \phi_! F(X\oplus Y) &\simeq \underset{(\phi(Z_1)\to X,\phi(Z_2)\to Y)\in(\mathbf{A}\times_{\mathbf{B}}\mathbf{B}_{/X})\times(\mathbf{A}\times_{\mathbf{B}}\mathbf{B}_{/Y})}{\operatorname{colim}} F(Z_1)\oplus F(Z_2) \\ &\simeq \underset{(\phi(Z_1)\to X)\in\mathbf{A}\times_{\mathbf{B}}\mathbf{B}_{/X}}{\operatorname{colim}}\ \underset{(\phi(Z_2)\to Y)\in\mathbf{A}\times_{\mathbf{B}}\mathbf{B}_{/Y}}{\operatorname{colim}} F(Z_1)\oplus F(Z_2) \\ &\simeq \underset{(\phi(Z_1)\to X)\in\mathbf{A}\times_{\mathbf{B}}\mathbf{B}_{/X}}{\operatorname{colim}} F(Z_1)\oplus\phi_! F(Y) \\ &\simeq \phi_! F(X)\oplus\phi_! F(Y). \end{aligned}$$

□

If $\mathbf{I}$ and $\mathbf{J}$ are disjunctive ∞-categories and $F : \mathbf{I}\to\mathbf{J}$ is a functor which preserves pullbacks and finite coproducts, then F clearly induces an additive functor

$$A^{eff}(F) : A^{eff}(\mathbf{I})\to A^{eff}(\mathbf{J}).$$

So if $\mathbf{C}$ admits limits and colimits, we get functors

$$A^{eff}(F)_!, A^{eff}(F)_* : \mathbf{Mack}(\mathbf{I},\mathbf{C})\to\mathbf{Mack}(\mathbf{J},\mathbf{C}).$$

If $\mathcal{M}$ is an orbital ∞-category, we'll call a full subcategory $\mathcal{N}$ of $\mathcal{M}$ *downwardly-closed* if whenever $X \in \mathcal{N}$ and $Y \in \mathcal{M}$ with $\mathrm{Map}(X, Y)$ nonempty, we also have $Y \in \mathcal{N}$. Equivalently, $\mathcal{N} = \phi^{-1}(\{1\})$ for some functor $\phi : \mathcal{M} \to \Delta^1$. Upwardly-closed subcategories are defined dually.

There are plenty of examples of these: if $\mathcal{M}$ is epiorbital, then for any $X \in \mathcal{M}$, the full subcategory of $\mathcal{M}_{\leq X} \subseteq \mathcal{M}$ spanned by those objects Y with $[Y] \leq [X]$ is downwardly-closed. Note also that any downwardly-closed subcategory of an orbital ∞-category is itself orbital, and any downwardly-closed subcategory of an EOC is itself a EOC.

For the following few lemmas, we'll let $\mathcal{M}$ be orbital, let $\mathcal{N}$ be a downwardly-closed subcategory of $\mathcal{M}$ and let $\mathcal{T}$ be its upwardly-closed complement.

Lemma 2.21. The inclusion $i_{\mathcal{N}} : \mathcal{N}_{\amalg} \to \mathcal{M}_{\amalg}$ admits a canonical retraction $j_{\mathcal{N}}$ which is right adjoint to $i_{\mathcal{N}}$.

Proof. By definition, $\mathcal{M}_{\amalg}$ is the full subcategory of $\mathrm{Fun}(\mathcal{M}^{\mathrm{op}}, \mathbf{Top})$ spanned by coproducts of representables, and $i_{\mathcal{N}}$ is given by left Kan extension. But since the value of the functor represented by an object of $\mathcal{T}$ on any object of $\mathcal{N}$ is empty, the restriction $\mathrm{Fun}(\mathcal{M}^{\mathrm{op}}, \mathcal{S}et)$ to $\mathrm{Fun}(\mathcal{N}^{\mathrm{op}}, \mathcal{S}et)$ preserves coproducts of representables. This is the desired retraction. (Note that orbitality of $\mathcal{M}$ is not required for this lemma to hold.) $\square$

We should think of $j_{\mathcal{N}}$ as "formally set all objects of $\mathcal{T}$ to $\emptyset$". We note that $j_{\mathcal{N}}$ preserves coproducts.

Definition 2.22. We define the *geometric value at* $\mathcal{N}$ functor

$$\Phi^{\mathcal{N}} : \mathbf{Mack}(\mathcal{M}, \mathbf{C}) \to \mathbf{Mack}(\mathcal{N}, \mathbf{C})$$

by the left Kan extension $(A^{eff}(j_{\mathcal{N}}))_!$.

The right adjoint of $\Phi^{\mathcal{N}}$, the *extension by zero from* $\mathcal{N}$ functor, will be denoted $\Xi^{\mathcal{N}}$. For an object X of $\mathcal{M}$, we'll denote $\Phi^{\mathcal{M}_{\leq X}}$ by Φ^X. If E is an object of $\mathbf{Mack}(\mathcal{M}, \mathbf{C})$, then we'll write $E^{\Phi X}$ for the value of $\Phi^X E$ on X, the "geometric fixed point spectrum at X".

Example 2.23. Let G be a finite group and let $H \leq G$ be a subgroup. If $\mathcal{M} = \mathcal{O}_G$, then $\Phi^{G/H}$ is the classical functor of geometric fixed points [Bar14, Example B.6]. Here the usual notation would be Φ^H, not $\Phi^{G/H}$, and we apologize for the clash.

We have an equivalence

$$(\mathcal{O}_G)_{\leq G/H} \simeq \mathcal{O}_{G/H}$$

and so $\Phi^{G/H}$ naturally takes values in $\mathbf{Mack}(\mathcal{O}_{G/H})$, as previously claimed.

Example 2.24. If $\mathcal{M} = \mathcal{F}_s^{\leq n}$, and $k < n$, then $\Xi^{\mathcal{F}_s^{\leq k}}$ is the functor which regards a k-excisive functor as an n-excisive functor, and its left adjoint $\Phi^{\mathcal{F}_s^{\leq k}}$ is the k-excisive approximation functor.

Definition 2.25. Using the notation of Lemma 2.21, let $A^{eff}(\mathcal{T})$ be the effective Burnside category of $(\mathcal{T})^{\amalg}$, or equivalently, the full subcategory of $A^{eff}(\mathcal{M})$ spanned by the objects of $(\mathcal{T})^{\amalg}$. Let $A^{eff}(i_{\mathcal{T}})$ be the inclusion of this full subcategory.

Remark 2.26. Let $\mathcal{G}$ be a groupoid. We can form the effective Burnside category $A^{eff}(\mathcal{G})$, since any commutative square in a groupoid is a pullback square. Moreover, there's a natural equivalence of ∞-categories

$$c_{\mathcal{G}} : A^{eff}(\mathcal{G}) \xrightarrow{\sim} \mathcal{G}$$

which maps the span

$$x \xleftarrow{g} y \xrightarrow{h} z$$

to the morphism $hg^{-1} : x \to z$. We'll sometimes implicitly invoke this equivalence.

If X is an object of $\mathcal{M}$, let $\mathcal{G}_X$ be the groupoid spanned by the isomorphism class of X. Form the effective Burnside category $A^{eff}(\mathcal{G}_X^{\amalg})$ and let $i_X : A^{eff}(\mathcal{G}_X) \to A^{eff}(\mathcal{M}_{\leq X})$ be the inclusion. It follows from the directionality of $\mathcal{M}_{\leq X}$ that i_X is fully faithful.

Since there's no room for meaningful transfer maps, we might guess that a Mackey functor on a group $\mathcal{G}$ contains no more information than an object with $\mathcal{G}$-action. This is indeed the case, but the proof is technical and so we defer the bulk of it to Appendix A.

Theorem 2.27. Let $\mathcal{G}$ be a groupoid. Then $A^{eff}(\mathcal{G}^{\amalg})$ is the free semiadditive ∞-category on $\mathcal{G}$: for any semiadditive ∞-category $\mathbf{C}$, the natural inclusion induces an equivalence of categories

$$\mathrm{Fun}^{\oplus}(A^{eff}(\mathcal{G}^{\amalg}), \mathbf{C}) \to \mathrm{Fun}(\mathcal{G}, \mathbf{C}).$$

We'll use this equivalence implicitly from now on.

The class of Mackey functors left or right Kan extended from groupoids is an interesting one. For instance, let G be a finite group and let X be a spectrum with G-action, which by Theorem 2.27 we may regard as an object of $\mathbf{Mack}(\mathcal{G}_{G/e})$. Denote by $i : \mathcal{G}_{G/e}^{\amalg} \hookrightarrow \mathcal{F}_G$ the inclusion. Then the left Kan extension of X along $A^{eff}(i)$ is the *free genuine G-spectrum on X*, often denoted by

$$EG_+ \wedge X.$$

Similarly, the right Kan extension is the *cofree genuine G-spectrum on X*, also known as

$$F(EG_+, X).$$

We know from other models of G-spectra that for any subgroup $H \leq G$,

$$(EG_+ \wedge X)^H \simeq X_{hH},\ F(EG_+, X)^H \simeq X^{hH}.$$

It would be desirable, however, to have a proof of these facts internal to our framework. The following lemma is a more general version of this result:

Lemma 2.28. Suppose $\mathcal{M}$ is an orbital ∞-category and $i : \mathcal{T} \hookrightarrow \mathcal{M}$ is the inclusion of an upwardly closed subcategory. Let $\mathbf{C}$ be a semiadditive ∞-category with all colimits, and let $B \in \mathbf{Mack}(\mathcal{T}, \mathbf{C})$ be a Mackey functor. Then for any $Y \in \mathcal{M}$,

$$i_! B(Y) \simeq \operatorname*{colim}_{\mathcal{M}^{\amalg}_{/Y} \times_{\mathcal{M}^{\amalg}} \mathcal{T}^{\amalg}} B.$$

Proof. For now, we content ourselves with a sketched proof and leave the details as an exercise. This result will be assumed in some examples in Section 3 but will not feature integrally in the results of the paper.

For the sake of avoiding the ambiguity that can precipitate from the use of overcategory notation, we clarify our notation. Write

$$\mathcal{T}^{\amalg}_{/Y} = \mathcal{M}^{\amalg}_{/Y} \times_{\mathcal{M}^{\amalg}} \mathcal{T}^{\amalg}$$

and

$$(A^{eff}(\mathcal{T}))_{/Y} = (A^{eff}(\mathcal{M}))_{/Y} \times_{A^{eff}(\mathcal{M})} A^{eff}(\mathcal{T}).$$

Then we have

$$i_! B(Y) \simeq \operatorname*{colim}_{(A^{eff}(\mathcal{T}))_{/Y}} B.$$

The objects of $(A^{eff}(\mathcal{T}))_{/Y}$ are of the form

$$\begin{array}{ccc} & T' & \\ {\scriptstyle f}\swarrow & & \searrow \\ T & & Y. \end{array}$$

We can define a functor $V : \mathcal{T}^{\amalg}_{/Y} \to (A^{eff}(\mathcal{T}))_{/Y}$ by

$$V(T \to Y) = \left(\begin{array}{ccc} & T & \\ /\!\!/ & & \searrow \\ T & & Y \end{array} \right).$$

The essential image of V comprises those diagrams for which $f : T' \to T$ is an equivalence, and it can be shown that V is homotopic to the inclusion of the full subcategory $(\overline{A^{eff}(\mathcal{M})})_{/Y}$ spanned by such diagrams. Moreover, the inclusion of $(\overline{A^{eff}(\mathcal{M})})_{/Y}$ has a left adjoint ϕ with

$$\phi \left(\begin{array}{ccc} & T' & \\ \swarrow & & \searrow \\ T & & Y \end{array} \right) \simeq \left(\begin{array}{ccc} & T' & \\ /\!\!/ & & \searrow \\ T' & & Y \end{array} \right).$$

Thus this inclusion is cofinal, which yields the result. $\square$

Corollary 2.29. Suppose $\mathcal{M}$ is an epiorbital category and $X \in \mathcal{M}$ is a maximal object. Let

$$i_X : A^{eff}(\mathcal{G}_X) \to A^{eff}(\mathcal{M})$$

be the inclusion, let $\mathbf{C}$ be a semiadditive ∞-category with all colimits, and let $B \in \mathbf{Mack}(\mathcal{G}_X, \mathbf{C})$ be a Mackey functor, which by Theorem 2.27 is uniquely determined by $B(X)$ regarded as an object of $\mathbf{C}$ with $\mathrm{Aut}(X)$-action. Then for any $Y \in \mathcal{M}$,

$$(i_X)_! B(Y) \simeq (B(X) \times \mathrm{Hom}_{\mathcal{M}}(X, Y))_{h\mathrm{Aut}(X)}.$$

In particular, if Y is a final object,

$$(i_X)_! B(Y) \simeq B(X)_{h\mathrm{Aut}(X)}.$$

□

Definition 2.30. Let $\mathcal{M}$ be an EOC and $X \in \mathcal{M}$ an object. The *Taylor coefficient at* X functor is the functor $D^X : \mathbf{Mack}(\mathcal{M}, \mathbf{C}) \to \mathrm{Fun}(\mathcal{G}_X, \mathbf{C})$ given by $i_X^* \circ \Phi^X$.

Definition 2.31. Let $\mathcal{M}^\sim$ be the maximal subgroupoid of $\mathcal{M}$ and define the *Taylor sequence* functor

$$D : \mathbf{Mack}(\mathcal{M}, \mathbf{C}) \to \mathrm{Fun}(\mathcal{M}^\sim, \mathbf{C})$$

by

$$\bigvee_{[X]} D^X.$$

We'll now enforce the hypothesis that $\mathbf{C}$ is stable for the remainder of the section. This allows us to state the following important proposition, which is a generalization of the "norm cofibration sequence" from equivariant stable homotopy theory:

Theorem 2.32. Let $\mathcal{N}$ be a downwardly closed subcategory of an orbital ∞-category $\mathcal{M}$ and $\mathcal{T}$ its upwardly closed complement. Denote the restriction $A^{eff}(i_{\mathcal{T}})^*$ and the left Kan extension $A^{eff}(i_{\mathcal{T}})_!$ respectively by $\Pi^{\mathcal{T}}$ and $\Gamma^{\mathcal{T}}$. There's a cofiber sequence of functors $\mathbf{Mack}(\mathcal{M}, \mathbf{C}) \to \mathbf{Mack}(\mathcal{M}, \mathbf{C})$

$$\Gamma^{\mathcal{T}} \Pi^{\mathcal{T}} \xrightarrow{\epsilon} \mathrm{Id} \xrightarrow{\eta} \Xi^{\mathcal{N}} \Phi^{\mathcal{N}},$$

where ϵ and η are the counit and unit of their respective adjunctions.

Theorem 2.32 has the following important equivalent form, whose theme is that a Mackey functor contains no secret data not detected by its values:

Corollary 2.33. $\Xi^{\mathcal{N}}$ is fully faithful, and its essential image is the category $\mathbf{Mack}_{\mathcal{N}}(\mathcal{M}, \mathbf{C})$ of Mackey functors on $\mathcal{M}$ supported on $\mathcal{N}$.

Proof. If $M \in \mathbf{Mack}_{\mathcal{N}}(\mathcal{M}, \mathbf{C})$, then evidently $\Pi^{\mathcal{T}} M$ is zero, and so the cofiber sequence of Theorem 2.32 collapses to an equivalence

$$M \simeq \Xi^{\mathcal{N}} \Phi^{\mathcal{N}} M,$$

which establishes the essential image of $\Xi^{\mathcal{N}}$.

Since $\Xi^{\mathcal{N}}$ is visibly conservative, it follows for $N \in \mathbf{Mack}(\mathcal{N}, \mathbf{C})$, setting $M = \Xi^{\mathcal{N}} N$, that

$$N \simeq \Phi^{\mathcal{N}} \Xi^{\mathcal{N}} N,$$

and the full faithfulness of $\Xi^{\mathcal{N}}$ follows by adjunction. □

Remark 2.34. Observe that Corollary 2.33 also implies Theorem 2.32. Indeed, it follows abstractly that the functor

$$M \mapsto \mathrm{cof}(\epsilon_M)$$

is the localization into $\mathbf{Mack}_{\mathcal{N}}(\mathcal{M}, \mathbf{C})$. On the other hand, assuming that $\Xi^{\mathcal{N}}$ is fully faithful, $\Xi^{\mathcal{N}} \Phi^{\mathcal{N}}$ is the localization into its essential image. By Corollary 2.33, these two localizations coincide, yielding 2.32.

Definition 2.35. Let $\mathcal{D}A(\mathcal{M})$ denote the nonabelian derived category of $A^{eff}(\mathcal{M})$: the category of product-preserving functors $A^{eff}(\mathcal{M}) \to \mathbf{Top}$ [Lur09, Definition 5.5.8.8]. Equivalently, $\mathcal{D}A(\mathcal{M})$ is the category of Mackey functors on $\mathcal{M}$ valued in the category **CMon** of commutative monoid spaces (see, for instance, [Gla16, Remark 2.7]).

Let $\mathbf{C}$ and $\mathbf{D}$ be presentable ∞-categories. Recall that the category of coproduct-preserving functors from $\mathbf{C}$ to $\mathbf{D}$ is denoted $\mathrm{Fun}^{\amalg}(\mathbf{C}, \mathbf{D})$, and that the category of functors from $\mathbf{C}$ to $\mathbf{D}$ that preserve all colimits is denoted $\mathrm{Fun}^{L}(\mathbf{C}, \mathbf{D})$. Now for presentable $\mathbf{C}$, by [Lur09, Proposition 5.5.8.15], there's an equivalence of categories

$$\mathrm{Fun}^{L}(\mathcal{D}A(\mathcal{M}), \mathbf{C}) \simeq \mathrm{Fun}^{\amalg}(A^{eff}(\mathcal{M}), \mathbf{C}).$$

If $\mathbf{C}$ is, in addition, semiadditive, this can be written as an equivalence

$$\mathrm{Fun}^{L}(\mathcal{D}A(\mathcal{M}), \mathbf{C}) \simeq \mathbf{Mack}(\mathcal{M}, \mathbf{C}). \qquad (*)$$

Lemma 2.36. Theorem 2.32 holds when $\mathbf{C} = \mathbf{CMon}$.

Before proving Lemma 2.36, let's deduce Theorem 2.32 from Lemma 2.36. We know

$$\Phi^{\mathcal{N}} : \mathcal{D}A(\mathcal{M}) \to \mathcal{D}A(\mathcal{N})$$

is a localization. Under the equivalence of $(*)$, $\Xi^{\mathcal{N}}$ corresponds to

$$(\Phi^{\mathcal{N}})^* : \mathrm{Fun}^{L}(\mathcal{D}A(\mathcal{N}), \mathbf{C}) \to \mathrm{Fun}^{L}(\mathcal{D}A(\mathcal{M}), \mathbf{C}),$$

and by the universal property of a localization, $(\Phi^{\mathcal{N}})^*$ is fully faithful, and objects of its essential image are functors which map $\Phi^{\mathcal{N}}$-equivalences to equivalences.

Now here's where we use the stability of $\mathbf{C}$: since a morphism in a stable ∞-category is an equivalence if and only if its fiber is zero, the objects of the essential image of $(\Phi^{\mathcal{N}})^*$ are equivalently those functors which map objects in the essential image of

$$\Gamma^{\mathcal{T}} : \mathcal{D}A(\mathcal{T}) \to \mathcal{D}A(\mathcal{M})$$

to $0 \in \mathbf{C}$. But since the equivalence $(*)$ is given by the Yoneda embedding, and since the diagram

$$\begin{array}{ccc} A^{eff}(\mathcal{T}) & \xrightarrow{\sim} & \mathcal{D}A(\mathcal{T}) \\ {\scriptstyle A^{eff}(i_{\mathcal{T}})}\downarrow & & \downarrow{\scriptstyle \Gamma^{\mathcal{T}}} \\ A^{eff}(\mathcal{M}) & \xrightarrow{\sim} & \mathcal{D}A(\mathcal{M}) \end{array}$$

commutes, these correspond under $(*)$ to the objects of $\mathbf{Mack}_{\mathcal{N}}(\mathcal{M}, \mathbf{C})$. This proves Corollary 2.33, and therefore Theorem 2.32.

Proof of Lemma 2.36. The proof of this lynchpin lemma is very technical, and so we've relegated it to Appendix B. It's not required reading for those who don't care to learn to make a very specific kind of sausage, but we note that it's our main point of contact with the combinatorics of the effective Burnside category. □

Let $\mathcal{M}$ be a EOC. For each $X \in \mathcal{M}$, we may define functors

$$R^X = \Xi^X \circ (i_X)_*$$

and

$$L^X = \Xi^X \circ (i_X)_!,$$

where $(i_X)_!$ and $(i_X)_*$ are left and right Kan extension respectively. Observe that $(i_X)_!$ and $(i_X)_*$ are fully faithful, since they're Kan extensions along a fully faithful functor. Since we've already seen that Ξ^X is fully faithful, we conclude that both L^X and R^X are fully faithful. Moreover, R^X is right adjoint to the Taylor coefficient functor D^X.

Similarly, we can define

$$R = \bigvee_{[X]} R^X$$

and

$$L = \bigvee_{[X]} L^X$$

and R is right adjoint to the Taylor sequence functor D.

Proposition 2.37. *L is a section of D; that is, $D \circ L$ is homotopic to the identity.*

Proof. We'll use induction on the number of isomorphism classes of objects in $\mathcal{M}$. If $\mathcal{M}$ is a groupoid, both L and D are already the identity. In general, let X be a maximal object of $\mathcal{M}$. It's clear that $D \circ L$ is homotopic to the identity when restricted to $\mathcal{G}_X$.

Then the morphism

$$(i_X)_!(i_X)^* L \to L$$

is equivalent to the summand inclusion

$$L^X \to \bigvee_{[Y]} L^Y$$

and therefore by Theorem 2.32, we have a cofiber sequence

$$L^X \to L \to \Phi^{\mathcal{M}_{<X}} L$$

which shows that the left square in the diagram

$$\begin{array}{ccccc} \mathrm{Fun}(\mathcal{M}^{\sim}, \mathbf{C}) & \xrightarrow{L} & \mathbf{Mack}(\mathcal{M}, \mathbf{C}) & \xrightarrow{D} & \mathrm{Fun}(\mathcal{M}^{\sim}, \mathbf{C}) \\ \downarrow & & \downarrow{\scriptstyle \Phi^{\mathcal{M}_{<X}}} & & \downarrow \\ \mathrm{Fun}(\mathcal{M}^{\sim}_{<X}, \mathbf{C}) & \xrightarrow{L} & \mathbf{Mack}(\mathcal{M}_{<X}, \mathbf{C}) & \xrightarrow{D} & \mathrm{Fun}(\mathcal{M}^{\sim}_{<X}, \mathbf{C}) \end{array}$$

commutes. The right square commutes by construction, and the bottom composite is homotopic to the identity by the induction hypothesis. By circumnavigating the diagram, we conclude that $D \circ L$ is homotopic to the identity when restricted to $\mathcal{G}_Y$ for any $Y \neq X$. □

The following is our Arone-Ching theorem in its general form.

Theorem 2.38. Let $\mathcal{M}$ be an epiorbital category. Then the adjunction (D, R) is comonadic.

Proof. (D, R) is comonadic if and only if the natural transformation

$$t : \mathrm{Id} \to \mathbf{Tot}(\mathrm{Cobar}(R, DR, D))$$

is an equvalence. We'll closely follow Arone and Ching's proof in [AC15]. This involves showing, for each downwardly-closed subcategory $\mathcal{N}$ of $\mathcal{M}$, that the natural map

$$t^{\mathcal{N}} : \Xi^{\mathcal{N}} \Phi^{\mathcal{N}} \to \mathbf{Tot}(\Xi^{\mathcal{N}} \Phi^{\mathcal{N}} \mathrm{Cobar}(R, DR, D))$$

is an equivalence, by induction on the number of isomorphism classes of objects in $\mathcal{N}$. Since $\Xi^{\mathcal{M}} \Phi^{\mathcal{M}}$ is the identity functor, this will give the result.

So assume that $t^{\mathcal{P}}$ is an equivalence for all $\mathcal{P}$ with at most k isomorphism classes of objects, and suppose $\mathcal{N}$ has $k+1$ isomorphism classes of objects. Let X be a maximal object of $\mathcal{N}$ and let $\mathcal{N}' = \mathcal{N} \setminus \mathcal{G}_X$ be the result of removing the isomorphism class of X. The cofiber sequence of Theorem 2.32 gives a cofiber sequence of functors

$$L^X D^X \to \Xi^{\mathcal{N}} \Phi^{\mathcal{N}} \to \Xi^{\mathcal{N}'} \Phi^{\mathcal{N}'},$$

which in turn gives a map of cofiber sequences

$$\begin{array}{ccc}
L^X D^X & \xrightarrow{t^X} & \mathbf{Tot}(L^X D^X \mathrm{Cobar}(R, DR, D)) \\
\downarrow & & \downarrow \\
\Xi^{\mathcal{N}} \Phi^{\mathcal{N}} & \xrightarrow{t^{\mathcal{N}}} & \mathbf{Tot}(\Xi^{\mathcal{N}} \Phi^{\mathcal{N}} \mathrm{Cobar}(R, DR, D)) \\
\downarrow & & \downarrow \\
\Xi^{\mathcal{N}'} \Phi^{\mathcal{N}'} & \xrightarrow{t^{\mathcal{N}'}} & \mathbf{Tot}(\Xi^{\mathcal{N}'} \Phi^{\mathcal{N}'} \mathrm{Cobar}(R, DR, D)).
\end{array}$$

By the induction hypothesis, $t^{\mathcal{N}'}$ is an equivalence, so it'll suffice to show that t^X is an equivalence. This also starts the induction, since $t^{\mathcal{N}} = t^X$ if $\mathcal{N} = \mathcal{G}_X$ is a connected groupoid. But now we observe that

$$D^X = ev_X D$$

and so

$$\begin{aligned}
\mathbf{Tot}(L^X D^X \mathrm{Cobar}(R, DR, D)) &\simeq \mathbf{Tot}(L^X ev_X D \mathrm{Cobar}(R, DR, D)) \\
&\simeq \mathbf{Tot}(L^X ev_X \mathrm{Cobar}(DR, DR, D)) \\
&\simeq L^X ev_X D \\
&\simeq L^X D^X
\end{aligned}$$

by the usual extra codegeneracy argument. This completes the proof. □

The next section aims to characterize the comonad DR.

3 Categories stratified along a poset

The categories $\mathbf{Mack}(\mathcal{M})$ for $\mathcal{M}$ a EOC, along with many other categories occuring in nature, share a significant structural property: any object of $\mathbf{Mack}(\mathcal{M})$ can be torn open by a series of fracture squares. More precisely, suppose that $\mathcal{N}$ is a downwardly-closed subcategory, $\mathcal{T}$ is its upwardly-closed complement and $X \in \mathbf{Mack}(\mathcal{M})$. Then we'll see that there's a pullback square

$$\begin{array}{ccc}
X & \longrightarrow & (i_{\mathcal{T}})_*(i_{\mathcal{T}})^* X \\
\downarrow & & \downarrow \\
\Phi^{\mathcal{N}} X & \longrightarrow & \Phi^{\mathcal{N}}(i_{\mathcal{T}})_*(i_{\mathcal{T}})^* X
\end{array}$$

To build a theory of how X might be recovered from such data, it'll be helpful to widen our scope. First it's important to advertise a potential point of significant notational confusion.

Warning 3.1. When we regard a poset as a category in this paper, we will use the *opposite* of the usual convention that there is a morphism from x to y if $x \leq y$. For us, the space of morphisms from x to y will be contractible if $x \geq y$ and empty otherwise. We adopt this strange convention in order to preserve intuitions about size of objects in our chief motivating examples of posets: the posets of isomorphism classes of objects of the EOCs $\mathcal{O}_G$ and $\mathcal{F}_s^{\leq n}$.

Definition 3.2. Let $\mathcal{P}$ be a poset. An *interval* in $\mathcal{P}$ is a subset $I \subseteq \mathcal{P}$ such that whenever $x, y \in I$ and $x < z < y$, we have $z \in I$. If $\mathcal{P}$ is any poset, then we denote by $\mathcal{I}_{\mathcal{P}}$ be the poset of intervals in $\mathcal{P}$ ordered by inclusion. If I and J are a pair of intervals, we'll write $I \prec J$ if $I \cap J = \emptyset$ and there is no pair $(i \in I, j \in J)$ with $i > j$.

Note that the relation $\prec$ is *not* a partial order: for example, if $p, q \in \mathcal{P}$ are incomparable, then both $\{p\} \prec \{q\}$ and $\{q\} \prec \{p\}$.

Definition 3.3. Suppose $\mathbf{C}$ is a stable ∞-category. Let $\mathcal{E}_{\mathbf{C}}$ be the poset of stable reflective subcategories of $\mathbf{C}$, ordered by inclusion; equivalently, $\mathcal{E}_{\mathbf{C}}$ is the opposite of the poset of exact localizations of $\mathbf{C}$. Let $\mathbf{P}$ be a poset. Then a *pre-stratification of* $\mathbf{C}$ *along* $\mathcal{P}$ is a map of posets

$$\mathfrak{S} : \mathcal{I}_{\mathcal{P}} \to \mathcal{E}_{\mathbf{C}}.$$

Before we give the criteria that will qualify a pre-stratification as a stratification, it'll be useful to record an elementary fact about localizations.

Lemma 3.4. Given two localizations $\mathcal{L}_1$ and $\mathcal{L}_2$ on a stable ∞-category $\mathbf{C}$ such that $\mathcal{L}_1\mathcal{L}_2 = 0$, the following conditions are equivalent:

(1) The natural diagram

$$\begin{array}{ccc} \mathrm{id} & \longrightarrow & \mathcal{L}_1 \\ \downarrow & & \downarrow \\ \mathcal{L}_2 & \longrightarrow & \mathcal{L}_2\mathcal{L}_1 \end{array}$$

is a pullback square.

(2) The containment $\mathcal{L}_2\mathbf{C} \subseteq \ker(\mathcal{L}_1)$ is an equality.

(3) $\mathcal{L}_1$ and $\mathcal{L}_2$ are jointly conservative.

Proof. The implication (1) $\Rightarrow$ (3) is obvious. We'll prove (3) $\Rightarrow$ (2) $\Rightarrow$ (1). Suppose that $\mathcal{L}_1$ and $\mathcal{L}_2$ are jointly conservative; then if some

$$X \in \ker(\mathcal{L}_1) \setminus \mathcal{L}_2\mathbf{C},$$

the localization map $X \to \mathcal{L}_2 X$ is a non-equivalence which becomes an equivalence after applying either $\mathcal{L}_1$ or $\mathcal{L}_2$, establishing (2). If we now denote by $\mathcal{C}$ the fiber of id $\to \mathcal{L}_1$, then

$$\mathrm{im}\ \mathcal{C} \subseteq \mathcal{L}_2\mathbf{C}$$

(in fact, $\mathcal{C}$ is the coreflection into $\mathcal{L}_2\mathbf{C}$). Now taking horizontal fibers in the square diagram gives the morphism

$$\mathcal{C} \to \mathcal{L}_2\mathcal{C}$$

which is an equivalence, establishing (1). □

Definition 3.5. In the notation of Definition 3.3, let

$$\mathcal{L}_I : \mathbf{C} \to \mathbf{C}$$

be the localization functor corresponding to $\mathfrak{S}(I)$. Then we call $\mathfrak{S}$ a *stratification of* $\mathbf{C}$ *along* $\mathcal{P}$ if the following conditions hold:

(1) $\mathfrak{S}(\mathcal{P}) = \mathbf{C}$,

(2) if $I_2 \prec I_1$, then $\mathcal{L}_{I_1}\mathcal{L}_{I_2} = 0$,

(3) and if $I = I_1 \coprod I_2$, then $\mathcal{L}_{I_1}$ and $\mathcal{L}_{I_2}$, viewed as localization functors on $\mathfrak{S}(I)$, satisfy the equivalent conditions of Lemma 3.4.

Remark 3.6. Since $\emptyset \prec \emptyset$, axiom (2) implies that $\mathcal{S}(\emptyset) = \{0\}$.

Remark 3.7. It follows from the latter two axioms that if $I = I_1 \coprod I_2$ and $I_2 \prec I_1$, then $\mathfrak{S}(I)$ is a *recollement* of $\mathfrak{S}(I_2)$ and $\mathfrak{S}(I_1)$ in the sense of [Lur12, Definition A.8.1].

Remark 3.8. For most of this section we'll assume that $\mathcal{P}$ is finite, but our main result generalizes easily to certain infinite posets (Definition 3.30). n will usually denote the cardinality of $\mathcal{P}$. We'll also assume that $\mathcal{P}$ is connected; it's easy to see that a category stratified along a disconnected poset decomposes naturally as a direct sum of categories stratified along the connected components.

Next we'll see some examples of stratifications. Suppose $\mathbf{C}$ is a presentable symmetric monoidal stable ∞-category whose tensor product preserves colimits in each variable, so that we can talk about the homological localization with respect to an object $E \in \mathbf{C}$ [Bou79]:

Recollection 3.9. An object $F \in \mathbf{C}$ is called *E-acyclic* if $E \otimes F$ is zero. An object $G \in \mathbf{C}$ is called *E-local* if $\mathrm{Map}(F, G)$ is contractible for any E-acyclic F. The E-local objects of $\mathbf{C}$ form a reflective subcategory $\mathbf{L}_E$, with associated localization functor $\mathcal{L}_E$.

Let $\mathcal{P}$ be a poset and suppose we have an object K_p for each $p \in \mathcal{P}$ such that any K_p-local object is K_q-acyclic unless $p \geq q$. We can define a pre-stratification $\mathfrak{S}_{K_\bullet}$ of $\mathbf{C}$ along $\mathcal{P}$ by assigning to I the category of objects which are local with respect to the object $\bigvee_{i \in I} K_i$.

Proposition 3.10. $\mathfrak{S}_{K_\bullet}$ is a stratification of $\mathfrak{S}_{K_\bullet}(\mathcal{P}) = \mathbf{L}_{\bigvee_{p \in \mathcal{P}} K_p}$.

Proof. The proof will consist of two lemmas, and will use induction on the cardinality of $\mathcal{P}$.

Lemma 3.11. Suppose E and F are such that any E-local object is F-acyclic. Then the square of functors

$$\begin{array}{ccc} \mathcal{L}_{E\vee F} & \xrightarrow{f} & \mathcal{L}_F \\ \Big\downarrow{\scriptstyle g} & & \Big\downarrow{\scriptstyle h} \\ \mathcal{L}_E & \xrightarrow{i} & \mathcal{L}_E\mathcal{L}_F \end{array}$$

is a pullback square.

Proof. This fact is folklore, and cases of it go back to Bousfield and further. The proof, which we now give, is simple.

g and h are both E-localizations, and therefore E-equivalences, and so the total fiber of the square is E-acyclic. On the other hand, f is an F-equivalence, and so is i because its source and target are both F-acyclic. Thus the total fiber of the square is F-acyclic, and so $E \vee F$-acyclic. But everything in the square is $E \vee F$-local, so the total fiber must also be $E \vee F$-local, and hence zero. □

Lemma 3.12. Suppose $\mathcal{I} \subseteq \mathcal{P}$ is a proper interval and $p \in \mathcal{P}$ is such that $\mathcal{I} \prec \{p\}$. Then any object $E \in \mathfrak{S}_{K_\bullet}(\mathcal{I})$ is K_p-acyclic.

Proof. The proof will use Theorem 3.21 (spoilers). By the induction hypothesis, $\mathfrak{S}_{K_\bullet}$ restricts to a stratification of $\mathfrak{S}_{K_\bullet}(\mathcal{I})$ along $\mathcal{I}$. Then the proof of Theorem 3.21 expresses E as a finite limit of objects which are K_i-local for some $i \in \mathcal{I}$, and thus K_p-acyclic. Therefore E is K_p-acyclic. □

□

Remark 3.13. For this class of stratifications, in the case where $\mathcal{P}$ is totally ordered, a theorem similar to Theorem 3.21 has appeared previously in [ACB14].

We'll now give a pair of quick applications of Proposition 3.10.

Example 3.14. Fix a prime p. Then the Morava K-theory spectra $K(0), \cdots, K(n)$ give rise to a stratification of the category of $\bigvee_{i=0}^n K(i)$-local spectra along $(D^n)^{\mathrm{op}}$. (Recall that a spectrum is $\bigvee_{i=0}^n K(i)$-local if and only if it's local with respect to the Morava E-theory E_n.) The pullback squares in this stratification include the famous *chromatic fracture squares*

$$\begin{array}{ccc} \mathcal{L}_{E_n} & \longrightarrow & \mathcal{L}_{K_n} \\ \Big\downarrow & & \Big\downarrow \\ \mathcal{L}_{E_{n-1}} & \longrightarrow & \mathcal{L}_{E_{n-1}}\mathcal{L}_{K_n} \end{array}$$

which are the subject of Hopkins' chromatic splitting conjecture [Hov93].

Example 3.15. Let X be a scheme; let $(U_i)_{0\leq i\leq n}$ be locally closed subschemes of X such $U_0 = X$, U_1 is an open subscheme of X, and for $i \geq 2$, U_i is an open subscheme of $U_{i-1} \setminus U_{i-2}$. We say that the U_i form a *stratification* of X.

Let $\mathbf{QC}(X)$ be the stable ∞-category of quasicoherent complexes on $\mathbf{X}$. Then the structure sheaves $\mathcal{O}_{U_i} \in \mathbf{QC}(X)$, $1 \leq i \leq n$, satisfy the hypotheses of Proposition 3.10 and so form a stratification of $\mathcal{L}_{\bigoplus_{i=1}^n \mathcal{O}_{U_i}}\mathbf{QC}(X)$ along Δ^{n-1}. In the case where

$$\bigcup_{i=1}^n U_i = X,$$

this is a stratification of $\mathbf{QC}(X)$ itself.

Our other main source of examples of stratifications comes from the theory developed in Section 2. We'll be able to say something about orbital ∞-categories and substantially more about epiorbital categories.

Let $\mathcal{M}$ be an orbital ∞-category, let $\mathcal{N}$ be a downwardly-closed subcategory of $\mathcal{M}$, and let $\mathcal{T}$ be its upwardly-closed complement. If $\mathbf{C}$ is a stable ∞-category with all limits and colimits, let $\mathbf{Mack}(\mathcal{M};\mathbf{C})$ be the category of $\mathbf{C}$-valued Mackey functors on $\mathcal{M}$ (Definition 2.16). We define a pre-stratification $\mathfrak{S}_{\mathcal{M}}$ of $\mathbf{Mack}(\mathcal{M},\mathbf{C})$ along Δ^1 as follows:

- $\mathfrak{S}_{\mathcal{M}}(\Delta^1) = \mathbf{Mack}(\mathcal{M},\mathbf{C})$,
- $\mathfrak{S}_{\mathcal{M}}(\{1\})$ is the category $\mathbf{Mack}^{\mathcal{T}}(\mathcal{M},\mathbf{C})$ of Mackey functors in the essential image of the right Kan extension from $\mathbf{Mack}(\mathcal{T},\mathbf{C})$,
- $\mathfrak{S}_{\mathcal{M}}(\{0\})$ is the category $\mathbf{Mack}_{\mathcal{N}}(\mathcal{M},\mathbf{C})$ of Mackey functors supported on $\mathcal{N}$ (see Corollary 2.33).

Proposition 3.16. $\mathfrak{S}_{\mathcal{M}}$ is a stratification.

Proof. We must show that the square

$$\begin{array}{ccc} \mathrm{id}_{\mathbf{Mack}(\mathcal{M},\mathbf{C})} & \longrightarrow & \mathcal{L}_1 \\ \downarrow & & \downarrow \\ \mathcal{L}_0 & \longrightarrow & \mathcal{L}_0\mathcal{L}_1 \end{array}$$

is a pullback square of endofunctors. But by taking vertical fibers and applying Theorem 2.32, we're reduced to showing that the natural map

$$\Gamma^{\mathcal{T}}\Pi^{\mathcal{T}} \to \Gamma^{\mathcal{T}}\Pi^{\mathcal{T}}\mathcal{L}_1$$

is an equivalence, which is obvious. □

Now suppose $\mathcal{M}$ is epiorbital, and let $\mathcal{P}_{\mathcal{M}}$ be the poset of isomorphism classes in $\mathcal{M}$ (Definition 2.2).

Definition 3.17. We define a pre-stratification $\mathfrak{S}_{\mathcal{M}}$ on $\mathbf{Mack}(\mathcal{M};\mathbf{C})$ as follows. If $I \subseteq \mathcal{P}_{\mathcal{M}}$ is any interval, let $\mathcal{I}$ be the corresponding full subcategory of $\mathcal{M}$. If I is downwardly-closed, then we define

$$\mathfrak{S}_{\mathcal{M}}(I) = \mathbf{Mack}_{\mathcal{I}}(\mathcal{M};\mathbf{C}) \qquad \text{(Corollary 2.33)}$$

If $J \subseteq \mathcal{P}_{\mathcal{M}}$ is upwardly closed, then let $\mathbf{Mack}^{\mathcal{J}}(\mathcal{M},\mathbf{C})$ be the essential image of the right Kan extension

$$A^{eff}(i_{\mathcal{J}})_* : \mathbf{Mack}(\mathcal{J},\mathbf{C}) \to \mathbf{Mack}(\mathcal{M},\mathbf{C}).$$

We define

$$\mathfrak{S}_{\mathcal{M}}(J) = \mathbf{Mack}^{\mathcal{J}}(\mathcal{M},\mathbf{C}).$$

If $I \subseteq \mathcal{P}_{\mathcal{M}}$ is any interval, then we can write

$$I = I_+ \cap I_-$$

where I_+ is the smallest upwardly-closed set containing I and I_- is, likewise, the smallest downwardly-closed set containing I. Then we define

$$\mathfrak{S}_{\mathcal{M}}(I) = \mathbf{Mack}^{\mathcal{I}_+}(\mathcal{M},\mathbf{C}) \cap \mathbf{Mack}_{\mathcal{I}_-}(\mathcal{M},\mathbf{C}).$$

Proposition 3.18. $\mathfrak{S}_{\mathcal{M}}$ is a stratification of $\mathbf{Mack}(\mathcal{M},\mathbf{C})$ along $\mathcal{P}_{\mathcal{M}}$.

Proof. Clearly

$$\mathfrak{S}_{\mathcal{M}}(\mathcal{P}_{\mathcal{M}}) = \mathbf{Mack}(\mathcal{M},\mathbf{C}).$$

We must verify (3) in Definition 3.5. Let $\mathcal{I},\mathcal{I}_1,\mathcal{I}_2$, be the full subcategories of $\mathcal{M}$ corresponding respectively to I, I_1, I_2, and let $\mathcal{D}$ be the smallest downwardly-closed subcategory of $\mathcal{M}$ containing $\mathcal{I}$. Then by passing to $\mathbf{Mack}_{\mathcal{D}}(\mathcal{M},\mathbf{C})$ if necessarily, we may assume that I_1 is upwardly-closed.

Assume for a moment that $I = \mathcal{P}_{\mathcal{M}}$. Then, as in the proof of Proposition 3.16, we conclude by taking fibers vertically and invoking Theorem 2.32. In general, we note that

$$I_2 = I \cap (\mathcal{P}_{\mathcal{M}} \setminus I_1).$$

We know that the natural diagram

$$\begin{array}{ccc} \mathrm{id} & \longrightarrow & \mathcal{L}_{I_1} \\ \downarrow & & \downarrow \\ \mathcal{L}_{\mathcal{P}_{\mathcal{M}}\setminus I_1} & \longrightarrow & \mathcal{L}_{\mathcal{P}_{\mathcal{M}}\setminus I_1}\mathcal{L}_{I_1} \end{array}$$

is a pullback square, and applying $\mathcal{L}_I$ to the entire square gives the result. □

We'll now start setting up for our main result on the reconstruction of objects in a stratified category from their atomic localizations.

Definition 3.19. Let $\mathcal{P}$ be a finite poset. Define $\mathbb{P}(\mathcal{P})$ to be the poset of nonempty subsets $T = \{i_1, i_2, \cdots, i_k\}$ of $\mathcal{P}$, ordered by reverse inclusion.

Definition 3.20. Let $(\mathbf{C}, \mathfrak{S})$ be a stable ∞-category stratified along $\mathcal{P}$. We define an ∞-category $\mathbf{C}^{\mathfrak{S}}$ as the full subcategory of $\mathrm{Fun}(\mathbb{P}(\mathcal{P}), \mathbf{C})$ spanned by those functors

$$F : \mathbb{P}(\mathcal{P}) \to \mathbf{C}$$

such that

- for each $T \in \mathbb{P}(\mathcal{P})$ and for each minimal element $t \in T$, $F(T)$ is in $\mathfrak{S}(\{t\})$;
- if e is an edge of $\mathbb{P}(\mathcal{P})$ of the form $T \to T \cup \{p\}$ where $\{p\} \prec T$, then $F(e)$ exhibits $F(T \cup \{p\})$ as the $\mathfrak{S}(\{p\})$-localization of $F(T)$.

The following, describing how objects of a stratified category can be assembled using higher fracture squares, is the main theorem of this section.

Theorem 3.21. There's an equivalence of categories

$$\mathfrak{d} : \mathbf{C} \to \mathbf{C}^{\mathfrak{S}}.$$

This equivalence will be constructed as an explicit zigzag in the course of the proof.

The first step is to realize that we don't have enough posets, and define some more posets.

Definition 3.22. Let $\mathbb{P}'(\mathcal{P})$ be the set whose elements are nonempty sets $\{I_1, \cdots, I_k\}$ of nonempty, disjoint intervals in $\mathcal{P}$ such that for each pair of indices i, j, either $I_i \prec I_j$ or $I_j \prec I_i$. We'll put a partial order on $\mathbb{P}'(\mathcal{P})$ by letting

$$\{I_1, \cdots, I_k\} \geq \{J_1, \cdots, J_l\}$$

if there exist distinct indices $(i_1, \cdots, i_k)$ such that $J_{i_j} \subseteq I_j$ for each j.

If $T \in \mathbb{P}'(\mathcal{P})$ and $I \in T$, then we'll call I *$\prec$-minimal* if for each $J \in T$ with $J \neq I$, $I \prec J$. This doesn't necessarily imply that there is no $J \in T$ such that $J \prec I$. However, since $\prec$ is transitive, each $T \in \mathbb{P}'(\mathcal{P})$ has at least one $\prec$-minimal element.

Here's a way of "coordinatizing" a poset.

Definition 3.23. A *threading* of a finite poset $\mathcal{P}$ is a filtration

$$\emptyset = \mathcal{P}_{\leq 0} \subseteq \mathcal{P}_{\leq 1} \subseteq \cdots \mathcal{P}_{\leq n} = \mathcal{P}$$

such that for each i, $\mathcal{P}_{\leq i}$ is downwardly closed, and

$$|\mathcal{P}_{\leq i}| = i.$$

We'll fix, once and for all, a threading on $\mathcal{P}$.

Definition 3.24. Let $\mathbb{P}^m(\mathcal{P})$ be the subset of $\mathbb{P}'(\mathcal{P})$ containing those sets

$$T = \{I_1, \cdots, I_k\}$$

such that for each I_i, either $|I_i| = 1$ or

$$I_i = \mathcal{P}_{\leq i} \text{ for some } i \leq m.$$

In particular, at most one of the I_i may have cardinality > 1, and if this occurs then I_i must be a $\prec$-minimal element of T.

There's an obvious isomorphism $\mathbb{P}^1(\mathcal{P}) \cong \mathbb{P}(\mathcal{P})$.

Definition 3.25. Let $\mathbf{C}_m^{\mathfrak{S}}$ be the full subcategory of $\mathrm{Fun}(\mathbb{P}^m(\mathcal{P}))$ spanned by those functors

$$F : \mathbb{P}^m(\mathcal{P}) \to \mathbf{C}$$

such that

- for each $T = \{I_1, \cdots, I_k\} \in \mathbb{P}^m(\mathcal{P})$ and for each I_i that is $\prec$-minimal in T, $F(T) \in \mathfrak{S}(I_i)$;
- if $e : T_1 \to T_2$ is an edge of $\mathbb{P}^m(\mathcal{P})$ of the form

$$\{I_1, I_2, \cdots, I_k\} \to \{I_1, I_2, \cdots, J_k\}$$

  with I_k $\prec$-minimal in T_1 and $J_k \subseteq I_k$, then $F(e)$ exhibits $F(T_2)$ as the $\mathfrak{S}(J_k)$-localization of $F(T_1)$;
- if $e : T_1 \to T_2$ is an edge of $\mathbb{P}^m(\mathcal{P})$ of the form

$$\{I_1, I_2, \cdots, I_k\} \to \{I_1, I_2, \cdots, I_k, I_{k+1}\}$$

  with I_{k+1} $\prec$-minimal, then $F(e)$ exhibits $F(T_2)$ as the $\mathfrak{S}(I_{k+1})$-localization of $F(T_1)$.

Proposition 3.26. If $\mathcal{P}$ has cardinality at most m, then the functor

$$e_{\mathcal{P}} : \mathbf{C}_m^{\mathfrak{S}} \to \mathbf{C}$$

given by evaluation at $\{\mathcal{P}\}$ is an equivalence of categories.

Proof. We'll prove this by induction on m. If $m = 1$, there's nothing to do. If $m = 2$, then $\mathcal{P} \cong \Delta^1$ and we'll label its elements 0 and 1, with $0 > 1$ (this is unfortunately necessitated by our conventions). Then $\mathbf{C}_m^{\mathfrak{S}}$ is the category of squares of the form

$$\begin{array}{ccc} E & \rightarrowtail & E_0 \\ \downarrow & & \downarrow \\ E_1 & \longrightarrow & E_{10} \end{array}$$

in which $E_0 \in \mathfrak{S}(0)$, $E_1, E_{10} \in \mathfrak{S}(1)$ and the tailed arrows are localizations. By the stratification axioms, all such squares are cartesian. Then the fact that $e_{\Delta^1} : \mathbf{C}_m^{\mathfrak{S}} \to \mathbf{C}$ is an equivalence is discussed, in almost exactly these terms, in the proof of [Lur12, Proposition A.8.11].

In general, let $x \in \mathcal{P}$ be the unique element of $\mathcal{P} \backslash \mathcal{P}_{\leq n-1}$; then x is a maximal element. For convenience, we'll write $\mathcal{Q}$ for $\mathcal{P}_{\leq n-1}$. Observe that we have an isomorphism of posets

$$h : \Delta^1 \times ((\mathbb{P}^m(\mathcal{Q}))^{\triangleleft}) \to \mathbb{P}^m(\mathcal{P})$$

given by

$$\begin{aligned} h(0, c) &= \{\mathcal{P}\}, \\ h(1, c) &= \{\{x\}\}, \\ h(0, T) &= T, \\ h(1, T) &= \{\{x\}\} \cup T, \end{aligned}$$

where c is the cone point.

Now $\mathbf{C}$ admits a stratification $\mathfrak{S}'$ along Δ^1 wherein

$$\mathfrak{S}'(1) = \mathfrak{S}(\{x\}),\ \mathfrak{S}'(0) = \mathfrak{S}(\mathcal{Q}),$$

so that

$$\phi_{\Delta^1} : \mathbf{C}_m^{\mathfrak{S}'} \to \mathbf{C}$$

is an equivalence. On the other hand, $\mathfrak{S}(\mathcal{Q})$ obviously inherits a stratification $\mathfrak{S}''$ along $\mathcal{Q}$, and the functor

$$\phi_{\mathcal{Q}} : \mathfrak{S}(\mathcal{Q})_m^{\mathfrak{S}''} \to \mathfrak{S}(\mathcal{Q})$$

is an equivalence.

Here's what we deduce by combining these two equivalences. Let

$$\mathcal{K} = \mathbb{P}^m(\Delta^1) \amalg_{\Delta^1} (\mathbb{P}^m(\mathcal{Q}) \times \Delta^1)$$

where we've glued the edge $\{0\} \to \{0,1\}$ of $\mathbb{P}^m(\Delta^1)$ to the edge $\{\mathcal{Q}\} \times \Delta^1$ of $\mathbb{P}^m(\mathcal{Q}) \times \Delta^1$. Let $\overline{\mathbf{C}}$ be the full subcategory $\mathrm{Fun}(\mathcal{K}, \mathbf{C})$ spanned by those F for which

$$F|_{\mathbb{P}^m(\Delta^1)} \in \mathbf{C}_m^{\mathfrak{S}'}$$

and

$$F|_{\mathbb{P}^m(\mathcal{Q}) \times \{0\}}, F|_{\mathbb{P}^m(\mathcal{Q}) \times \{1\}} \in \mathfrak{S}(\mathcal{Q})_m^{\mathfrak{S}''}.$$

Then evaluation on $\{\Delta^1\} \in \mathbb{P}^m(\Delta^1)$ induces an equivalence of categories

$$e_{\Delta^1} : \overline{\mathbf{C}} \xrightarrow{\sim} \mathbf{C}.$$

But

$$\mathbb{P}^m(\Delta^1) \cong \Delta^1 \times \Delta^1,$$

and so

$$\mathcal{K} \cong (\Delta^1 \amalg_{\{1\}} \mathbb{P}^m(\mathcal{Q})) \times \Delta^1.$$

For any simplicial set S, the inclusion

$$\Delta^1 \amalg_{\{1\}} S \hookrightarrow S^{\triangleleft}$$

is inner anodyne, and so we get an inner anodyne composite

$$\mathcal{K} \hookrightarrow \Delta^1 \times ((\mathbb{P}^m(\mathcal{Q}))^{\triangleleft}) \xrightarrow{h} \mathbb{P}^m(\mathcal{P}),$$

giving an equivalence of categories $\mathrm{Fun}(\mathbb{P}^m(\mathcal{P}), \mathbf{C}) \simeq \mathrm{Fun}(\mathcal{K}, \mathbf{C})$, which restricts to an equivalence of categories $\mathbf{C}_m^{\mathfrak{S}} \to \overline{\mathbf{C}}$. Composing with e_{Δ^1} completes the proof. □

Proposition 3.27. For any $\mathcal{P}$ and any $\mathbf{C}$ stratified along $\mathcal{P}$, the restriction functor

$$r_m : \mathbf{C}_m^{\mathfrak{S}} \to \mathbf{C}_{m-1}^{\mathfrak{S}}$$

is an equivalence.

Proof. Let

$$\kappa_m : \mathbf{C}_{m-1}^{\mathfrak{S}} \to \mathrm{Fun}(\mathbb{P}^m(\mathcal{P}), \mathbf{C})$$

be the right Kan extension functor. We claim that $\mathbf{C}_m^{\mathfrak{S}}$ is equal to the essential image of κ_m.

Indeed, let q be the unique element of $\mathcal{P}_{\leq m} \setminus \mathcal{P}_{\leq m-1}$. Suppose

$$T \in \mathbb{P}^m(\mathcal{P}) \setminus \mathbb{P}^{m-1}(\mathcal{P}).$$

Then T is of the form

$$\{\{p_1\}, \cdots, \{p_k\}, \mathcal{P}^{\leq m}\}.$$

Let $\alpha : \Lambda_2^2 \to \mathbb{P}^{m-1}(\mathcal{P})$ be the functor with

$$\begin{aligned}
\alpha_T(0) &= \{\{p_1\}, \cdots, \{p_k\}, \{q\}\}, \\
\alpha_T(1) &= \{\{p_1\}, \cdots, \{p_k\}, \mathcal{P}_{\leq m-1}\}, \\
\alpha_T(2) &= \{\{p_1\}, \cdots, \{p_k\}, \{q\}, \mathcal{P}_{\leq m-1}\}.
\end{aligned}$$

Then α is coinitial in $\mathbb{P}^{m-1}(\mathcal{P})_{T/}$. Moreover, $F : \mathbb{P}^m(\mathcal{P}) \to \mathbf{C}$ is an object of $\mathbf{C}_m^{\mathfrak{S}}$ if and only if

- $F|_{\mathbb{P}^{m-1}(\mathcal{P})} \in \mathbf{C}_{m-1}^{\mathfrak{S}}$, and
- for each $T \in \mathbb{P}^m(\mathcal{P}) \setminus \mathbb{P}^{m-1}(\mathcal{P})$, $F(T) \in \mathfrak{S}(\mathcal{P}_{\leq m})$ and the maps

  $$F(T) \to F(\alpha_T(0)), F(T) \to \mathcal{F}(\alpha_T(1))$$

  are localizations.

But by the stratification axiom, the latter condition is equivalent to the condition that the square

$$\begin{array}{ccc} F(T) & \longrightarrow & F(\alpha_T(0)) \\ \downarrow & & \downarrow \\ F(\alpha_T(1)) & \longrightarrow & F(\alpha_T(2)) \end{array}$$

be a pullback. This completes the proof. □

If $n = |\mathcal{P}|$, we now have equivalences of categories $\mathbf{C}_n^{\mathfrak{S}} \xrightarrow{\sim} \mathbf{C}$ (Proposition 3.26) and $\mathbf{C}_n^{\mathfrak{S}} \xrightarrow{\sim} \mathbf{C}_1^{\mathfrak{S}} \cong \mathbf{C}^{\mathfrak{S}}$ (inductively, using Proposition 3.27). This consitutes a proof of Theorem 3.21.

Example 3.28. When $\mathbf{C}$ is the category $\mathbf{Sp}^G$ for a finite abelian group G, we recover the statement of [AK13, Theorem 3], though in substantially different language.

Example 3.29. Suppose p is a prime and $\mathcal{M} = \mathcal{O}_{C_p}$, so that $\mathcal{P} = \Delta^1$. Then Theorem 3.21 states, after unwinding the definition, that an object E of of $\mathbf{Mack}(\mathcal{M}) \simeq \mathbf{Sp}^{C_p}$ is given by the following data:

- A spectrum with C_p-action
$$E_1 \in \mathfrak{S}_{\mathcal{M}}(\{\{1\}\}) \simeq \mathrm{Fun}(BC_p, \mathbf{Sp}),$$
the underlying spectrum of E;
- a spectrum
$$E_0 \in \mathfrak{S}_{\mathcal{M}}(\{\{0\}\}) \simeq \mathbf{Sp},$$
the C_p-geometric fixed point spectrum of E;
- and a map
$$E_0 \to \mathcal{L}_{\{0\}} E_1 \simeq E_1^{tC_p}$$
where $(-)^{tG}$ is the Tate spectrum, defined by the cofiber sequence
$$(-)_{hG} \to (-)^{hG} \to (-)^{tG}.$$

The epiorbital category $\mathcal{F}_s^{\leq 2}$ is visibly equivalent to $\mathcal{O}_{C_2}$, so an object

$$F \in \mathbf{Mack}(\mathcal{F}_s^{\leq 2}) \simeq \mathrm{Fun}^{2-exc}(\mathbf{Sp}, \mathbf{Sp})$$

is given by the same data as an object of $\mathbf{Sp}^{C_2}$, but in this case, E_1 and E_0 are interpreted as the second and first derivatives of F, respectively. This classification of 2-excisive functors was first carried out in [AC15, §5].

We'll close this section by saying a few words about what happens for infinite posets. Let $\mathcal{P}$ be an infinite poset equipped with a system of finite subposets

$$\emptyset = \mathcal{P}_{\leq 0} \subseteq \mathcal{P}_{\leq 1} \subseteq \cdots \subseteq \mathcal{P}_{\leq n} \subseteq \cdots \subseteq \mathcal{P}$$

which is a threading in the sense that for each i, $\mathcal{P}_{\leq i}$ is downwardly closed and has cardinality i, and

$$\bigcup_n \mathcal{P}_{\leq n} = \mathcal{P}.$$

Definition 3.30. Suppose

$$0 = \mathbf{C}_0 \subseteq \mathbf{C}_1 \subseteq \cdots \subseteq \mathbf{C}_n \subseteq \cdots$$

is a sequence of stable ∞-categories such that $\mathbf{C}_{n-1}$ is a reflective stable subcategory of $\mathbf{C}_n$ for all n. Suppose we have, for each n, a stratification $\mathfrak{S}_n$ of $\mathbf{C}_n$ along $\mathcal{P}_{\leq n}$, and that all of these are compatible in the sense that

$$\mathbf{C}_{n-1} = \mathfrak{S}_n(\mathcal{P}_{\leq n-1})$$

and $\mathfrak{S}_{n-1}$ is the induced stratification. Let

$$\mathbf{C}_\infty := \lim_n \mathbf{C}_n$$

be the limit over the localization maps. We call this data a *pro-stratification* of $\mathbf{C}_\infty$ along $\mathcal{P}$.

Then it follows from the proof of Theorem 3.21 that the diagram

$$\begin{tikzcd} \mathbf{C}_n \arrow[d, "\mathbf{L}_{\mathcal{P}_{\leq n-1}}"'] & (\mathbf{C}_n)_n^{\mathfrak{S}_n} \arrow[l, "\sim"', "e_{\mathcal{P}_{\leq n}}"] \arrow[r, "\sim"] \arrow[d] & \mathbf{C}_n^{\mathfrak{S}_n} \arrow[d] \\ \mathbf{C}_{n-1} & (\mathbf{C}_{n-1})_{n-1}^{\mathfrak{S}_{n-1}} \arrow[l, "\sim"', "e_{\mathcal{P}_{\leq n-1}}"] \arrow[r, "\sim"] & \mathbf{C}_{n-1}^{\mathfrak{S}_{n-1}} \end{tikzcd}$$

commutes up to homotopy for every n. Taking the limit as $n \to \infty$ gives an equivalence

$$\mathbf{C}_\infty \to \lim_n \mathbf{C}_n^{\mathfrak{S}_n} =: \mathbf{C}_\infty^{\mathfrak{S}}.$$

The limit $\mathbf{C}_\infty^{\mathfrak{S}}$ can be described explicitly as follows. Let

$$\mathbb{P}^\infty = \operatorname*{colim}_n \mathbb{P}(\mathcal{P}_n).$$

and

$$\mathbf{C}^\infty := \operatorname*{colim}_n \mathbf{C}_n$$

(which differs from $\mathbf{C}_\infty$ in that we have taken the colimit over the inclusions rather than the limit over the localizations). Then $\mathbf{C}_\infty^{\mathfrak{S}}$ is the full subcategory of $\mathrm{Fun}(\mathbb{P}^\infty, \mathbf{C}^\infty)$ spanned by those functors F for which

$$F|_{\mathbb{P}(\mathcal{P}_n)} \in \mathbf{C}_n^{\mathfrak{S}_n}.$$

Thus we have a description of $\mathbf{C}_\infty$ in terms of (infinite) diagrams of maximally local objects.

Example 3.31. With $\mathcal{P}$ as above, let $\mathbf{C}$ be a symmetric monoidal presentable stable ∞-category and let $(K_p)_{p\in\mathcal{P}}$ be a collection of objects of $\mathbf{C}$ such that any K_p-local object is K_q-acyclic unless $p \geq q$. Then letting

$$\mathbf{C}_n = \mathbf{L}_{\bigvee_{p\in\mathcal{P}_{\leq n}} K_p}\mathbf{C}$$

gives a pro-stratification of

$$\mathbf{C}_\infty = \mathbf{L}_{\bigvee_{p\in\mathcal{P}} K_p}\mathbf{C}$$

along $\mathcal{P}$. In the case where $\mathcal{P} = \mathbb{N}^{\mathrm{op}}$ and K_n is the Morava K-theory $K(n)$, we have expressed the category of harmonic spectra in terms of diagrams of $K(n)$-local spectra.

Example 3.32. Let

$$\emptyset = \mathcal{M}_0 \subseteq \mathcal{M}_1 \subseteq \cdots \subseteq \mathcal{M}_n \subseteq \cdots \subseteq \mathcal{M} = \operatorname*{colim}_n \mathcal{M}_n$$

be a sequence of inclusions of EOCs giving rise to the threading

$$\mathcal{P}_0 \subseteq \mathcal{P}_1 \subseteq \cdots \subseteq \mathcal{P}_n \subseteq \cdots$$

on posets of isomorphism classes. Then $\mathcal{M}^{\amalg}$ is disjunctive and we may speak of the category $\mathbf{Mack}(\mathcal{M}, \mathbf{C})$ of additive functors from $A^{eff}(\mathcal{M}^{\amalg})$ into some stable target category $\mathbf{C}$. Letting

$$\mathbf{C}_n = \mathbf{Mack}(\mathcal{M}_n, \mathbf{C})$$

gives a pro-stratification of $\mathbf{Mack}(\mathcal{M}, \mathbf{C})$ along $\mathcal{P}$.

Example 3.32 has a couple of interesting special cases:

Example 3.33. Let $\mathcal{M}_n = \mathcal{F}_s^{\leq n}$. Then $\mathcal{M}$ is the category $\mathcal{F}_s$ of all finite sets and surjective maps, and $\mathbf{Mack}(\mathcal{M}, \mathbf{C})$ is equivalent to the category of functors $F : \mathbf{Sp} \to \mathbf{C}$ which are *weakly analytic* in the sense that

$$F \simeq \lim_n P_n F.$$

Example 3.34. Let G be a profinite group and let $\mathcal{M}$ be the category of finite G-orbits. Then any threading of the poset $\mathcal{P}$ of isomorphism classes in $\mathcal{M}$ gives a pro-stratification of $\mathbf{Mack}(\mathcal{M}, \mathbf{C})$, which should be thought of a kind of category of genuine G-objects in which only the fixed points under cofinite subgroups are salient.

It's worth noting that given a cofinal system of finite quotients $(H_m)_{m\in\mathbb{N}}$ of G, we could choose our threading so that for each m, there is some n_m such that

$$\mathcal{M}_{n_m} = \mathcal{O}_{H_m}.$$

Thus

$$\mathbf{Mack}(\mathcal{M}, \mathbf{C}) \simeq \lim_{G\twoheadrightarrow H, H \text{ finite}} \mathbf{Mack}(\mathcal{O}_H, \mathbf{C}).$$

4 $K(n)$-local theory

In this brief section, we'll see that symmetry properties which emerge when one works locally with respect to the Morava K-theories $K(n)$ cause large chunks of this theory to collapse. We'll reprove a result of Kuhn on the $K(n)$-local splitting of Taylor towers, and give a new tom Dieck-like splitting result for $K(n)$-local G-spectra.

The following "chromatic blueshift" theorem is a consequence of the results of [GS96] and [HS96]; it appears in roughly this form in [HL13], and as we shall see, [Kuh04] is also highly relevant.

Theorem 4.1. Let G be a finite group and let E be a $K(n)$-local spectrum with G-action. Then the transfer map

$$N : E_{hG} \to E^{hG}$$

is a $K(n)$-local equivalence. Thus the Tate spectrum E^{tG} is $K(n)$-acyclic.

Theorem 4.2. If $\mathcal{M}$ is a epiorbital category and $\mathbf{C}$ is a stable ∞-category such that all Tate spectra are zero - for instance, the category of $K(n)$-local spectra - then the comonad DR of Theorem 2.38 is the identity comonad, and so the Taylor sequence functor

$$D : \mathbf{Mack}(\mathcal{M}, \mathbf{C}) \to \mathrm{Fun}(\mathcal{M}^{\sim}, \mathbf{C})$$

is an equivalence.

Having got this far, the proof is fairly simple.

Proof. Let X be an object of $\mathcal{M}$ and let i_X once again denote the full inclusion $A^{eff}(\mathcal{G}_X) \hookrightarrow A^{eff}(\mathcal{M}_{\leq X})$, where $\mathcal{G}_X$ is the full subcategory of $\mathcal{M}$ spanned by X. Let $E \in \mathrm{Fun}(\mathcal{G}_X, \mathbf{C})$. Then for any $Y \in \mathcal{M}_{\leq X}$, the natural map

$$(i_X)_!(E)(Y) \to (i_X)_*(E)(Y)$$

takes the form

$$\bigoplus_{f \in \mathrm{Map}_{\mathcal{M}}(X,Y)/\text{isomorphism}} E_{h\mathrm{Aut}_f(X)} \to \bigoplus_{f \in \mathrm{Map}_{\mathcal{M}}(X,Y)/\text{isomorphism}} E^{h\mathrm{Aut}_f(X)}$$

and is thus an equivalence, by our hypothesis. We deduce that for each $X \in \mathcal{M}$,

$$L^X \simeq R^X,$$

and so

$$L \simeq R.$$

But $DL \simeq \mathrm{id}$ (Proposition 2.37) and so $DR \simeq \mathrm{id}$. This completes the proof. $\square$

Corollary 4.3. Any $K(n)$-local G-spectrum E (by which we mean a Mackey functor valued in the $K(n)$-local category) satisfies a very strong tom Dieck splitting property: we have an equivalence

$$E \simeq \bigvee_{H \leq G/\text{conjugacy}} L^{G/H} E^{\Phi H}.$$

In particular, for each $H \leq G$, we have a canonical decomposition

$$E^H \simeq \bigvee_{(K \leq H)/\text{conjugacy in } G} \left((E^{\Phi K})_{hW(H,K)}\right)$$

where $W(H, K)$ is the relative Weyl group, defined as

$$W(H, K) := (N_G(K) \cap H)/K.$$

Corollary 4.4 (Kuhn)**.** Let $F : \mathbf{Sp} \to \mathbf{Sp}$ be an m-excisive functor taking values in $K(n)$-local spectra. Then the Taylor tower for F splits: we have an equivalence

$$F(X) \simeq \bigvee_{i=0}^{m} \mathbb{D}_i F(X).$$

A The free semiadditive ∞-category on a group

This appendix is devoted to proving Theorem 2.27, which we restate here (with slightly different notation) for convenience:

Theorem A.1. Let G be an (ordinary) groupoid. Then $A^{eff}(G^{\amalg})$ is the free semiadditive ∞-category on G: for any semiadditive ∞-category $\mathbf{C}$, the natural inclusion induces an equivalence of categories

$$\mathrm{Fun}^{\oplus}(A^{eff}(G^{\amalg}), \mathbf{C}) \to \mathrm{Fun}(G, \mathbf{C}).$$

First, we note that we may assume G is connected. Indeed, having proved this, the general case will follow from the fact that if $(\mathcal{M}_i)_{i \in I}$ is an I-indexed family of orbital categories, then

$$A^{eff}\left(\left(\coprod_I \mathcal{M}_i\right)^{\amalg}\right) \simeq \bigoplus_I A^{eff}(\mathcal{M}_i^{\amalg}).$$

We will further assume that our connected groupoid has only one object, and denote the corresponding group, too, by G.

Now let's get some notation out of the way. Let $\mathcal{F}_*$ be the category of finite pointed sets. If $S \in \mathcal{F}_*$, denote by S^o the finite set $S \setminus \{*\}$. If $s \in S^o$, denote by $\chi_s : S \to \{s\}_+$ the characteristic map at s:

$$\chi_s(t) = \begin{cases} s & t = s \\ * & \text{otherwise.} \end{cases}$$

Definition A.2. [Lur12, Remark 2.4.2.2] Let $\mathbf{C}$ be an ∞-category which admits finite products. Recall that by definition, the category $\mathbf{CMon}(\mathbf{C})$ of *commutative monoids* in $\mathbf{C}$ is the full subcategory of $\mathrm{Fun}(\mathcal{F}_*, \mathbf{C})$ spanned by those functors F satisfying the Segal condition: for each $S \in \mathcal{F}_*$, the edges $F(S) \to F(\{s\}_+)$ determine an equivalence

$$F(S) \simeq \prod_{s \in S^o} F(\{s\}_+).$$

We'll abbreviate $\mathbf{CMon}(\mathbf{Top})$ to $\mathbf{CMon}$.

Now let's begin the proof. First we note that $G^{\amalg}$ is equivalent to the category $\mathcal{F}r^{\mathcal{G}}$ of finite sets with *free* G-action.

Definition A.3. Let $\mathcal{L}(G)$ be the Lawvere theory of commutative monoids with G-action: the full subcategory of $\mathrm{Fun}(G, \mathbf{CMon})$, which is equivalent to $\mathbf{CMon}(\mathrm{Fun}(G, \mathbf{Top}))$, spanned by the the essential image of $\mathcal{F} \subseteq \mathbf{Top}$ under the left adjoint of the forgetful functor $\mathrm{Fun}(G, \mathbf{CMon}) \to \mathbf{Top}$.

Theorem A.4. There is an equivalence of categories between $A^{eff}(\mathcal{F}r^G)$ and $\mathcal{L}(G)$.

Proof. First let's construct the functor. $\mathrm{Fun}(G, \mathbf{CMon})$ is a certain full subcategory of $\mathrm{Fun}(G \times \mathcal{F}_*, \mathbf{Top})$, so we can do this by constructing a functor

$$A^{eff}(\mathcal{F}r^G) \times G \times \mathcal{F}_* \to \mathbf{Top}$$

adjointing over, and checking it makes sense on objects.

We'll do the construction in two stages. First, note that we have a functor

$$A^{eff}(\mathcal{F}r^G) \times A^{eff}(\mathcal{F}) \to A^{eff}(\mathcal{F}r^G)$$

simply by taking objectwise products of staircase diagrams. We also have an inclusion $i : \mathcal{F}_* \to A^{eff}(\mathcal{F})$ as follows: an n-simplex of $\mathcal{F}_*$, given by a chain of pointed maps

$$X_0 \xrightarrow{f_1} X_1 \xrightarrow{f_2} \cdots \xrightarrow{f_n} X_n$$

maps to the staircase diagram $(A_{ij})_{0 \le i \le j \le n}$ with

$$\begin{cases} A_{ii} = X_i^o & i = j \\ A_{ij} = (f_j f_{j-1} \cdots f_{i+1})^{-1} X_j^o & i \neq j. \end{cases}$$

Functoriality is easily checked, as is the fact that all squares which ought to be pullbacks are pullbacks. Composing these two and multiplying by G, we get a map

$$\mu : A^{eff}(\mathcal{F}r^G) \times G \times \mathcal{F}_* \to A^{eff}(\mathcal{F}r^G) \times G.$$

Next, we'll define a functor $A^{eff}(\mathcal{F}r^G) \times G \to \mathbf{Top}$ by defining a left fibration

$$\kappa : A^{eff}(\mathcal{F}r^G)_+ \ltimes G \to A^{eff}(\mathcal{F}r^G) \times G.$$

Here $A^{eff}(\mathcal{F}r^G)_+ \ltimes G$ is itself the total space of a cocartesian fibration over G. A vertex of $A^{eff}(\mathcal{F}r^G)_+ \ltimes G$ is a free G-set U together with a finite set S and a map of sets $S \to U$. An edge of $A^{eff}(\mathcal{F}r^G)_+ \ltimes G$ with source $a_1 : S_1 \to U_1$ and target $a_2 : S_2 \to U_2$ is an element $g \in G$ together with a diagram

$$\begin{tikzcd} S_1 \arrow[d, "g\circ a_1"] & S_2 \arrow[l] \arrow[d] \arrow[dd, bend left, "a_2"] \arrow[dl, phantom, "\lrcorner"] \\ U_1 & W \arrow[l] \arrow[d] \\ & U_2 \end{tikzcd}$$

with higher simplices defined analogously. We define κ to be the map that forgets S. To prove that κ is a left fibration, define $A^{eff}(\mathcal{F}r^G)_+$ to be the fiber of $A^{eff}(\mathcal{F}r^G)_+ \ltimes G$ over the vertex of G. κ restricts to a map

$$A^{eff}(\mathcal{F}r^G)_+ \to A^{eff}(\mathcal{F}r^G)$$

which is actually isomorphic to the target map

$$t : A^{eff}(\mathcal{F}r^G)_{G/} \to A^{eff}(\mathcal{F}r^G)$$

which is definitely a left fibration. Together with the fact that the preimage under κ of an edge of G is an equivalence, this implies that κ itself is a left fibration.

Let K be a functor $A^{eff}(\mathcal{F}r^G) \times G \to \mathbf{Top}$ that classifies κ. We now have a well-defined functor

$$\sigma : A^{eff}(\mathcal{F}r^G) \to \mathrm{Fun}(G \times \mathcal{F}_*, \mathbf{Top})$$

defined by composing μ with K and then taking adjoints. For each free finite G-set U, we must show that the functor

$$\mathcal{F}_* \times \{U\} \xrightarrow{\mu} A^{eff}(\mathcal{F}r^G) \to \mathrm{Fun}(G, \mathbf{Top})$$

is a commutative monoid. Unwinding the definitions shows that this is a consequence of the fact that K preserves products. Moreover, one identifies $\sigma(U)$ with

$$(\Sigma)^{\times U},$$

where $\Sigma = \coprod_{n \geq 0} \Sigma_n$ and G acts by permutation on the factors. This is equivalent to the free commutative monoid in $\mathrm{Fun}(G, \mathbf{Top})$ on the set U/G. So σ factors through a functor

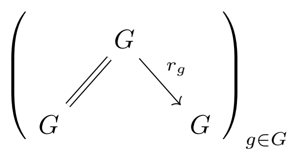
$$\alpha : A^{eff}(\mathcal{F}r^G) \to \mathcal{L}(G).$$

From here, showing that α is an equivalence is the easy part. Essential surjectivity is obvious. For full faithfulness, it suffices to show that α induces an equivalence

$$\alpha_0 : \mathrm{Map}_{A^{eff}(\mathcal{F}r^G)}(G, G) \to \mathrm{Map}_{\mathcal{L}(G)}(\Sigma^{\times G}, \Sigma^{\times G})$$

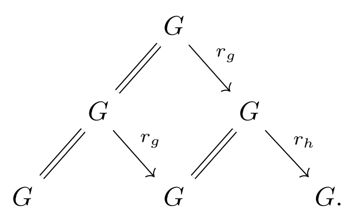
since all of the other relevant maps are products of some copies of this one.

Since G is a commutative monoid in $A^{eff}(\mathcal{F}r^G)$ and $\Sigma^{\times G}$ is a commutative monoid in $\mathcal{L}(G)$, α_0 underlies a map of commutative monoids, both of which are easily seen to be equivalent as commutative monoids to $\Sigma^{\times G}$. Thus it's enough to check that α_0 takes a set of free generators to a set of free generators. On the left, we may take this set to be



where r_g is right multiplication by g. On the other hand, we may take our set of generators on the right to be those automorphisms of $\Sigma^{\times G}$ induced by right multiplication by elements of g. Tracing through the definitions a final time, we see that α_0 maps the one set of generators to the other. This completes the proof. ☐

We have the functor $G \to A^{eff}(\mathcal{F}r^G)$ that takes, for example, a 2-simplex (g, h) to the diagram

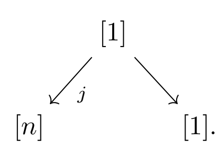


We have the composite

$$i_G : G \times \mathcal{F}_* \to A^{eff}(\mathcal{F}r^G) \times A^{eff}(\mathcal{F}) \to A^{eff}(\mathcal{F}r^G).$$

Proposition A.5. i_G is the universal commutative monoid with G-action, which is to say the initial functor satisfying the Segal condition from $G \times \mathcal{F}_*$ to a category with finite products.

Proof. First we must show that i_G is indeed a commutative monoid. G doesn't make any difference here; we just need to show that $i : \mathcal{F}_* \to A^{eff}(\mathcal{F})$ satisfies the Segal condition. This follows from the fact that the image of the inert map $\chi_j : \langle n \rangle \to \langle 1 \rangle$ is the span



Now let $U(G)$ be the universal category supporting a commutative monoid with G-action. Since $U(G)$ is the initial category under $G \times \mathcal{F}_*$ that takes certain diagrams to limit diagrams, Proposition 5.3.6.2 of [Lur09] gives a prescription for building it as the opposite of a full subcategory of a certain localization $S^{-1}\mathbf{Psh}((G\times\mathcal{F}_*)^{\mathrm{op}})$ of the presheaf category $\mathbf{Psh}((G\times\mathcal{F}_*)^{\mathrm{op}})$. Since we're in this business, let's let $Y : (G\times\mathcal{F}_*)^{\mathrm{op}} \to \mathbf{Psh}((G\times\mathcal{F}_*)^{\mathrm{op}})$ denote the Yoneda embedding.

In this case, the localization S is generated by the morphisms

$$\coprod_{\langle n\rangle^o} Y(\langle 1\rangle) \to Y(\langle n\rangle)$$

given by precomposition with the inert maps, and so localization is "Segalification" and the local objects are exactly the commutative monoid spaces with G-action. Thus $U(G)^{\mathrm{op}}$ is the full subcategory of $\mathrm{Fun}(\mathcal{F}_*\times G,\mathbf{Top})$ spanned by the Segalifications of

$$\coprod_{\langle n\rangle^o} Y(\langle 1\rangle)$$

as n varies. But $Y(\langle 1\rangle)$ is, by definition, left Kan extended along the inclusion

$$\langle 1\rangle : * \to \mathcal{F}_*\times G$$

and so its Segalification is the free commutative monoid with G-action on one generator. Since Segalification preserves coproducts, the other objects follow.

Now we've given an equivalence between $U(G)^{\mathrm{op}}$ and $\mathcal{L}(G)$, and therefore $A^{eff}(\mathcal{F}r^G)$. We know that this category is canonically self-opposite, so we might as well forget the op on $U(G)$. Let's show that this equivalence comes from i_G.

Since $A^{eff}(\mathcal{F}r^G)$ is semiadditive, specifying a commutative monoid with G-action $BG\times\mathcal{F}_*\to A^{eff}(\mathcal{F}r^G)$ is equivalent to specifying it on $G\times\langle 1\rangle$ (see Corollary 2.4.3.10 of [Lur12]). Both i_G and the universal commutative monoid in $U(G)$ take $G\times\langle 1\rangle$ to the G-set G with its right action on itself. This completes the proof. ◻

Corollary A.6. Let $\mathbf{C}$ be an ∞-category with finite products. Then pullback along i_G gives an equivalence

$$\mathrm{Fun}^{\times}(A^{eff}(\mathcal{F}r^G),\mathbf{C}) \to \mathbf{CMon}(\mathrm{Fun}(G,\mathbf{C})).$$

Proof. This is just a restatement of A.5. ◻

We deduce Theorem 2.27 as the special case of A.6 where $\mathbf{C}$ is semiadditive.

B The proof of Lemma 2.36

Lemma B.1. Let $\mathbf{C}$ be an ∞-category, $z : \mathbf{D}\to\mathbf{C}$ the inclusion of a full subcategory and $X\in\mathbf{C}$ an object. Let $\star$ denote the join of simplicial sets, and let

$$\begin{aligned}i_0 : \Delta^0 &\to \Delta^0 \star (\Delta^n \times \Delta^1)\\ i_1 : \Delta^n \times \{0\} &\to \Delta^0 \star (\Delta^n \times \Delta^1)\\ i_2 : \Delta^n \times \{1\} &\to \Delta^0 \star (\Delta^n \times \Delta^1)\end{aligned}$$

be the natural inclusions. We define a simplicial set $\mathbf{C}_{X/\mathbf{D}/}$ whose n-simplices are maps $\alpha : \Delta^0 \star (\Delta^n \times \Delta^1) \to \mathbf{C}$ with

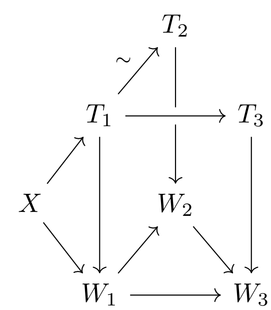
$$\alpha \circ i_0 = X, \quad \alpha \circ i_1 \in \mathrm{Fun}(\Delta^n, \mathbf{D}).$$

Then the map $p_2 : \mathbf{C}_{X/\mathbf{D}/} \to \mathbf{C}$ coming from precomposition with i_2 is cocartesian, and its cocartesian edges are those α for which the image of $\alpha \circ i_1$ is an equivalence. Moreover, the inclusion

$$\lambda : \mathbf{C}_{X/} \times_{\mathbf{C}} \mathbf{D} \hookrightarrow \mathbf{C}_{X/\mathbf{D}/}$$

formed by precomposition with the collapse map $\Delta^0 \star (\Delta^n \times \Delta^1) \to \Delta^0 \star \Delta^n$ is coinitial, and therefore left anodyne [Lur09, Proposition 4.1.1.3].

Proof. First we show that any edge α for which $\alpha \circ i_1$ is an equivalence is cocartesian. This is the claim that any commutative diagram of the form

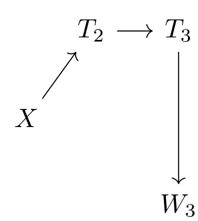


with $T_1 \to T_2$ an equivalence can be completed to a diagram from $\Delta^0 \star (\Delta^2 \times \Delta^1)$, which is clear by inspection. Since there are plenty of these edges, p_2 is cocartesian.

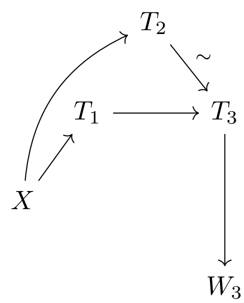
Now we tackle the coinitiality claim. In fact, we'll show that λ admits a right adjoint, which suffices. Let $\Lambda \to \Delta^1$ be the cocartesian fibration classified by λ; an n-simplex of Λ is a map $\tau : \Delta^n \to \Delta^1$ together with a map

$$\alpha : \left(\Delta^0 \star \left\{(i, j) \in \Delta^n \times \Delta^1 \,|\, j = 0 \text{ or } i \in \tau^{-1}(1)\right\}\right) \to \mathbf{C}$$

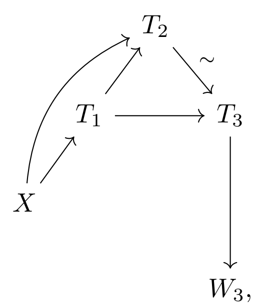
We wish to show that α is also cartesian. In fact, we claim that an edge



of Λ over the nondegenerate edge of Δ^1 is cartesian if $T_2 \to T_3$ is an equivalence. This is the claim that any commuting diagram of the form



can be extended to a commuting diagram of the form



which, again, is clear. □

We list some formal consequences of Lemma B.1.

Corollary B.2. Let $\mathbf{C}^{\mathbf{Top}}_{X/\mathbf{D}/}$ be a fibrant replacement for $\mathbf{C}_{X/\mathbf{D}/}$ in the covariant model structure over $\mathbf{C}$, so that $\mathbf{C}^{\mathbf{Top}}_{X/\mathbf{D}/} \to \mathbf{C}$ is a left fibration and for each object $W \in \mathbf{C}$, the map

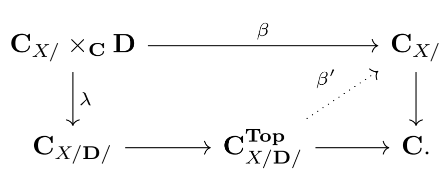
$$(\mathbf{C}^{\mathbf{Top}}_{X/\mathbf{D}/})_W \to (\mathbf{C}_{X/\mathbf{D}/})_W$$

is a Kan-Quillen weak equivalence. Then the functor classified by $\mathbf{C}^{\mathbf{Top}}_{X/\mathbf{D}/}$ is equivalent to the restriction and left Kan extension $z_! z^* \mathrm{Map}(X, -)$ of the functor corepresented by X.

Now let $\beta : \mathbf{C}_{X/\mathbf{D}/} \to \mathbf{C}_{X/}$ be given on n-simplices by precomposition with

$$i_0 \star i_2 : \Delta^0 \star \Delta^n \to \Delta^0 \star (\Delta^n \times \Delta^1).$$

Since $\mathbf{C}_{X/}$ is a left fibration, we have a commutative diagram



It follows that the counit map $c_X : z_! z^* \mathrm{Map}(X, -) \to \mathrm{Map}(X, -)$ is given, after unstraightening, by β'.

Lemma B.3. Let $W \in \mathbf{C}$ and let $f : X \to W$ be a morphism in $\mathbf{C}$. Then the homotopy fiber of

$$c_{X,W} : (z_! z^* \mathrm{Map}(X, -))_W \to \mathrm{Map}(X, W)$$

over f is given, up to weak equivalence, by the simplicial set $\mho_{W,f}$ whose n-simplices are maps $Z : \Delta^{n+2} \to \mathbf{C}$ such that

- $Z|_{\Delta^{\{0,n+2\}}} = f$, and
- for each i with $0 < i < n+2$, $Z(i) \in \mathbf{D}$.

Proof. We know that the Joyal model structure is self-enriched, by using [Lur09, Corollary 2.2.5.4] to deduce that the pushout-product of a trivial cofibration with a cofibration is a trivial cofibration, and it follows that if $K \to L$ is any cofibration of simplicial sets and $\mathbf{E}$ is a quasicategory, then $\mathrm{Fun}(L, \mathbf{E}) \to \mathrm{Fun}(K, \mathbf{E})$ is a categorical fibration. Since β is formed from such a fibration by pullback, β is also a categorical fibration.

The value of c_X on W is given, up to weak equivalence, by the map

$$\beta_W : (\mathbf{C}_{X/\mathbf{D}/})_W \to (\mathbf{C}_{X/})_W = \mathrm{Hom}^L(X, W).$$

Since the target of β_W is a Kan complex and β_W is a categorical fibration, it is a cocartesian fibration [Lur09, Proposition 3.3.18], and since a fibrant replacement for β_W in the covariant model structure over $\mathrm{Hom}^L(X, W)$ is automatically a Kan fibration, the fibers of β_W are its homotopy fibers.

By definition, the fiber $\beta_{W,f}$ over $f \in \mathrm{Hom}^L(X, W)$ is the simplicial set whose n-simplices are maps $Z' : (\Delta^0 \star (\Delta^n \times \Delta^1))/(\Delta^n \times \{1\}) \to \mathbf{C}$ such that

- $Z' \circ i_1 \subseteq \mathbf{D}$, and
- the $(n+1)$-simplex $Z' \circ (i_0 \star i_2)$ is the image of f under the rightmost degeneracy; that is, it is the totally degenerate n-simplex of $\mathbf{C}_{X/}$ at f.

In other words, an n-simplex of $\beta_{W,f}$ is a map

$$Z'' : \Delta^0 \star ((\Delta^n \times \Delta^1)/(\Delta^n \times \{1\}))$$

with $Z''(\Delta^n \times \{0\}) \in \mathbf{D}_n$ and $Z''(\Delta^0 \star ((\Delta^n \times \{1\})/(\Delta^n \times \{1\})) = f$. From here, the proof that $\beta_{W,f} \simeq \mho_{W,f}$ is a minor variant of the proof of [Lur09, Proposition 4.2.1.5]. ∎

We now immerse ourselves in the notation of Lemma 2.36, which we restate here for convenience.

Lemma B.4. Let $\mathcal{M}$ be an epiorbital category, $\mathcal{N}$ a downwardly closed subcategory of $\mathcal{M}$ and $\mathcal{T}$ its upwardly closed complement. Denote the restriction $A^{eff}(i_{\mathcal{T}})^*$ and the left Kan extension $A^{eff}(i_{\mathcal{T}})_!$ respectively by $\Pi^{\mathcal{T}}$ and $\Gamma^{\mathcal{T}}$, and similarly denote $A^{eff}(j_{\mathcal{N}})^*$ and $A^{eff}(j_{\mathcal{N}})_!$ by $\Xi^{\mathcal{N}}$ and $\Phi^{\mathcal{N}}$ respectively. Then there's a cofiber sequence of functors $\mathbf{Mack}(\mathcal{M}, \mathbf{CMon}) \to \mathbf{Mack}(\mathcal{M}, \mathbf{CMon})$

$$\Gamma^{\mathcal{T}}\Pi^{\mathcal{T}} \xrightarrow{\epsilon} \mathrm{Id} \xrightarrow{\eta} \Xi^{\mathcal{N}}\Phi^{\mathcal{N}},$$

where ϵ and η are the counit and unit of their respective adjunctions.

Proof. Since all of the functors in this sequence are colimit-preserving, it suffices to check that its value on each corepresentable Mackey functor is a cofiber sequence. Let $X \in A^{eff}(\mathcal{M})$ be an object and let $f : X \leftarrow Y \to W$ be a morphism in $A^{eff}(\mathcal{M})$. We'll analyze the fiber $\mho_{W,f}$ of Lemma B.3.

For $\mathbf{C}$ an ∞-category, let $\widetilde{\mathcal{O}}_{\mathbf{C}}$ be the twisted arrow category of $\mathbf{C}$ (see [Bar14, §2]) and let $\widetilde{\mathcal{O}}^{\mathbf{C}} := \widetilde{\mathcal{O}}_{\mathbf{C}}^{\mathrm{op}}$ be its opposite. Then an n-simplex of $\mho_{W,f}$ is by definition a functor

$$\varrho : \widetilde{\mathcal{O}}^{\Delta^{n+2}} \to \mathcal{M}^{\amalg}$$

such the span

$$\varrho(0,0) \leftarrow \varrho(0,n+2) \to \varrho(n+2,n+2)$$

coincides with f and $\varrho(i,i) \in \mathcal{T}^{\amalg}$ for all i with $0 < i < n+2$. By the upward closedness of $\mathcal{T}$, the latter condition implices that $\varrho(i,j) \in \mathcal{T}^{\amalg}$ for all $(i,j) \neq (0,0), (n+2,n+2)$, and in particular $\mho_{W,f}$ is empty unless $Y \in \mathcal{T}^{\amalg}$. We claim that if $Y \in \mathcal{T}^{\amalg}$, then $\mho_{W,f}$ is contractible. In fact, let $\Gamma_{W,f}$ be the subsimplicial set of $\mho_{W,f}$ whose n-simplices are those which factor through the morphism

$$\gamma : \widetilde{\mathcal{O}}^{\Delta^{n+2}} \to \widetilde{\mathcal{O}}^{\Delta^{n+2}} \qquad \gamma(i,j) = \begin{cases} (0,0) & \text{if } (i,j) = (0,0) \\ (n+2,n+2) & \text{if } (i,j) = (n+2,n+2) \\ (0,n+2) & \text{otherwise.} \end{cases}$$

If $Y \in \mathcal{T}^{\amalg}$, then clearly $\Gamma_{W,f} \cong *$, and we claim that $\Gamma_{W,f}$ is a simplicial deformation retract of $\mho_{W,f}$. We'll do this in two stages as follows. For each integer k, let $\gamma_k^L : \widetilde{\mathcal{O}}^{\Delta^{n+2}} \to \widetilde{\mathcal{O}}^{\Delta^{n+2}}$ be defined by

$$\gamma_k^L(i,j) = (\min(i-k,0), j)$$

and dually, define $\gamma_k^R : \widetilde{\mathcal{O}}^{\Delta^{n+2}} \to \widetilde{\mathcal{O}}^{\Delta^{n+2}}$ by

$$\gamma_k^R(i,j) = (i, \max(j+k, n+2)).$$

Let $\Gamma_{W,f}^L$ be the subsimplicial set of $\mho_{W,f}$ whose n-simplices factor through γ_{n+1}^L, and define $\Gamma_{W,f}^R$ similarly; we will show that each of $\Gamma_{W,f}^L$ and $\Gamma_{W,f}^R$ is a simplicial deformation retract of $\mho_{W,f}$, and since

$$\Gamma_{W,f} = \Gamma_{W,f}^L \cap \Gamma_{W,f}^R,$$

this will complete the proof of the claim. We will prove the result for $\Gamma^R_{W,f}$; the result for $\Gamma^L_{W,f}$ is, of course, entirely dual.

For each n, l with $0 \leq l \leq n+1$, let $\tau_{n,l} : \Delta^n \to \Delta^1$ be the unique map with

$$\tau_{n,l}^{-1}(0) = [0, \cdots, n-l],$$

where we interpret $[0, -1]$ as the empty interval. Then we define a map

$$\Theta : \mho_{W,f} \times \Delta^1 \to \mho_{W,f}$$

on n-simplices by

$$(\varrho, \tau_{n,l}) \mapsto \varrho \circ \gamma_l^R.$$

Then Θ_1 is a retraction onto $\Gamma^R_{W,f}$, so we have the required simplicial homotopy.

What we have proved so far is that

$$\epsilon_{c_X} : \Gamma^{\mathcal{T}} \Pi^{\mathcal{T}} c_X \to c_X,$$

after evaluation on an object W, is homotopic to the inclusion of the connected components of $\mathrm{Map}(X, W)$ comprising those maps $f : X \leftarrow Y \to W$ with $Y \in A^{eff}(\mathcal{T})$. What's left is easy: $\eta_{c_X}(W)$ is the natural map

$$\mathrm{Map}_{A^{eff}(\mathcal{M})}(X, W) \to \mathrm{Map}_{A^{eff}(\mathcal{N})}(j(X), j(W)),$$

which is just the projection away from the image of $\epsilon_{c_X}(W)$. This concludes the proof of Lemma 2.36. □

PARAMETRIZED HIGHER CATEGORY THEORY

JAY SHAH

Abstract. We develop foundations for the theory of ∞-categories parametrized by a base ∞-category. Our main contribution is a theory of indexed homotopy limits and colimits, which specializes to a theory of G-colimits for G a finite group when the base is chosen to be the orbit category of G. We apply this theory to show that the G-∞-category of G-spaces is freely generated under G-colimits by the contractible G-space, thereby affirming a conjecture of Mike Hill.

Contents

1. Introduction

Motivation from equivariant homotopy theory: This paper lays foundations for a theory of ∞-categories parametrized by a base ∞-category S. Our interest in this project originates in attempting to locate the core homotopy theories of interest in equivariant homotopy theory - those of G-spaces and G-spectra - within the appropriate ∞-categorical framework. To explain, let G be a finite group and let us review the definitions of the ∞-categories of G-spaces and G-spectra, with a view towards endowing them with universal properties.

Consider a category $\mathbf{Top}_G$ of (nice) topological spaces equipped with G-action, with morphisms given by the G-equivariant continuous maps. There are various homotopy theories that derive from this category, depending on the class of weak equivalences that one chooses to invert. At one end, we can invert the class $\mathcal{W}_1$ of G-equivariant maps which induce a weak homotopy equivalence of underlying topological spaces, forgetting the G-action. If we let $\mathbf{Spc}$ denote the ∞-category of spaces (i.e., ∞-groupoids), then inverting $\mathcal{W}_1$ obtains the *∞-category of spaces with G-action*

$$\mathbf{Top}_G[\mathcal{W}_1^{-1}] \simeq \mathrm{Fun}(BG, \mathbf{Spc}).$$

For many purposes, $\mathrm{Fun}(BG, \mathbf{Spc})$ is the homotopy theory that one wishes to contemplate, but here we instead highlight its main deficiency. Namely, passing to this homotopy theory blurs the distinction between homotopy fixed points and actual fixed points, in that the functor $\mathbf{Top}_G \longrightarrow \mathrm{Fun}(BG, \mathbf{Spc})$ forgets the homotopy types of the various spaces X^H for H a nontrivial subgroup of G. Because many arguments in equivariant homotopy theory involve comparing X^H with the homotopy fixed points X^{hH}, we want to retain this data. To this end, we can instead let $\mathcal{W}$ be the class of G-equivariant maps which induce an equivalence on H-fixed points for every subgroup H of G. Let $\mathbf{Spc}_G := \mathbf{Top}_G[\mathcal{W}^{-1}]$; this is the *$\infty$-category of G-spaces.*

Like with $\mathbf{Top}_G[\mathcal{W}_1^{-1}]$, we would like a description of $\mathbf{Spc}_G$ which eliminates any reference to topological spaces with G-action, for the purpose of comprehending its universal property. Elmendorf's theorem grants such a description: we have

$$\mathbf{Spc}_G \simeq \mathrm{Fun}(\mathbf{O}_G^{op}, \mathbf{Spc}),$$

where $\mathbf{O}_G$ is the category of orbits of the group G. Thus, as an ∞-category, $\mathbf{Spc}_G$ is the *free cocompletion* of $\mathbf{O}_G$.

It is a more subtle matter to define the homotopy theory of G-spectra. There are at least three possibilities:

(1) The ∞-category of *Borel G-spectra*, i.e. spectra with G-action: This is
$$\mathbf{Sp}^{hG} := \mathrm{Fun}(BG, \mathbf{Sp}),$$
which is the stabilization of $\mathrm{Fun}(BG, \mathbf{Spc})$.

(2) The ∞-category of *'naive' G-spectra*, i.e. spectral presheaves on $\mathbf{O}_G$: This is
$$\mathbf{Sp}_G := \mathrm{Fun}(\mathbf{O}_G^{op}, \mathbf{Sp}),$$
which is the stabilization of $\mathbf{Spc}_G$.[1]

(3) The ∞-category of *'genuine' G-spectra*, i.e. spectral Mackey functors on the category $\mathbf{F}_G$ of finite G-sets: Let $A^{eff}(\mathbf{F}_G)$ be the effective Burnside $(2,1)$-category of G, given by taking as objects finite G-sets, as morphisms spans of finite G-sets, and as 2-morphisms isomorphisms between spans. Then, the ∞-category of genuine G-spectra is defined to be
$$\mathbf{Sp}^G := \mathrm{Fun}^{\oplus}(A^{eff}(\mathbf{F}_G), \mathbf{Sp}),$$
the ∞-category of direct-sum preserving functors from $A^{eff}(\mathbf{F}_G)$ to $\mathbf{Sp}$.[2]

The third possibility incorporates essential examples of cohomology theories for G-spaces, such as equivariant K-theory, because G-spectra in this sense possess transfers along maps of finite G-sets, encoded by the covariant maps in $A^{eff}(\mathbf{F}_G)$. It is thus what homotopy theorists customarily mean by G-spectra. However, from a categorical perspective it is a more mysterious object than the ∞-category of naive G-spectra, since it is *not* the stabilization of G-spaces. We are led to ask:

Question: What is the universal property of $\mathbf{Sp}^G$? More precisely, we have an adjunction
$$\Sigma^\infty_+ : \mathbf{Spc}_G \rightleftarrows \mathbf{Sp}^G : \Omega^\infty$$
with the right adjoint given by taking $\Omega^\infty : \mathbf{Sp} \longrightarrow \mathbf{Spc}$ objectwise and restricting along the evident map $\mathbf{O}_G^{op} \longrightarrow A^{eff}(\mathbf{F}_G)$, and we would like a universal property for Σ^∞_+ or Ω^∞.

Put another way, what is the categorical procedure which manufactures $\mathbf{Sp}^G$ from $\mathbf{Spc}_G$?

The key idea is that for this procedure of 'G-stabilization' one needs to enforce 'G-additivity' over and above the usual additivity satisfied by a stable ∞-category: that is, one wants the coincidence of coproducts and products indexed not just by finite sets but by finite sets with G-action. Reflecting upon the possible homotopical meaning of such a G-(co)product, we see that for a transitive G-set G/H, $\coprod_{G/H}$ and $\prod_{G/H}$ should be interpreted to mean the left and right adjoints to the restriction functor $\mathbf{Sp}^G \longrightarrow \mathbf{Sp}^H$, i.e. the induction and coinduction functors, and G-additivity then becomes the Wirthmüller isomorphism. In particular, we see that G-additivity is not a property that $\mathbf{Sp}^G$ can be said to enjoy in isolation, but rather one satisfied by the *presheaf* $\underline{\mathbf{Sp}}^G$ of ∞-categories indexed by $\mathbf{O}_G$; here, for every G-orbit U, a choice of basepoint specifying an isomorphism $U \cong G/H$ yields an equivalence $\underline{\mathbf{Sp}}^G(U) \simeq \mathbf{Sp}^H$, and the functoriality in maps of orbits is that of conjugation and

[1]The usage of a subscript G to indicate presheaves on $\mathbf{O}_G$ (whether valued in spaces or spectra) is consistent with our later notation for the S-category of S-objects in an arbitrary ∞-category – see Construction 3.9.

[2]This is not the definition which first appeared in the literature for G-spectra, but it is equivalent to e.g. the homotopy theory of orthogonal G-spectra by the pioneering work of Guillou-May [7]. For an ∞-categorical treatment, see [1].

restriction (in particular, recording the residual actions of the Weyl groups on $\mathbf{Sp}^H$). Correspondingly, we must rephrase our question so as to inquire after the universal property of the *morphism of* $\mathbf{O}_G$*-presheaves*

$$\underline{\Sigma}^\infty_+ : \underline{\mathbf{Spc}}_G \longrightarrow \underline{\mathbf{Sp}}^G,$$

where $\underline{\Sigma}^\infty_+$ is objectwise given by genuine H-suspension ranging over all subgroups $H \leq G$.

We now pause to observe that for the purpose of this analysis the group G is of secondary importance as compared to its associated category of orbits $\mathbf{O}_G$. Indeed, we focused on G-additivity as the distinguishing feature of genuine vs. naive G-spectra, as opposed to the invertibility of representation spheres, in order to evade representation theoretic aspects of equivariant stable homotopy theory. In order to frame our situation in its proper generality, let us now dispense with the group G and replace $\mathbf{O}_G$ by an arbitrary ∞-category T. Call a presheaf of ∞-categories on T a *T-category.* The *T-category of T-spaces* $\underline{\mathbf{Spc}}_T$ is given by the functor $T^{op} \longrightarrow \mathbf{Cat}_\infty$, $t \mapsto \mathrm{Fun}((T^{/t})^{op}, \mathbf{Spc})$. Note that this specializes to $\underline{\mathbf{Spc}}_G$ when $T = \mathbf{O}_G$ because $\mathbf{O}_H \simeq (\mathbf{O}_G)^{/(G/H)}$; slice categories stand in for subgroups in our theory. With the theory of T-colimits advanced in this paper, we can then supply a universal property for $\underline{\mathbf{Spc}}_T$ *as a T-category.* Write $\underline{\mathrm{Fun}}_T$ for the internal hom in the ∞-category of T-categories, which is cartesian closed.

1.1. **Theorem.** *Suppose T is any ∞-category. Then $\underline{\mathbf{Spc}}_T$ is T-cocomplete, and for any T-category E which is T-cocomplete, the T-functor of evaluation at the T-final object*[3]

$$\underline{\mathrm{Fun}}^L_T(\underline{\mathbf{Spc}}_T, E) \longrightarrow \underline{\mathrm{Fun}}_T(*_T, E) \simeq E$$

induces an equivalence from the T-category of T-functors $\underline{\mathbf{Spc}}_T \longrightarrow E$ which strongly preserve T-colimits to E. In other words, $\underline{\mathbf{Spc}}_T$ is freely generated under T-colimits by the final T-category.

1.2. **Remark.** The notion of T-cocompleteness needed for the theorem is slightly more elaborate than one might naively expect. Namely, we say that a T-category C is *T-cocomplete* if for all $t \in T$, the pullback of C to a $T^{/t}$-category $C_{\underline{t}}$ (Notation 2.29) admits all (small) $T^{/t}$-colimits (Definition 5.13). Correspondingly, we say that a T-functor $F : C \longrightarrow D$ strongly preserves T-colimits if for all $t \in T$, the pulled-back $T^{/t}$-functor $F_{\underline{t}} : C_{\underline{t}} \longrightarrow D_{\underline{t}}$ preserves all $T^{/t}$-colimits (Definition 11.2).

When $T = \mathbf{O}_G$, this result was originally conjectured by Mike Hill.

To go further and define T-spectra, we need a condition on T so that it supports a theory of spectral Mackey functors. We say that T is *orbital* if T admits multipullbacks, by which we mean that its finite coproduct completion $\mathbf{F}_T$ admits pullbacks. The purpose of the orbitality assumption is to ensure that the effective Burnside category $A^{\mathit{eff}}(\mathbf{F}_T)$ is well-defined. Note that the slice categories $T_{/t}$ are orbital if T is. We define the *T-category of T-spectra* $\underline{\mathbf{Sp}}^T$ to be the functor $T^{op} \longrightarrow \mathbf{Cat}_\infty$ given by $t \mapsto \mathrm{Fun}^\oplus(A^{\mathit{eff}}(\mathbf{F}_{T_{/t}}), \mathbf{Sp})$. We then have the following theorem of Denis Nardin concerning $\underline{\mathbf{Sp}}^T$ from [16], which resolves our question:

1.3. **Theorem** ([16, Theorem 7.4])**.** *Suppose T is an atomic*[4] *orbital ∞-category. Then $\underline{\mathbf{Sp}}^T$ is T-stable, and for any pointed T-category C which has all finite T-colimits, the functor of postcomposition by Ω^∞*

$$(\Omega^\infty)_* : \mathrm{Fun}^{T-rex}_T(C, \underline{\mathbf{Sp}}^T) \longrightarrow \mathrm{Lin}^T(C, \underline{\mathbf{Spc}}_T)$$

induces an equivalence from the ∞-category of T-functors $C \longrightarrow \underline{\mathbf{Sp}}^T$ which preserve finite T-colimits to the ∞-category of T-linear functors $C \longrightarrow \underline{\mathbf{Spc}}_T$, i.e. those T-functors which are fiberwise linear and send finite T-coproducts to T-products.

We hope that the two aforementioned theorems will serve to impress upon the reader the utility of the purely ∞-categorical work that we undertake in this paper.

1.4. **Warning.** In contrast to this introduction thus far and the conventions adopted elsewhere (e.g. in [16]), we will henceforth speak of S-categories, S-colimits, etc. for $S = T^{op}$.

[3] We define $*_T$ to be the constant T-presheaf valued at $*$, which is the final object in the ∞-category of T-categories.

[4] This is an additional technical hypothesis which we do not explain here. It will not concern us in the body of the paper.

What is parametrized ∞-category theory? Roughly speaking, parametrized ∞-category theory is an interpretation of the familiar notions of ordinary or 'absolute' ∞-category theory within the $(\infty, 2)$-category of functors $\mathrm{Fun}(S, \mathbf{Cat}_\infty)$, done relative to a fixed 'base' ∞-category S. By 'interpretation', we mean something along the lines of the program of Emily Riehl and Dominic Verity [17], which axiomatizes the essential properties of an $(\infty, 2)$-category that one needs to do formal category theory into the notion of an ∞-*cosmos*, of which $\mathrm{Fun}(S, \mathbf{Cat}_\infty)$ is an example. In an ∞-cosmos, one can write down in a formal way notions of limits and colimits, adjunctions, Kan extensions, and so forth. Working out what this means in the example of $\mathbf{Cat}_\infty$-valued functors is the goal of this paper. In the classical 2-categorical setting, such limits and colimits are referred to as "indexed" limits and colimits, so another perspective on this paper is that it extends indexed category theory to the ∞-categorical setting.

In contrast to Riehl–Verity, we will work within the model of *quasi-categories* and not hesitate to use special aspects of our model (e.g., combinatorial arguments involving simplicial sets). We are motivated in this respect by the existence of a highly developed theory of *cocartesian fibrations* due to Jacob Lurie, which we review in §2. Cocartesian fibrations are our preferred way to model $\mathbf{Cat}_\infty$-valued functors, for two reasons:

(1) The data of a functor $F : S \longrightarrow \mathbf{Cat}_\infty$ is overdetermined vs. that of a cocartesian fibration over S, in the sense that to define F one must prescribe an infinite hierarchy of coherence data, which under the functor-fibration correspondence amounts to prescribing an infinite sequence of compatible horn fillings.[5] Because of this, specifying a cocartesian fibration (which one ultimately needs to do in order to connect our theory to applications) is typically an easier task than specifying the corresponding functor to $\mathbf{Cat}_\infty$.

(2) The Grothendieck construction on a functor $S \longrightarrow \mathbf{Cat}_\infty$ is made visible in the cocartesian fibration setup, as the total category of the cocartesian fibration. Many of our arguments involve direct manipulation of the Grothendieck construction, in order to relate or reduce notions of parametrized ∞-category theory to absolute ∞-category theory.

We have therefore tailored our exposition to the reader familiar with the first five chapters of [10]; the only additional major prerequisite is the part of [12, App. B] dealing with variants of the cocartesian model structure of [10, §3] and functoriality in the base.

Linear overview. Let us now give a section-by-section summary of the contents of this paper.

(§2) We define an S-*category* as a cocartesian fibration over S, and then collect some necessary preliminaries on cocartesian fibrations and model structures on categories of marked simplicial sets. In particular, we recapitulate Lurie's theorem that establishes conditions under which change-of-base adjunctions are Quillen (Theorem 2.24); this theorem will allow us to efficiently verify the fibrancy of many of the simplicial set constructions introduced in this paper.

(§3) We first define and study the internal hom $\underline{\mathrm{Fun}}_S(-,-)$ of S-categories (Definition 3.2). We then recall the S-*category of* S-*objects* $\underline{E}_S$ in an ∞-category E from [2] (Construction 3.9), which computes the right adjoint to the forgetful functor $[C \longrightarrow S] \mapsto C$. When $S = \mathbf{O}_G^{op}$ and $E = \mathbf{Spc}$, this recovers the G-category of G-spaces $\underline{\mathbf{Spc}}_G$.

(§4) We first introduce the S-join $(- \star_S -)$ (Definition 4.1), which in terms of presheaves computes the fiberwise join. We then define and study two (canonically equivalent) S-slice constructions: for a S-functor $p : K \longrightarrow C$, we have S-undercategories $C_{(p,S)/}$ and $C^{(p,S)/}$ and S-overcategories $C_{/(p,S)}$ and $C^{/(p,S)}$. The 'lower' construction (Definition 4.17) is a direct generalization of Joyal's slice construction (cf. [10, Proposition 1.2.9.2]) and participates in a Quillen adjunction with the S-join. The 'upper' construction (Definition 4.26) proceeds by taking an S-fiber of the relevant map of S-functor categories. In practice, the upper S-slice is far easier to work with as its definition is less bound up with the intricate combinatorics of the S-join (which need to be thoroughly understood to even establish the fibrancy of the lower S-slice; cf. Proposition 4.11). However, it is easier to establish the universal mapping property of the S-slice using its lower incarnation (Proposition 4.25).

[5] It is for this reason that one speaks of *straightening* a cocartesian fibration to a functor.

(§5) We initiate our study of S-colimits and S-limits by giving the basic definition 5.2, and then discuss a few special cases: S-(co)limits in an S-category of S-objects, S-colimits indexed by constant S-diagrams, and S-colimits indexed by S-points (i.e., S-coproducts). We then explain how to deduce results about S-limits from S-colimits (or vice-versa) by means of the vertical opposite construction (Corollary 5.25).

(§6) Our main goal in this section is to establish an S-analogue of Joyal's cofinality theorem [10, Theorem 4.1.3.1]: an S-functor $C \longrightarrow D$ is *S-final* if and only if it is fiberwise final[6] (Theorem 6.7). Our strategy is to control the functoriality encoded by the S-slice category in terms of a construction, the *twisted slice* (Definition 6.5), fibered over the twisted arrow category $\widetilde{\mathcal{O}}(S)$; the right Kan extension of the latter will then obtain the former (Theorem 6.6). In fact, we first do the same for the internal hom $\underline{\mathrm{Fun}}_S$ itself (Equation 6.3.1). This may be thought of as a refinement of the end formula for an ∞-category of natural transformations (cf. Remark 6.4).

(§7) In this brief section, we introduce the notions of S-fibration, S-(co)cartesian fibration, and S-bifibration (Definition 7.1 and Definition 7.9). We also introduce the free S-(co)cartesian fibration as an example (Definition 7.6).

(§8) We recall Lurie's definition of a relative adjunction and specialize it to the notion of an S-adjunction (Definition 8.3). We then prove a number of fundamental results about S-adjunctions —most notably, the fact that a left S-adjoint preserve S-colimits (Corollary 8.9).

(§9) Given an S-cocartesian fibration $\phi : C \longrightarrow D$ and an S-functor $F : C \longrightarrow E$, we construct the left S-Kan extension $\phi_! F : D \longrightarrow E$, which will also call the *D-parametrized S-colimit* of F. With our assumption on ϕ, we have that for every object $x \in D_s$, $(\phi_! F)(x)$ is computed as the $S^{s/}$-colimit of the restriction of F to the $S^{s/}$-fiber $C_{\underline{x}}$; this is precisely analogous to the situation where the left Kan extension along a cocartesian fibration is computed by taking colimits fiberwise. In order to construct $\phi_! F$, we need to solve the coherence problem of assembling the individual $S^{s/}$-colimits of $F_{\underline{s}} : C_{\underline{x}} \longrightarrow E_{\underline{s}}$ (ranging over all $x \in D_s$) into a single S-functor out of D. We introduce the S-pairing construction 9.1, and subsequently the D-parametrized slice (Construction 9.8), to facilitate this. The problem of constructing $\phi_! F$ then ultimately reduces to choosing a section of a certain trivial Kan fibration defined in terms of the D-parametrized slice (Theorem 9.15).

(§10) We define left S-Kan extensions in general (Definition 10.1) and prove the basic existence and uniqueness result about them (Theorem 10.3). In contrast to the brutal simplex-by-simplex approach taken in [10, §4.3.2] to the construction of Kan extensions (cf. [10, Lemma 4.3.2.13]), we instead reduce to the solved coherence problem for D-parametrized S-colimits via factoring the S-functor $\phi : C \longrightarrow D$ to be extended along through the free S-cocartesian fibration on it. We remark that, to our knowledge, the approach of §9 and §10 gave a novel[7] and more conceptual construction of Kan extensions even in the context of ordinary ∞-category theory. Lurie has since independently written up a treatment of (relative) Kan extensions along these lines in Kerodon [13, Tag 02Y1].

(§11) We recall the S-category of presheaves $\mathbf{P}_S(-)$, prove the S-Yoneda lemma 11.1, discuss S-mapping spaces, and establish the universal property of $\mathbf{P}_S(-)$ as free S-cocompletion (Theorem 11.5), thereby proving Theorem 1.1.

(§12) We prove two Bousfield-Kan style[8] decomposition results that express an arbitrary S-colimit as a geometric realization of either S-coproducts or S-space-indexed S-colimits (Theorem 12.13 and Theorem 12.6). The essential content behind such formulas lies in replacing a given diagram C with one fibered over $\Delta^{op} \times S$ that possesses an S-final map to C. As a warmup, we first explain how this goes when S is a point (Corollary 12.3 and Corollary 12.5); the resulting formula appears to be new in the case of coproducts, whereas the case of spaces was first obtained by Aaron Mazel-Gee in [15]. We then apply the S-Bousfield-Kan formula to show

[6] We write final and initial for what Lurie calls (left) cofinal and right cofinal, respectively.

[7] All these results date to 2017.

[8] By this, we mean to refer to generalizations of the classical formula for writing a colimit as a coequalizer of coproducts, which were studied by Bousfield and Kan in the context of homotopy colimits with coequalizers replaced by geometric realization.

that, supposing S^{op} admits multipullbacks, an S-category is S-cocomplete if and only if it admits all S-(co)products and geometric realizations (Corollary 12.15).

Notation and conventions. Let C be an ∞-category. We write

$$\mathcal{O}(C) := \mathrm{Fun}(\Delta^1, C)$$

for the ∞-category of arrows in C. In this paper, we will frequently encounter fiber products of the form

$$A \times_{F,C,\mathrm{ev}_0} \mathcal{O}(C) \times_{\mathrm{ev}_1,C,G} B$$

where $F : A \longrightarrow C$ and $G : B \longrightarrow C$ are functors. To avoid notational clutter, we adopt the global convention that, unless otherwise decorated, fiber products with the source functor ev_0 are to be written on the left, and fiber products with the target functor ev_1 are to written on the right. Moreover, we will drop F and G from the notation if they are understood from context. For instance, we would write the preceding expression as $A \times_C \mathcal{O}(C) \times_C B$.

Acknowledgements. This paper is a lightly revised version of my thesis, which was originally part of a joint project with my advisor Clark Barwick, Emanuele Dotto, Saul Glasman, and Denis Nardin. I would like to thank them and the other participants of the Bourbon seminar - Lukas Brantner, Peter Haine, Marc Hoyois, Akhil Mathew, and Sune Precht Reeh - for innumerable conversations and mathematical inspiration, without which this work would not have been possible. I would also like to thank the referee for writing an extremely detailed report that has helped to improve the readability of this paper.

2. Cocartesian fibrations and model categories of marked simplicial sets

Let S be an ∞-category. In this section, we give a rapid review of the theory of cocartesian fibrations and the surrounding apparatus of marked simplicial sets. This primarily serves to fix some of our notation and conventions for the remainder of the paper; for a more detailed exposition of these concepts, we refer the reader to [5]. In particular, the reader should be aware of our special notation (Notation 2.29) for the S-fibers of a S-functor.

Cocartesian fibrations. We begin with the basic definitions:

2.1. **Definition.** Let $\pi : X \longrightarrow S$ be a map of simplicial sets. Then π is a *cocartesian fibration* if

(1) π is an *inner fibration*: for every $n > 1$, $0 < k < n$ and commutative square

$$\begin{array}{ccc} \Lambda^n_k & \longrightarrow & X \\ \downarrow & \nearrow & \downarrow \pi \\ \Delta^n & \longrightarrow & S, \end{array}$$

the dotted lift exists.

(2) For every edge $\alpha : s_0 \to s_1$ in S and $x_0 \in X$ with $\pi(x_0) = s_0$, there exists an edge $e : x_0 \to x_1$ in X with $\pi(e) = \alpha$, such that e is π-*cocartesian*: for every $n > 1$ and commutative square

$$\begin{array}{ccc} \Lambda^n_0 & \xrightarrow{f} & X \\ \downarrow & \nearrow & \downarrow \pi \\ \Delta^n & \longrightarrow & S \end{array}$$

with $f|_{\Delta^{\{0,1\}}} = e$, the dotted lift exists.

Dually, π is a *cartesian fibration* if π^{op} is a cocartesian fibration.

A cocartesian resp. cartesian fibration $\pi : X \longrightarrow S$ is said to be a *left* resp. *right* fibration if for every object $s \in S$ the fiber X_s is a Kan complex.

Now suppose $\pi : X \longrightarrow S$ and $\rho : Y \longrightarrow S$ are (co)cartesian fibrations. Then a *map of (co)cartesian fibrations* $f : X \longrightarrow Y$ is a map of simplicial sets such that $\rho \circ f = \pi$ and f carries π-(co)cartesian edges to ρ-(co)cartesian edges. The collection of cocartesian fibrations over S and maps thereof organize into a subcategory $\mathbf{Cat}^{cocart}_{\infty/S}$ of the overcategory $\mathbf{Cat}_{\infty/S}$.

In this paper, owing to the importance of these notions we see fit to introduce more concise and suggestive terminology for cocartesian fibrations and left fibrations over S.

2.2. **Definition.** An *S-category* resp. *S-space* C is a cocartesian resp. left fibration $\pi : C \longrightarrow S$. An *$S$-functor* $F : C \longrightarrow D$ between S-categories C and D is a map of cocartesian fibrations over S.

Given an S-category $\pi : C \longrightarrow S$, an *$S$-subcategory* $D \subset C$ is a subcategory such that the restriction $\pi|_D$ is a cocartesian fibration and an edge in D is $\pi|_D$-cocartesian if and only if it is π-cocartesian. The inclusion functor then necessarily preserves cocartesian edges, so is an S-functor. We further say that D is a *full S-subcategory* if $D \subset C$ is in addition a full subcategory, or equivalently, for every $s \in S$, $D_s \subset C_s$ is a full subcategory.

2.3. **Example** (Arrow ∞-categories)**.** The arrow ∞-category $\mathcal{O}(S)$ of S is cocartesian over S via the target morphism ev_1, and cartesian over S via the source morphism ev_0. An edge

$$e : [s_0 \to t_0] \longrightarrow [s_1 \to t_1]$$

in $\mathcal{O}(S)$ is ev_1-cocartesian resp. ev_0-cartesian if and only if $\mathrm{ev}_0(e)$ resp. $\mathrm{ev}_1(e)$ is an equivalence in S.

The fiber of $\mathrm{ev}_0 : \mathcal{O}(S) \longrightarrow S$ over s is isomorphic to Lurie's 'alternative' slice ∞-category $S^{s/}$. Using our knowledge of the ev_1-cocartesian edges, we see that ev_1 restricts to a left fibration $S^{s/} \longrightarrow S$. In the terminology of [10, Proposition 4.4.4.5], this is a *corepresentable* left fibration. We will refer to the corepresentable left fibrations as *S-points*. Further emphasizing this viewpoint, we will often let $\underline{s}$ denote $S^{s/}$.

To a beginner, the lifting conditions of Definition 2.1 can seem opaque. Under our standing assumption that S is an ∞-category, we have a reformulation of the definition of cocartesian edge, and hence that of cocartesian fibration, which serves to illuminate its homotopical meaning.

2.4. **Proposition.** *Let $\pi : X \longrightarrow S$ be an inner fibration (so X is an ∞-category). Then an edge $e : x_0 \to x_1$ in X is π-cocartesian if and only if for every $x_2 \in X$, the commutative square of mapping spaces*

$$\begin{array}{ccc} \mathrm{Map}_X(x_1, x_2) & \xrightarrow{e^*} & \mathrm{Map}_X(x_0, x_2) \\ \downarrow{\scriptstyle \pi} & & \downarrow{\scriptstyle \pi} \\ \mathrm{Map}_S(\pi(x_1), \pi(x_2)) & \xrightarrow{\pi(e)^*} & \mathrm{Map}_S(\pi(x_0), \pi(x_2)) \end{array}$$

is homotopy cartesian.

With some work, Proposition 2.4 can be used to supply an alternative, model-independent definition of a cocartesian fibration: we refer to Mazel-Gee's paper [14] for an exposition along these lines.

2.5. **Example** ([10, §3.2.2])**.** Let $\mathbf{Cat}_\infty$ denote the (large) ∞-category of (small) ∞-categories. Then there exists a *universal cocartesian fibration* $\mathcal{U} \longrightarrow \mathbf{Cat}_\infty$, which is characterized up to contractible choice by the requirement that any cocartesian fibration $\pi : X \longrightarrow S$ (with essentially small fibers) fits into a homotopy pullback square

$$\begin{array}{ccc} X & \longrightarrow & \mathcal{U} \\ \downarrow{\scriptstyle \pi} & & \downarrow \\ S & \xrightarrow{F_\pi} & \mathbf{Cat}_\infty. \end{array}$$

Concretely, one can take $\mathcal{U}$ to be the subcategory of the arrow category $\mathcal{O}(\mathbf{Cat}_\infty)$ spanned by the representable right fibrations and morphisms thereof.

As suggested by Example 2.5, the functor

$$\mathrm{Fun}(S, \mathbf{Cat}_\infty) \longrightarrow \mathbf{Cat}_{\infty/S}^{cocart}$$

given by pulling back $\mathcal{U} \longrightarrow \mathbf{Cat}_\infty$ is an equivalence. The composition

$$\mathrm{Gr} : \mathrm{Fun}(S, \mathbf{Cat}_\infty) \xrightarrow{\simeq} \mathbf{Cat}_{\infty/S}^{cocart} \subset \mathbf{Cat}_{\infty/S}$$

is the *Grothendieck construction* functor. Since equivalences in $\mathrm{Fun}(S, \mathbf{Cat}_\infty)$ are detected objectwise, Gr is conservative. Moreover, one can check that Gr preserves limit and colimits, so by the adjoint functor theorem Gr admits both a left and a right adjoint.

2.6. **Notation.** Let

$$\mathrm{Fr} \dashv \mathrm{Gr} \dashv H$$

denote the left and right adjoints of Gr.

We call Fr the *free cocartesian fibration* functor (see also [6]): concretely, one has

$$\mathrm{Fr}(X \longrightarrow S) = X \times_S \mathcal{O}(S) \xrightarrow{ev_1} S,$$

or as a functor $s \mapsto X \times_S S_{/s}$ with functoriality obtained from $S_{/(-)}$. The functor H can also be concretely described using its universal mapping property: since $\mathrm{Fr}(\{s\} \subset S) = S_{s/}$, the fiber $H(X)_s$ is given by $\mathrm{Fun}_{/S}(S_{s/}, X)$, and the functoriality in S is obtained from that of $S_{(-)/}$.

A model structure for cocartesian fibrations. We want a model structure which has as its fibrant objects the cocartesian fibrations over a fixed simplicial set. However, it is clear that to define it we need some way to remember the data of the cocartesian edges. This leads us to introduce *marked simplicial sets*.

2.7. **Definition.** A marked simplicial set $(X, \mathcal{E})$ is the data of a simplicial set X and a subset $\mathcal{E} \subset X_1$ of the edges of X, such that $\mathcal{E}$ contains all of the degenerate edges. We call $\mathcal{E}$ the set of *marked edges* of X. A map of marked simplicial sets $f : (X, \mathcal{E}) \longrightarrow (Y, \mathcal{F})$ is a map of simplicial sets $f : X \longrightarrow Y$ such that $f(\mathcal{E}) \subset \mathcal{F}$.

2.8. **Notation.** We introduce notation for certain classes of marked simplicial sets. Let X be a simplicial set.

- $X^\flat$ is X with only the degenerate edges marked. To avoid notational clutter, we will sometimes suppress this notation and simply write X for $X^\flat$.
- $X^\sharp$ is X with all of its edges marked.
- Suppose that X is an ∞-category. Then $X^\sim$ is X with its equivalences marked.
- Suppose that $\pi : X \longrightarrow S$ is an inner fibration. Then ${}_\natural X$ is X with its π-cocartesian edges marked, and $X^\natural$ is X with its π-cartesian edges marked.
- Let $n > 0$. Let ${}_\natural\Delta^n$ resp. ${}_\natural\Lambda^n_0$ denote Δ^n resp. Λ^n_0 with the edge $\{0, 1\}$ marked (if it exists, i.e. excluding Δ^0 and $\Lambda^1_0 = \{0\}$) along with the degenerate edges. Dually, let $\Delta^{n\natural}$ resp. $\Lambda^{n\natural}_n$ denote Δ^n resp. Λ^n_n with the edge $\{n-1, n\}$ marked.

Note that our choice of notation ${}_\natural\Delta^n$ and ${}_\natural\Lambda^n_0$ is not meant to be interpreted as a special instance of marking cocartesian edges (though the map $\Delta^n \longrightarrow \Delta^1$ given by $0 \mapsto 0$ and $1, ..., n \mapsto 1$ renders it as such for the former); rather, we mean to indicate that the relevant lifting problem for a cocartesian fibration as a marked simplicial set is to lift along the marked horn inclusion ${}_\natural\Lambda^n_0 \longrightarrow {}_\natural\Delta^n$ (cf. Definition 2.9 below), and vice-versa for cartesian fibrations and $\Lambda^{n\natural}_n \longrightarrow \Delta^{n\natural}$.

For the rest of this section, fix a marked simplicial set $(Z, \mathcal{E})$ where Z is an ∞-category and $\mathcal{E}$ contains all of the equivalences in Z; in our applications, Z will generally be some type of fibration over S. Let $s\mathbf{Set}^+_{/(Z,\mathcal{E})}$ denote the category of marked simplicial sets over $(Z, \mathcal{E})$; following Lurie [10, Notation 3.1.0.2], we will also denote $s\mathbf{Set}^+_{/Z^\sharp}$ more simply as $s\mathbf{Set}^+_{/Z}$. We will frequently abuse notation by referring an object $\pi : (X, \mathcal{F}) \longrightarrow (Z, \mathcal{E})$ of $s\mathbf{Set}^+_{/(Z,\mathcal{E})}$ by its domain $(X, \mathcal{F})$, or even just by X.

2.9. **Definition.** An object $(X, \mathcal{F})$ in $s\mathbf{Set}^+_{/(Z,\mathcal{E})}$ is $(Z, \mathcal{E})$-*fibered*[9] if

(1) $\pi : X \longrightarrow Z$ is an inner fibration.
(2) For every $n > 0$ and commutative square

$$\begin{array}{ccc} {}_\natural\Lambda^n_0 & \longrightarrow & (X, \mathcal{F}) \\ \downarrow & \nearrow & \downarrow \\ {}_\natural\Delta^n & \longrightarrow & (Z, \mathcal{E}), \end{array}$$

[9]This differs from [12, Definition B.0.19], but nonetheless defines the correct class of anodyne morphisms [12, Definition B.1.1].

a dotted lift exists. In other words, letting $n = 1$, π-cocartesian lifts exist over marked edges in Z, and letting $n > 1$, marked edges in X are π-cocartesian.[10]

(3) For every commutative square

$$\begin{array}{ccc} (\Lambda^2_1)^\sharp \cup_{(\Lambda^2_1)^\flat} (\Delta^2)^\flat & \longrightarrow & (X, \mathcal{F}) \\ \downarrow & \nearrow & \downarrow \\ (\Delta^2)^\sharp & \longrightarrow & (Z, \mathcal{E}), \end{array}$$

a dotted lift exists. In other words, marked edges are closed under composition.[11]

(4) Let $Q = \Delta^0 \coprod_{\Delta^{\{0,2\}}} \Delta^3 \coprod_{\Delta^{\{1,3\}}} \Delta^0$. For every commutative square

$$\begin{array}{ccc} Q^\flat & \longrightarrow & (X, \mathcal{F}) \\ \downarrow & \nearrow & \downarrow \\ Q^\sharp & \longrightarrow & (Z, \mathcal{E}), \end{array}$$

a dotted lift exists. Since we assumed that $\mathcal{E}$ contains all equivalences in Z, this implies that all equivalences in X are marked.

2.10. **Example.** Let $\pi : X \longrightarrow Z$ be an inner fibration. Comparing with Definition 2.1, it is clear that $(X, \mathcal{F})$ is $Z^\sharp$-fibered if and only if π is a cocartesian fibration and $(X, \mathcal{F}) = {}_\natural X$. At the other extreme, $(X, \mathcal{F})$ is $Z^\sim$-fibered if and only if π is a categorical fibration and $(X, \mathcal{F}) = X^\sim$.

Recall that a model structure, if it exists, is determined by its cofibrations and fibrant objects. Collecting results of Lurie from [12, App. B], we now define a model structure on $s\mathbf{Set}^+_{/(Z,\mathcal{E})}$ with cofibrations the monomorphisms and fibrant objects given by the $(Z, \mathcal{E})$-fibered objects.

2.11. **Definition.** Define functors[12]

$$\mathrm{Map}_Z(-,-) : s\mathbf{Set}^{+\,op}_{/(Z,\mathcal{E})} \times s\mathbf{Set}^+_{/(Z,\mathcal{E})} \longrightarrow s\mathbf{Set}$$
$$\mathrm{Fun}_Z(-,-) : s\mathbf{Set}^{+\,op}_{/(Z,\mathcal{E})} \times s\mathbf{Set}^+_{/(Z,\mathcal{E})} \longrightarrow s\mathbf{Set}$$

by

$$\mathrm{Hom}(A, \mathrm{Map}_Z(X, Y)) = \mathrm{Hom}_{/(Z,\mathcal{E})}(A^\sharp \times X, Y),$$
$$\mathrm{Hom}(A, \mathrm{Fun}_Z(X, Y)) = \mathrm{Hom}_{/(Z,\mathcal{E})}(A^\flat \times X, Y).$$

2.12. **Definition.** A map $f : A \longrightarrow B$ in $s\mathbf{Set}^+_{/(Z,\mathcal{E})}$ is a *cocartesian equivalence* (with respect to $(Z, \mathcal{E})$) if the following equivalent conditions obtain:

(1) For all $(Z, \mathcal{E})$-fibered X, $f^* : \mathrm{Map}_Z(B, X) \longrightarrow \mathrm{Map}_Z(A, X)$ is an equivalence of Kan complexes.
(2) For all $(Z, \mathcal{E})$-fibered X, $f^* : \mathrm{Fun}_Z(B, X) \longrightarrow \mathrm{Fun}_Z(A, X)$ is an equivalence of ∞-categories.

2.13. **Theorem** ([12, Theorem B.0.20])**.** *There exists a left proper combinatorial model structure on the category $s\mathbf{Set}^+_{/(Z,\mathcal{E})}$, which we call the* ***cocartesian model structure****, such that:*

(1) The cofibrations are the monomorphisms.
(2) The weak equivalences are the cocartesian equivalences.
(3) The fibrant objects are the $(Z, \mathcal{E})$-fibered objects.

Dually, we define the ***cartesian model structure*** *on $s\mathbf{Set}^+_{/(Z,\mathcal{E})}$ to be the cocartesian model structure on $s\mathbf{Set}^+_{/(Z,\mathcal{E})^{op}}$ under the isomorphism given by taking opposites.*

[10]Note that condition (2) already guarantees that $X \longrightarrow Z$ is a cocartesian fibration if $\mathcal{E} = Z_1$; however, one additionally needs condition (4) to ensure that *all* of the π-cocartesian edges are marked in X.

[11]Strictly speaking, condition (3) by itself only guarantees that for any pair of composable marked edges, there exists a composite that is again marked. One additionally needs condition (4) to ensure that *all* compositions of marked edges are again marked.

[12]In [12, App. B], these functors are denoted as $\mathrm{Map}^\sharp_Z$ and $\mathrm{Map}^\flat_Z$ respectively.

2.14. **Remark.** The underlying ∞-category of $s\mathbf{Set}^+_{/(Z,\mathcal{E})}$ identifies as the subcategory of $\mathbf{Cat}_{\infty/Z}$ on those isofibrations[13] $X \longrightarrow Z$ that admit cocartesian lifts over $\mathcal{E}$, and with morphisms preserving cocartesian edges. In particular, passing to the closure of $\mathcal{E}$ under composition does not change the underlying ∞-category.

We have the following characterization of the cocartesian equivalences between fibrant objects (which is unsurprising, in light of the equivalence $\mathbf{Cat}^{cocart}_{\infty/Z} \simeq \mathrm{Fun}(Z, \mathbf{Cat}_\infty)$).

2.15. **Proposition** ([12, Lemma B.2.4])**.** *Let X and Y be fibrant objects in $s\mathbf{Set}^+_{/(Z,\mathcal{E})}$ equipped with the cocartesian model structure, and let $f : X \longrightarrow Y$ be a map in $s\mathbf{Set}^+_{/(Z,\mathcal{E})}$. Then the following are equivalent:*

(1) f is a cocartesian equivalence.
(2) f is a homotopy equivalence, i.e. f admits a homotopy inverse: there exists a map $g : Y \longrightarrow X$ and homotopies $h : (\Delta^1)^\sharp \times X \longrightarrow X$, $h' : (\Delta^1)^\sharp \times Y \longrightarrow Y$ in $s\mathbf{Set}^+_{/(Z,\mathcal{E})}$ connecting $g \circ f$ to id_X and $f \circ g$ to id_Y, respectively.
(3) f is a categorical equivalence.
(4) For every (not necessarily marked) edge $\alpha : \Delta^1 \longrightarrow Z$, $f_\alpha : \Delta^1 \times_Z X \longrightarrow \Delta^1 \times_Z Y$ is a categorical equivalence.

If every edge of Z is marked, then (4) can be replaced by the following apparently weaker condition:

(4′) For every object $z \in Z$, $f_z : X_z \longrightarrow Y_z$ is a categorical equivalence.

We also have the following characterization of the fibrations between fibrant objects.

2.16. **Proposition** ([12, Proposition B.2.7])**.** *Let $Y = (Y, \mathcal{F})$ be a fibrant object in $s\mathbf{Set}^+_{/(Z,\mathcal{E})}$ equipped with the cocartesian model structure, and let $f : X \longrightarrow Y$ be a map in $s\mathbf{Set}^+_{/(Z,\mathcal{E})}$. Then the following are equivalent:*

(1) f is a fibration.
(2) X is fibrant, and f is a categorical fibration.
(3) f is fibrant in $s\mathbf{Set}^+_{/(Y,\mathcal{F})}$.

2.17. **Corollary.** *Suppose $Z \longrightarrow S$ is a cocartesian fibration. Then the cocartesian model structure $s\mathbf{Set}^+_{/_\natural Z}$ coincides with the 'slice' model structure on $(s\mathbf{Set}^+_{/S})_{/_\natural Z}$ created by the forgetful functor to $s\mathbf{Set}^+_{/S}$ equipped with its cocartesian model structure.*

Proof. This immediately follows from Proposition 2.16. □

2.18. **Example.** Suppose that Z is a Kan complex. Then the cocartesian and cartesian model structures on $s\mathbf{Set}^+_{/Z}$ coincide. In particular, taking $Z = \Delta^0$, we will also refer to the cocartesian model structure on $s\mathbf{Set}^+$ as the *marked model structure*. Since this model structure on $s\mathbf{Set}^+$ is unambiguous, we will always regard $s\mathbf{Set}^+$ as equipped with it. Then the fibrant objects of $s\mathbf{Set}^+$ are precisely the ∞-categories with their equivalences marked.

2.19. **Example.** Suppose that $(Z, \mathcal{E}) = Z^\sim$. Then the cocartesian and cartesian model structures on $s\mathbf{Set}^+_{/Z^\sim}$ coincide. Moreover, we have a Quillen equivalence

$$(-)^\flat : (s\mathbf{Set}_{\mathrm{Joyal}})_{/Z} \rightleftarrows s\mathbf{Set}^+_{/Z^\sim} : U$$

where the functor U forgets the marking. In particular, $(-)^\flat$ sends categorical equivalences to marked equivalences.

2.20. **Example.** The inclusion functor $\mathbf{Spc} \subset \mathbf{Cat}_\infty$ admits left and right adjoints B and ι, where B is the classifying space functor that inverts all edges and ι is the 'core' functor that takes the maximal sub-∞-groupoid. These two adjunctions are modeled by the two Quillen adjunctions

$$U : s\mathbf{Set}^+ \rightleftarrows s\mathbf{Set}_{\mathrm{Quillen}} : (-)^\sharp,$$

[13]Note that with this choice, the resulting subcategory is not stable under equivalence. One could alternatively appeal to a homotopy-invariant notion of cocartesian fibration and instead replace isofibrations with functors – cf. [14], which admits an obvious generalization to this setting.

$$(-)^\sharp\colon s\mathbf{Set}_{\mathrm{Quillen}} \rightleftarrows s\mathbf{Set}^+ :M.$$

Here $M(X,\mathcal{E})$ is the maximal sub-simplicial set of X such that all of its edges are marked. In particular, $(-)^\sharp$ sends weak homotopy equivalences to marked equivalences.

2.21. **Proposition** ([12, Remark B.2.5]). *The bifunctor*

$$-\times - : s\mathbf{Set}^+_{/(Z_1,\mathcal{E}_1)} \times s\mathbf{Set}^+_{/(Z_2,\mathcal{E}_2)} \longrightarrow s\mathbf{Set}^+_{/(Z_1\times Z_2,\mathcal{E}_1\times\mathcal{E}_2)}$$

is left Quillen. Consequently, the bifunctors

$$\begin{aligned} \mathrm{Map}_Z(-,-) &: s\mathbf{Set}^{+\,op}_{/(Z,\mathcal{E})} \times s\mathbf{Set}^+_{/(Z,\mathcal{E})} \longrightarrow s\mathbf{Set}_{Quillen} \\ \mathrm{Fun}_Z(-,-) &: s\mathbf{Set}^{+\,op}_{/(Z,\mathcal{E})} \times s\mathbf{Set}^+_{/(Z,\mathcal{E})} \longrightarrow s\mathbf{Set}_{Joyal} \end{aligned}$$

are right Quillen, so $s\mathbf{Set}^+_{/(Z,E)}$ is both a $s\mathbf{Set}_{Quillen}$-enriched model category (with respect to Map_Z) and $s\mathbf{Set}_{Joyal}$-enriched model category (with respect to Fun_Z).

2.22. **Remark.** As explained in [17, Digression 1.2.13], by Proposition 2.21 the full subcategory of $s\mathbf{Set}^+_{/(Z,\mathcal{E})}$ spanned by the fibrant objects is an example of an ∞-cosmos [17, Definition 1.2.1].

Finally, we explain how the formalism of marked simplicial sets can be used to extract the pushforward functors implicitly defined by a cocartesian fibration. First, we need a lemma.

2.23. **Lemma.** *For $n>0$, the inclusion $i_n : \Delta^{n-1} \cong \Delta^{\{0\}} \star \Delta^{\{2,\dots,n\}} \longrightarrow {}_\natural\Delta^n$ is left marked anodyne. Consequently, for a cocartesian fibration $C \longrightarrow S$, the map*

$$\mathrm{Fun}({}_\natural\Delta^n, {}_\natural C) \longrightarrow \mathrm{Fun}(\Delta^{n-1}, C) \times_{\mathrm{Fun}(\Delta^{n-1},C)} \mathrm{Fun}(\Delta^n, S)$$

induced by i_n is a trivial Kan fibration.

Proof. We proceed by induction on n, the base case $n=1$ being the left marked anodyne map $\Delta^{\{0\}} \longrightarrow {}_\natural\Delta^1 = (\Delta^1)^\sharp$. Consider the commutative diagram

$$\begin{array}{ccc} \Delta^{\{0\}} \star \partial\Delta^{n-2} & \longrightarrow & \Delta^{\{0\}} \star \Delta^{\{2,\dots,n\}} \\ \big\downarrow \cup\, i_{n-1} & & \big\downarrow \quad \searrow i_n \\ (\Delta^{\{0\}} \star \Lambda^{n-1}_0, \mathcal{E}) & \longrightarrow & {}_\natural\Lambda^n_0 \\ & & \big\downarrow \\ & & {}_\natural\Delta^n \end{array}$$

where $\mathcal{E}$ is the collection of edges $\{0,i\}$, $0<i\le n$ (and the degenerate edges). The square is a pushout, and by the inductive hypothesis, the lefthand vertical map is left marked anodyne. We deduce that i_n is left marked anodyne. The second statement now follows because the lifting problem

$$\begin{array}{ccc} A & \longrightarrow & \mathrm{Fun}({}_\natural\Delta^n, {}_\natural C) \\ \big\downarrow & \nearrow & \big\downarrow \\ B & \longrightarrow & \mathrm{Fun}(\Delta^{n-1}, C) \times_{\mathrm{Fun}(\Delta^{n-1},C)} \mathrm{Fun}(\Delta^n, S) \end{array}$$

transposes to

$$\begin{array}{ccc} A \times {}_\natural\Delta^n \displaystyle\bigcup_{A\times\Delta^{n-1}} B\times\Delta^{n-1} & \longrightarrow & {}_\natural C \\ \big\downarrow & \nearrow & \big\downarrow \\ B \times {}_\natural\Delta^n & \longrightarrow & S \end{array}$$

and the lefthand vertical map is left marked anodyne for any cofibration $A \longrightarrow B$ by [10, Proposition 3.1.2.3]. □

The main case of interest in Lemma 2.23 is when $n = 1$, which shows that

$$\mathcal{O}^{cocart}(C) \longrightarrow C \times_S \mathcal{O}(S)$$

is a trivial Kan fibration. Let

$$P : C \times_S \mathcal{O}(S) \longrightarrow \mathcal{O}^{cocart}(C)$$

be a section that fixes the inclusion $C \subset \mathcal{O}^{cocart}(C)$ (for this, note that $C \subset C \times_S \mathcal{O}(S)$ is a cofibration as it is a monomorphism of simplicial sets). Then we say that P or the further composite $P' = \mathrm{ev}_1 \circ P$ is a *cocartesian pushforward* for $C \longrightarrow S$. Given an edge α of S, $P'_\alpha : C_s \longrightarrow C_t$ is the pushforward functor $\alpha_!$ determined under the equivalence $\mathbf{Cat}^{cocart}_{\infty/S} \simeq \mathrm{Fun}(S, \mathbf{Cat}_\infty)$.

Functoriality in the base. Let $\pi : X \longrightarrow Z$ be a map of simplicial sets. Then the pullback functor $\pi^* : s\mathbf{Set}_{/Z} \longrightarrow s\mathbf{Set}_{/X}$ admits a left adjoint $\pi_!$, given by postcomposing with π. In addition, since $s\mathbf{Set}$ is a topos, π^* also admits a right adjoint π_*, which may be thought of as the functor of relative sections because $\mathrm{Hom}_{/X}(A, \pi_*(B)) \cong \mathrm{Hom}_{/Z}(A \times_X Z, B)$.

Now supposing that π is a map of marked simplicial sets, π^*, $\pi_!$, and π_* extend to functors of marked simplicial sets over X or Y in an evident manner. We then seek conditions under which the adjunctions $\pi_! \dashv \pi^*$ and $\pi^* \dashv \pi_*$ are Quillen with respect to the cocartesian model structures. To this end, we have the following theorem of Lurie:

2.24. **Theorem** ([12, Theorem B.4.2])**.** *Let*

$$(Z, \mathcal{E}) \xleftarrow{\pi} (X, \mathcal{F}) \xrightarrow{\rho} (X', \mathcal{F}')$$

be a span of marked simplicial sets such that Z, X, X' are ∞-categories and the collections of markings contain all the equivalences.

(i) The adjunction

$$\rho_! \colon s\mathbf{Set}^+_{/(X,\mathcal{F})} \rightleftarrows s\mathbf{Set}^+_{/(X',\mathcal{F}')} : \rho^*$$

is Quillen with respect to the cocartesian model structures.

(ii) Further suppose that

(1) For every object $x \in X$ and marked edge $f : z \to \pi(x)$ in Z, there exists a locally π-cartesian edge $x_0 \to x$ in X lifting f.

(2) π is a flat categorical fibration.

(3) $\mathcal{E}$ and $\mathcal{F}$ are closed under composition.

(4) Suppose given a commutative diagram

$$\begin{array}{ccccc} & & x_1 & & \\ & \overset{f}{\nearrow} & & \overset{g}{\searrow} & \\ x_0 & & \xrightarrow{\quad h \quad} & & x_2 \end{array}$$

in X where g is locally π-cartesian, $\pi(g)$ is marked, and $\pi(f)$ is an equivalence. Then f is marked if and only if h is marked. (Note in particular that, taking f to be an identity morphism, every locally π-cartesian edge lying over a marked edge is itself marked.)

Then the adjunction

$$\pi^* \colon s\mathbf{Set}^+_{/(X,\mathcal{F})} \rightleftarrows s\mathbf{Set}^+_{/(Z,\mathcal{E})} : \pi_*$$

is Quillen with respect to the cocartesian model structures.

We formulated Theorem 2.24 as a theorem concerning a span $Z \xleftarrow{\pi} X \xrightarrow{\rho} X'$ because in applications we will typically be interested in the composite Quillen adjunction

$$\rho_! \pi^* \colon s\mathbf{Set}^+_{/(Z,\mathcal{E})} \rightleftarrows s\mathbf{Set}^+_{/(X',\mathcal{F}')} : \pi_* \rho^*.$$

Here are two examples.

2.25. **Example** (Pairing cartesian and cocartesian fibrations)**.** Let $\pi : X \longrightarrow Z$ be a cartesian fibration. Then the span

$$Z^\sharp \xleftarrow{\pi} X^\natural \xrightarrow{\pi} Z^\sharp$$

satisfies the hypotheses of Theorem 2.24. Now given a cocartesian fibration $Y \longrightarrow Z$, define

$$\widetilde{\mathrm{Fun}}_Z(X,Y) := (\pi_* \pi^*)({}_\natural Y \to Z^\sharp).$$

Then the fiber of $\widetilde{\mathrm{Fun}}_Z(X,Y)$ over an object $z \in Z$ is $\mathrm{Fun}(X_z, Y_z)$, and given a morphism $\alpha : z_0 \longrightarrow z_1$, the pushforward functor

$$\alpha_! : \mathrm{Fun}(X_{z_0}, Y_{z_0}) \longrightarrow \mathrm{Fun}(X_{z_1}, Y_{z_1})$$

is given by precomposition in the source and postcomposition in the target. Note how this example highlights the relevance of condition (1) in Theorem 2.24(ii).

2.26. **Example** (Right Kan extension)**.** Let $f : Y \longrightarrow Z$ be a functor. We can apply Theorem 2.24 to perform the operation of right Kan extension at the level of cocartesian fibrations. Consider the span

$$Z^\sharp \xleftarrow{\mathrm{ev}_0} (\mathcal{O}(Z) \times_{Z,f} Y)^\sharp \xrightarrow{\mathrm{pr}_Y} Y^\sharp.$$

Then the conditions of Theorem 2.24 are satisfied, so we obtain a Quillen adjunction

$$(\mathrm{pr}_Y)_! (\mathrm{ev}_0)^* \colon s\mathbf{Set}^+_{/Z} \rightleftarrows s\mathbf{Set}^+_{/Y} : (\mathrm{ev}_0)_* (\mathrm{pr}_Y)^*.$$

In addition, the map $C \times_Z Y^\sharp \longrightarrow C \times_Z \mathcal{O}(Z)^\sharp \times_Z Y^\sharp$ induced by the identity section $\iota : Z \longrightarrow \mathcal{O}(Z)$ is a cocartesian equivalence in $s\mathbf{Set}^+_{/Y}$ for $C \longrightarrow Z$ *fibrant* in $s\mathbf{Set}^+_{/Z}$, by [3, Lemma 9.8]. Consequently, the induced adjunction of ∞-categories

$$(\mathrm{pr}_Y)_! (\mathrm{ev}_0)^* \colon \mathbf{Cat}^{cocart}_{\infty/Z} \rightleftarrows \mathbf{Cat}^{cocart}_{\infty/Y} : (\mathrm{ev}_0)_* (\mathrm{pr}_Y)^*$$

is equivalent to

$$f^* \colon \mathrm{Fun}(Z, \mathbf{Cat}_\infty) \rightleftarrows \mathrm{Fun}(Y, \mathbf{Cat}_\infty) : f_*$$

under the straightening/unstraightening equivalence (which is natural with respect to pullback).

Note that as a special case, if $Z = \Delta^0$ we recover the formula $\mathrm{Fun}_Y(Y^\sharp, {}_\natural C) \simeq \varprojlim F_C$ of [10, Corollary 3.3.3.2] (where $C \longrightarrow Y$ is a cocartesian fibration and $F_C : Y \longrightarrow \mathbf{Cat}_\infty$ the corresponding functor). Indeed, this construction of the right Kan extension of a cocartesian fibration is suggested by that result and the pointwise formula for a right Kan extension.

Finally, we will use the following two observations concerning the interaction of Theorem 2.24 with compositions and homotopy equivalences of spans (which we also recorded in [5]).

2.27. **Lemma.** *Suppose we have spans of marked simplicial sets*

$$X_0 \xleftarrow{\pi_0} Z_0 \xrightarrow{\rho_0} X_1$$

and

$$X_1 \xleftarrow{\pi_1} Z_1 \xrightarrow{\rho_1} X_2$$

which each satisfy the hypotheses of Theorem 2.24. Then the span

$$Z_0 \xleftarrow{\mathrm{pr}_0} Z_0 \times_{X_1} Z_1 \xrightarrow{\mathrm{pr}_1} Z_1$$

also satisfies the hypothesis of Theorem 2.24.[14] *Consequently, we obtain a Quillen adjunction*

$$(\rho_1 \circ \mathrm{pr}_1)_! (\pi_0 \circ \mathrm{pr}_0)^* \colon s\mathbf{Set}^+_{/X_0} \rightleftarrows s\mathbf{Set}^+_{X_2} : (\pi_0 \circ \mathrm{pr}_0)_* (\rho_1 \circ \mathrm{pr}_1)^*,$$

which is the composite of the Quillen adjunction from $s\mathbf{Set}^+_{/X_0}$ to $s\mathbf{Set}^+_{/X_1}$ with the one from $s\mathbf{Set}^+_{/X_1}$ to $s\mathbf{Set}^+_{/X_2}$.

Proof. The assertion that the span satisfies the hypotheses of Theorem 2.24 is by inspection. The other assertion that the Quillen adjunction factors as a composite follows from the base-change isomorphism $\rho_0^* \pi_{1,*} \cong \mathrm{pr}_{0,*} \circ \mathrm{pr}_1^*$. □

[14] However, one should beware that the "long" span

$$X_0 \longleftarrow Z_0 \times_{X_1} Z_1 \longrightarrow X_2$$

may fail to satisfy the hypotheses of Theorem 2.24, because the composition of locally cartesian fibrations may fail to again be locally cartesian; this explains the roundabout formulation of the statement.

2.28. **Lemma.** *Suppose a morphism of spans of marked simplicial sets*

$$\begin{array}{ccccc} & & Z & & \\ & {}^{\pi}\swarrow & \downarrow{\scriptstyle f} & \searrow^{\rho} & \\ X & \xleftarrow[\pi']{} & Z' & \xrightarrow[\rho']{} & X' \end{array}$$

where $\rho_! \pi^*$ and $(\rho')_!(\pi')^*$ are left Quillen with respect to the cocartesian model structures on X and X'. Suppose moreover that f is a homotopy equivalence in $s\mathbf{Set}^+_{/X'}$, so that there exists a homotopy inverse g and homotopies

$$h\colon \mathrm{id} \simeq g \circ f \quad \textit{and} \quad k\colon \mathrm{id} \simeq f \circ g.$$

Then the natural transformation $\rho_! \pi^* \longrightarrow (\rho')_!(\pi')^*$ induced by f is a cocartesian equivalence on all objects, and, consequently, the adjoint natural transformation $(\pi')_*(\rho')^* \longrightarrow \pi_* \rho^*$ is a cocartesian equivalence on all fibrant objects.

Proof. The homotopies h and k pull back to show that for all $X \longrightarrow C$, the map

$$\mathrm{id}_X \times_C f\colon X \times_C K \longrightarrow X \times_C L$$

is a homotopy equivalence with inverse $\mathrm{id}_X \times_C g$. The last statement now follows from [8, Corollary 1.4.4(b)]. $\square$

Parametrized fibers. In this brief subsection, we record notation for the S-fibers of an S-functor.

2.29. **Notation.** Given an S-category $\pi : D \longrightarrow S$ and an object $x \in D$, define

$$\mathcal{O}_{x\to}(D) := \{x\} \times_D \mathcal{O}(D).$$

For the full subcategory of cocartesian edges $\mathcal{O}^{cocart}(D) \subset \mathcal{O}(D)$, also define

$$\underline{x} := \{x\} \times_D \mathcal{O}^{cocart}(D).$$

Given an S-functor $\phi : C \longrightarrow D$, define

$$C_{\underline{x}} := \underline{x} \times_{D,\phi} C.$$

Note that by definition, the objects of $\underline{x}$ are π-cocartesian edges in D with source x. Then by the right cancellative property of π-cocartesian edges [10, Lemma 2.4.2.7], the morphisms in $\underline{x}$ are 2-simplices of cocartesian edges with source x, hence $\underline{x}$ is an S-space (via the map $\mathrm{ev}_1 : \underline{x} \longrightarrow S$). In fact, by Lemma 12.10, $\mathrm{ev}_1 : \underline{x} \longrightarrow S^{\pi x/}$ is a trivial fibration, so we may think of $\underline{x}$ as an 'S-point' of D.

In view of this, we will also regard $C_{\underline{x}}$ as a $S^{\pi x/}$-category (and we will sometimes be cavalier about the distinction between $\underline{x}$ and $S^{\pi x/}$). Note however, that the functor $\underline{x} \longrightarrow D$ is canonical in our setup, whereas we need to make a choice of cocartesian pushforward to choose a S-functor $S^{\pi x/} \longrightarrow D$ that selects $x \in D$.

3. Functor categories

Let S be an ∞-category. Then $\mathrm{Fun}(S, \mathbf{Cat}_\infty)$ is cartesian closed, so it possesses an internal hom. As a basic application of Theorem 2.24, we will define this internal hom at the level of cocartesian fibrations over S.

3.1. **Proposition.** *Let $C \longrightarrow S$ be a cocartesian fibration. Let $\mathrm{ev}_0, \mathrm{ev}_1 : \mathcal{O}(S) \times_S C \longrightarrow S$ denote the source and target maps. Then the functor*

$$(\mathrm{ev}_1)_!(\mathrm{ev}_0)^* : s\mathbf{Set}^+_{/S} \longrightarrow s\mathbf{Set}^+_{/\mathcal{O}(S)^\sharp \times_S {}^\natural C} \longrightarrow s\mathbf{Set}^+_{/S}$$

is left Quillen with respect to the cocartesian model structures.

Proof. We verify the hypotheses of Theorem 2.24 as applied to the span $S^\sharp \xleftarrow{\mathrm{ev}_0} \mathcal{O}(S)^\sharp \times_S {}^\natural C \xrightarrow{\mathrm{ev}_1} S^\sharp$. By [10, Corollary 2.4.7.12], ev_0 is a cartesian fibration and an edge e in $\mathcal{O}(S) \times_S C$ is ev_0-cartesian if and only if its projection to C is an equivalence. (1) thus holds. (2) holds since cartesian fibrations are flat categorical fibrations. (3) is obvious. (4) follows from the stability of cocartesian edges under equivalence. $\square$

3.2. **Definition.** In the statement of Proposition 3.1, let

$$\underline{\mathrm{Fun}}_S(C,-) := (\mathrm{ev}_0)_*(\mathrm{ev}_1)^* : s\mathbf{Set}^+_{/S} \longrightarrow s\mathbf{Set}^+_{/S}.$$

We will also write this as $\underline{\mathrm{Fun}}_S({}_\natural C,-)$ if we wish to emphasize the marking.

Proposition 3.1 implies that if $D \longrightarrow S$ is a cocartesian fibration, $\underline{\mathrm{Fun}}_S(C,D) \longrightarrow S$ is a cocartesian fibration. Unwinding the definitions, we see that an object of $\underline{\mathrm{Fun}}_S(C,D)$ over $s \in S$ is a $S^{s/}$-functor

$$S^{s/} \times_S C \longrightarrow S^{s/} \times_S D,$$

and a cocartesian edge of $\underline{\mathrm{Fun}}_S(C,D)$ over an edge $e : \Delta^1 \longrightarrow S$ is a $\Delta^1 \times_S \mathcal{O}(S)$-functor

$$\Delta^1 \times_S \mathcal{O}(S) \times_S C \longrightarrow \Delta^1 \times_S \mathcal{O}(S) \times_S D.$$

Our first goal is to prove that the construction $\underline{\mathrm{Fun}}_S(C,-)$ implements the internal hom at the level of underlying ∞-categories. To this end, we have the following lemma and proposition.

3.3. **Lemma.** *Let $\iota : S \longrightarrow \mathcal{O}(S)$ be the identity section and regard $\mathcal{O}(S)^\sharp$ as a marked simplicial set over S via the target map. Then*

(1) For every marked simplicial set $X \longrightarrow S$ and cartesian fibration $C \longrightarrow S$,

$$\mathrm{id}_X \times \iota \times \mathrm{id}_C : X \times_S C^\natural \longrightarrow X \times_S \mathcal{O}(S)^\sharp \times_S C^\natural$$

is a cocartesian equivalence in $s\mathbf{Set}^+_{/S}$.

(1′) For every marked simplicial set $X \longrightarrow S$ and cartesian fibration $C \longrightarrow S$,

$$\iota \times \mathrm{id}_C : X \times_S C^\natural \longrightarrow \mathrm{Fun}((\Delta^1)^\sharp, X) \times_S C^\natural$$

is a cocartesian equivalence in $s\mathbf{Set}^+_{/S}$, where the marked edges in $\mathrm{Fun}((\Delta^1)^\sharp, X)$ are the marked squares in X.

(2) For every marked simplicial set $X \longrightarrow S$ and cocartesian fibration $C \longrightarrow S$,

$$\mathrm{id}_C \times \iota \times \mathrm{id}_X : {}_\natural C \times_S X \longrightarrow {}_\natural C \times_S \mathcal{O}(S)^\sharp \times_S X$$

is a homotopy equivalence in $s\mathbf{Set}^+_{/S}$.

Proof. (1) Because $- \times_S C^\natural$ preserves cocartesian equivalences, we reduce to the case where $C = S$. By definition, $X \longrightarrow X \times_S \mathcal{O}(S)^\sharp$ is a cocartesian equivalence if and only if for every cocartesian fibration $Z \longrightarrow S$, $\mathrm{Map}^\sharp_S(X \times_S \mathcal{O}(S)^\sharp, {}_\natural Z) \longrightarrow \mathrm{Map}^\sharp_S(X, {}_\natural Z)$ is a trivial Kan fibration. In other words, for every monomorphism of simplicial sets $A \longrightarrow B$ and cocartesian fibration $Z \longrightarrow S$, we need to provide a lift in the following commutative square

$$\begin{array}{ccc} B^\sharp \times X \bigsqcup_{A^\sharp \times X} (A^\sharp \times X) \times_S \mathcal{O}(S)^\sharp & \xrightarrow{\phi} & {}_\natural Z \\ \downarrow & \nearrow & \downarrow \\ (B^\sharp \times X) \times_S \mathcal{O}(S)^\sharp & \longrightarrow & S^\sharp \end{array}$$

Define $h_0 : \mathcal{O}(S)^\sharp \times (\Delta^1)^\sharp \longrightarrow \mathcal{O}(S)^\sharp$ to be the adjoint to the map $\mathcal{O}(S)^\sharp \longrightarrow \mathcal{O}(\mathcal{O}(S))^\sharp$ obtained by precomposing by the map of posets $\Delta^1 \times \Delta^1 \longrightarrow \Delta^1$ which sends $(1,1)$ to 1 and the other vertices to 0. Precomposing ϕ by $\mathrm{id}_{A^\sharp \times X} \times h_0$, define a homotopy

$$h : (A^\sharp \times X) \times_S \mathcal{O}(S)^\sharp \times (\Delta^1)^\sharp \longrightarrow {}_\natural Z$$

from $\phi|_{A^\sharp \times X} \circ \mathrm{pr}_{A^\sharp \times X}$ to $\phi|_{(A^\sharp \times X) \times_S \mathcal{O}(S)^\sharp}$. Using h and $\phi|_{B^\sharp \times X}$, define a map

$$\psi : B^\sharp \times X \bigsqcup_{A^\sharp \times X} (A^\sharp \times X) \times_S \mathcal{O}(S)^\sharp \longrightarrow \mathrm{Fun}((\Delta^1)^\sharp, {}_\natural Z)$$

such that $\psi|_{B^\sharp \times X}$ is adjoint to $\phi|_{B^\sharp \times X} \circ \mathrm{pr}_{B^\sharp \times X}$ and $\psi|_{(A^\sharp \times X)\times_S \mathcal{O}(S)^\sharp}$ is adjoint to h. Then we may factor the above square through the trivial fibration $\mathrm{Fun}((\Delta^1)^\sharp, {}_\natural Z) \longrightarrow {}_\natural Z \times_S \mathcal{O}(S)^\sharp$ to obtain the commutative rectangle

$$\begin{array}{ccccc} B^\sharp \times X \coprod_{A^\sharp \times X} (A^\sharp \times X) \times_S \mathcal{O}(S)^\sharp & \xrightarrow{\psi} & \mathrm{Fun}((\Delta^1)^\sharp, {}_\natural Z) & \xrightarrow{e_1} & {}_\natural Z \\ \downarrow & \overset{\widetilde{\psi}}{\nearrow} & \downarrow \simeq & & \downarrow \\ (B^\sharp \times X) \times_S \mathcal{O}(S)^\sharp & \xrightarrow[\phi|_{B^\sharp \times X} \times \mathrm{id}]{} & {}_\natural Z \times_S \mathcal{O}(S)^\sharp & \xrightarrow{e_1} & S^\sharp. \end{array}$$

The dotted lift $\widetilde{\psi}$ exists, and $e_1 \circ \widetilde{\psi}$ is our desired lift.

(1') Repeat the argument of (1) with $\mathrm{Fun}((\Delta^1)^\sharp, X)$ in place of $\mathcal{O}(S)^\sharp$.

(2) Let $p : C \longrightarrow S$ denote the structure map and let P be a lift in the commutative square

$$\begin{array}{ccc} {}_\natural C & \xrightarrow{\iota_C} & \mathrm{Fun}((\Delta^1)^\sharp, {}_\natural C) \\ \downarrow & \overset{P}{\nearrow} & \simeq \downarrow (e_0, \mathcal{O}(p)) \\ {}_\natural C \times_S \mathcal{O}(S)^\sharp & \xrightarrow{=} & {}_\natural C \times_S \mathcal{O}(S)^\sharp. \end{array}$$

Let

$$g = (e_1 \times \mathrm{id}_X) \circ (P \times \mathrm{id}_X) : {}_\natural C \times_S \mathcal{O}(S)^\sharp \times_S X \longrightarrow {}_\natural C \times_S X$$

and note that g is a map over S. We claim that g is a marked homotopy inverse of $f = \mathrm{id}_C \times \iota \times \mathrm{id}_X$. By construction, $g \circ f = \mathrm{id}$. For the other direction, define

$$h_0 : \mathrm{Fun}((\Delta^1)^\sharp, {}_\natural C) \times (\Delta^1)^\sharp \longrightarrow \mathrm{Fun}((\Delta^1)^\sharp, {}_\natural C)$$

as the adjoint of the map $\mathrm{Fun}((\Delta^1)^\sharp, {}_\natural C) \longrightarrow \mathrm{Fun}((\Delta^1 \times \Delta^1)^\sharp, {}_\natural C)$ obtained by precomposing by the map of posets $\Delta^1 \times \Delta^1 \longrightarrow \Delta^1$ which sends $(0,0)$ to 0 and the other vertices to 1. Define

$$h : {}_\natural C \times_S \mathcal{O}(S)^\sharp \times_S X \times (\Delta^1)^\sharp \longrightarrow {}_\natural C \times_S \mathcal{O}(S)^\sharp \times_S X$$

as the composite $((e_0, \mathcal{O}(p)) \times X) \circ (h_0 \times X) \circ (P \times \mathrm{id}_{X \times (\Delta^1)^\sharp})$. Then h is a homotopy over S from id to $f \circ g$.

□

3.4. **Proposition.** *Let $C, C', D \longrightarrow S$ be cocartesian fibrations and let $F : C \longrightarrow C'$ be a monomorphism of cocartesian fibrations over S (so preserving cocartesian edges). For all marked simplicial sets Y over S, the map*

$$\mathrm{Fun}_S({}_\natural D, \underline{\mathrm{Fun}}_S({}_\natural C', Y)) \longrightarrow \mathrm{Fun}_S({}_\natural D \times_S {}_\natural C', Y) \times_{\mathrm{Fun}_S({}_\natural D \times_S {}_\natural C, Y)} \mathrm{Fun}_S({}_\natural D, \underline{\mathrm{Fun}}_S({}_\natural C, Y))$$

which precomposes by F is a trivial Kan fibration.

Proof. From the defining adjunction, for all $X, Y \in s\mathbf{Set}^+_{/S}$ we have a natural isomorphism

$$\mathrm{Fun}_S(X, \underline{\mathrm{Fun}}_S({}_\natural C, Y)) \cong \mathrm{Fun}_S(X \times_S \mathcal{O}(S)^\sharp \times_S {}_\natural C, Y)$$

of simplicial sets. Since $\mathrm{Fun}_S(-,-)$ is a right Quillen bifunctor, the assertion reduces to showing that

$${}_\natural D \times_S {}_\natural C' \coprod_{{}_\natural D \times_S {}_\natural C} {}_\natural D \times_S \mathcal{O}(S)^\sharp \times_S {}_\natural C \longrightarrow {}_\natural D \times_S \mathcal{O}(S)^\sharp \times_S {}_\natural C'$$

is a trivial cofibration in $s\mathbf{Set}^+_{/S}$, which follows from Lemma 3.3(2). □

In Proposition 3.4, letting $C = \emptyset$ and $Y = {}_\natural E$ for another cocartesian fibration $E \longrightarrow S$, we deduce that $\underline{\mathrm{Fun}}_S(C', -)$ is right adjoint to $C' \times_S -$ as an endofunctor of $\mathrm{Fun}(S, \mathbf{Cat}_\infty)$. Further setting $D = S$, we deduce that the category of cocartesian sections of $\underline{\mathrm{Fun}}_S({}_\natural C, {}_\natural E)$ is equivalent to $\mathrm{Fun}_S({}_\natural C, {}_\natural E)$. We will employ the following notation to explicitly track objects under this correspondence.

3.5. **Notation.** Given a map $f : {}_\natural C \longrightarrow {}_\natural E$, let σ_f denote the cocartesian section $S^\sharp \longrightarrow \underline{\mathrm{Fun}}_S({}_\natural C, {}_\natural E)$ given by adjointing the map $\mathcal{O}(S)^\sharp \times_S {}_\natural C \xrightarrow{\mathrm{pr}_C} {}_\natural C \xrightarrow{f} {}_\natural E$.

We next study varying the second variable in the construction $\underline{\mathrm{Fun}}_S(-,-)$.

3.6. **Lemma.** *Let $C \longrightarrow D$ be a fibration of marked simplicial sets over S.*

(1) Let $K \longrightarrow S$ be a cocartesian fibration. Then
$$\underline{\mathrm{Fun}}_S({}_\natural K, C) \longrightarrow \underline{\mathrm{Fun}}_S({}_\natural K, D) \times_D C$$
is a fibration in $s\mathbf{Set}^+_{/S}$.

(2) The map
$$\underline{\mathrm{Fun}}_S(S^\sharp, C) \longrightarrow \underline{\mathrm{Fun}}_S(S^\sharp, D) \times_D C$$
is a trivial fibration in $s\mathbf{Set}^+_{/S}$.

Proof. Let $i : A \longrightarrow B$ be a map of marked simplicial sets. For (1), we use that if i is a trivial cofibration, then
$$B \coprod_A A \times_S \mathcal{O}(S)^\sharp \times_S {}_\natural K \longrightarrow B \times_S \mathcal{O}(S) \times_S {}_\natural K$$
is a trivial cofibration, which follows from Proposition 3.1. For (2), we use that if i is a cofibration, then
$$B \coprod_A A \times_S \mathcal{O}(S)^\sharp \longrightarrow B \times_S \mathcal{O}(S)$$
is a trivial cofibration, which follows from Lemma 3.3(1). □

The following proposition indicates that we can promote the conclusion $\underline{\mathrm{Fun}}_S(S, -) \simeq \mathrm{id}$ (as an endofunctor of $\mathrm{Fun}(S, \mathbf{Cat}_\infty)$) of Proposition 3.4 to the level of cocartesian model structures. It will not be used in the sequel and is included only for illustrative purposes.

3.7. **Proposition.** *The Quillen adjunction*
$$- \times_S \mathcal{O}(S)^\sharp : s\mathbf{Set}^+_{/S} \rightleftarrows s\mathbf{Set}^+_{/S} : \underline{\mathrm{Fun}}_S(S^\sharp, -)$$
is a Quillen equivalence.

Proof. We first check that for every cocartesian fibration $C \longrightarrow S$, the counit map
$$\underline{\mathrm{Fun}}_S(S^\sharp, {}_\natural C) \times_S \mathcal{O}(S)^\sharp \longrightarrow {}_\natural C$$
is a cocartesian equivalence. By Lemma 3.3(1), it suffices to show that
$$\underline{\mathrm{Fun}}_S(S^\sharp, {}_\natural C) \longrightarrow {}_\natural C$$
is a trivial marked fibration, which follows from Lemma 3.6(2) (taking $D = S$). We now complete the proof by checking that $- \times_S \mathcal{O}(S)^\sharp$ reflects cocartesian equivalences: i.e., given the commutative square
$$\begin{array}{ccc} A & \longrightarrow & B \\ \downarrow & & \downarrow \\ A \times_S \mathcal{O}(S)^\sharp & \longrightarrow & B \times_S \mathcal{O}(S)^\sharp. \end{array}$$
if the lower horizontal map is a cocartesian equivalence over S (with respect to the target map) then the upper horizontal map is a cocartesian equivalence over S. But the vertical maps are cocartesian equivalences by Lemma 3.3(1). □

The construction $\underline{\mathrm{Fun}}_S(-, -)$ does not make homotopical sense when the first variable is not fibrant, so it does not yield a Quillen bifunctor. Nevertheless, we can say the following about varying the first variable.

3.8. **Proposition.** *Let K, L, and C be fibrant marked simplicial sets over S, let $f : K \longrightarrow L$ be a map and let*
$$f^* : \underline{\mathrm{Fun}}_S(L, C) \longrightarrow \underline{\mathrm{Fun}}_S(K, C)$$
denote the induced map.

(1) Suppose that f is a cocartesian equivalence over S. Then f^* is a cocartesian equivalence over S.

(2) Suppose that f is a cofibration. Then f^* is a fibration in $s\mathbf{Set}^+_{/S}$.

Proof. (1): It suffices to check that for all $s \in S$, f^* induces a categorical equivalence between the fibers over s, i.e. that

$$\mathrm{Fun}_S((S^{s/})^\sharp \times_S L, C) \longrightarrow \mathrm{Fun}_S((S^{s/})^\sharp \times_S K, C)$$

is a categorical equivalence. Our assumption implies that $(S^{s/})^\sharp \times_S K \longrightarrow (S^{s/})^\sharp \times_S L$ is a cocartesian equivalence over S, so this holds.

(2): For any trivial cofibration $A \longrightarrow B$ in $s\mathbf{Set}^+_S$, we need to check that

$$A \times_S \mathcal{O}(S) \times_S L \coprod_{A \times_S \mathcal{O}(S) \times_S K} B \times_S \mathcal{O}(S) \times_S K \longrightarrow B \times_S \mathcal{O}(S) \times_S L$$

is a trivial cofibration in $s\mathbf{Set}^+_{/S}$. By Proposition 3.1, $- \times_S \mathcal{O}(S) \times_S K$ preserves trivial cofibrations and ditto for L. The result then follows. □

A final word on notation: since $\underline{\mathrm{Fun}}_S(-,-)$ is only homotopically meaningful (and fibrant) when both variables are fibrant, we will henceforth cease to denote the markings on the variables.

S-categories of S-objects. For the convenience of the reader, we briefly review the construction and basic properties of the S-category of S-objects in an ∞-category C. This is a construction, at the level of marked simplicial sets, of the right adjoint to the Grothendieck construction functor[15]

$$\mathrm{Gr}_U : \mathbf{Cat}^{cocart}_{\infty/S} \longrightarrow \mathbf{Cat}_\infty, \quad (C \longrightarrow S) \mapsto C.$$

This material is originally due to Denis Nardin in [3, §7].

3.9. **Construction** ([3, Definition 7.4])**.** The span

$$S^\sharp \xleftarrow{\mathrm{ev}_0} \mathcal{O}(S)^\natural \xrightarrow{\rho} \Delta^0$$

defines a right Quillen functor $(\mathrm{ev}_0)_* \rho^* : s\mathbf{Set}^+ \longrightarrow s\mathbf{Set}^+_{/S}$, which sends an ∞-category E to $\widetilde{\mathrm{Fun}}_S(\mathcal{O}(S), E \times S)$ (cf. Example 2.25). This is the *S-category of objects in E*, which we will denote by $\underline{E}_S$.

The next proposition shows that the functor $E \mapsto \underline{E}_S$ indeed implements the right adjoint to Gr_U.

3.10. **Proposition.** *Suppose C a S-category and E an ∞-category. Then we have an equivalence*

$$\psi : \mathrm{Fun}_S(C, \underline{E}_S) \xrightarrow{\simeq} \mathrm{Fun}(C, E)$$

Proof. Consider the commutative diagram

$$\begin{array}{ccccc} C^\sim & \longrightarrow & \mathcal{O}(S)^\natural & \longrightarrow & \Delta^0 . \\ \downarrow & & \downarrow & & \\ {}_\natural C & \longrightarrow & S^\sharp & & \\ \downarrow & & & & \\ \Delta^0 & & & & \end{array}$$

Given an ∞-category E, travelling along the outer span (i.e., pulling back and then pushing forward) yields $\mathrm{Fun}(C, E)$, travelling along the two inner spans yields $\mathrm{Fun}_S(C, \underline{E}_S)$, and the comparison functor ψ is induced by the map $\iota : C^\sim \longrightarrow {}_\natural C \times_S \mathcal{O}(S)^\natural$. By [3, Proposition 6.2], ι is a homotopy equivalence in $s\mathbf{Set}^+_{/S}$. Therefore, combining Lemma 2.27 and Lemma 2.28, we deduce the claim. □

3.11. **Notation.** Given a S-functor $p : C \longrightarrow \underline{E}_S$, let $p^\dagger : C \longrightarrow E$ denote the corresponding functor under the equivalence of Proposition 3.10.

[15] We write Gr_U to distinguish from Notation 2.6.

3.12. **Example.** Let $E = \mathbf{Spc}$ or $\mathbf{Cat}_\infty$. Then $\underline{\mathbf{Spc}}_S$ resp. $\underline{\mathbf{Cat}}_{\infty,S}$ is the S-category of S-spaces resp. S-categories. In particular, suppose $E = \mathbf{Spc}$ and $S = \mathbf{O}_G^{op}$. Then we also call $\underline{\mathbf{Spc}}_{\mathbf{O}_G^{op}}$ the G-∞-category of G-spaces. Note that the fiber of this cocartesian fibration over a transitive G-set G/H is equivalent to the ∞-category of H-spaces $\mathrm{Fun}(\mathbf{O}_H^{op}, \mathbf{Spc})$, and the pushforward functors are given by restriction along a subgroup and conjugation.

3.13. **Remark.** Let C be an S-category and $\pi : X \longrightarrow C$ a left fibration. Then π straightens to a functor $F : C \longrightarrow \mathbf{Spc}$, which under the equivalence of Proposition 3.10 corresponds to a S-functor $F' : C \longrightarrow \underline{\mathbf{Spc}}_S$. We will say that π *S-straightens* to F'. Similarly, if π is a cocartesian fibration, then π S-straightens to a S-functor valued in $\underline{\mathbf{Cat}}_{\infty,S}$.

4. Join and slice

The join and slice constructions are at the heart of the ∞-categorical approach to limits and colimits. In this section, we introduce relative join and slice constructions and explore their homotopical properties.

The S-join.

4.1. **Definition.** Let $\iota : S \times \partial\Delta^1 \hookrightarrow S \times \Delta^1$ be the inclusion. Define the *S-join* to be the functor

$$(- \star_S -) := \iota_* : s\mathbf{Set}_{/S\times\partial\Delta^1} \longrightarrow s\mathbf{Set}_{/S\times\Delta^1}.$$

Define the *marked S-join* to be the functor

$$(- \star_S -) := \iota_* : s\mathbf{Set}^+_{/S^\sharp\times(\partial\Delta^1)^\flat} \longrightarrow s\mathbf{Set}^+_{/S^\sharp\times(\Delta^1)^\flat}.$$

4.2. **Notation.** Given X, Y marked simplicial sets over S, we will usually refer to the structure maps to S by $\pi_1 : X \longrightarrow S$, $\pi_2 : Y \longrightarrow S$, and $\pi : X \star_S Y \longrightarrow S$. Explicitly, a $(i+j+1)$-simplex λ of $X \star_S Y$ is the data of simplices $\sigma : \Delta^i \longrightarrow X$, $\tau : \Delta^j \longrightarrow Y$, and $\lambda' : \Delta^i \star \Delta^j \longrightarrow S$ such that the diagram

$$\begin{array}{ccccc} \Delta^i & \longrightarrow & \Delta^i \star \Delta^j & \longleftarrow & \Delta^j \\ \downarrow{\scriptstyle \sigma} & & \downarrow{\scriptstyle \lambda'} & & \downarrow{\scriptstyle \tau} \\ X & \xrightarrow{\pi_1} & S & \xleftarrow{\pi_2} & Y \end{array}$$

commutes; we then have that $\lambda' = \pi \circ \lambda$. We will sometimes write $\lambda = (\sigma, \tau)$ so as to remember the data of the i-simplex of X and the j-simplex of Y in the notation. If given an n-simplex of $X \star_S Y$, we will indicate the decomposition of Δ^n given by the structure map to Δ^1 as $\Delta^{n_0} \star \Delta^{n_1}$ (with either side possibly empty).

4.3. **Proposition.** *Let $\iota : S \times \partial\Delta^1 \hookrightarrow S \times \Delta^1$ be the inclusion. Then*

(a) $\iota_* : s\mathbf{Set}_{/S\times\partial\Delta^1} \longrightarrow s\mathbf{Set}_{/S\times\Delta^1}$ is a right Quillen functor.
(b) $\iota_* : s\mathbf{Set}^+_{/S^\sharp\times(\partial\Delta^1)^\flat} \longrightarrow s\mathbf{Set}^+_{/S^\sharp\times(\Delta^1)^\flat}$ is a right Quillen functor.

Consequently, if X and Y are categorical resp. cocartesian fibrations over S, then $X \star_S Y$ is a categorical resp. cocartesian fibration over S, with the cocartesian edges given by those in X and Y.

Proof. For (b), we verify the hypotheses of Theorem 2.24(ii). All of the requirements are immediate except for (1) and (2).

(1): Let (s, i) be a vertex of $S^\sharp \times (\partial\Delta^1)^\flat$, $i = 0$ or 1. Let $f : (s', i') \longrightarrow (s, i)$ be a marked edge in $S^\sharp \times (\Delta^1)^\flat$. Then $i' = i$ and f viewed as an edge in $S^\sharp \times (\partial\Delta^1)^\flat$ is locally ι-cartesian.

(2): It is obvious that $\partial\Delta^1 \hookrightarrow \Delta^1$ is a flat categorical fibration, so by stability of flat categorical fibrations under base change, $S \times \partial\Delta^1 \hookrightarrow S \times \Delta^1$ is a flat categorical fibration.

(a) also follows from (2) by [12, Proposition B.4.5]. By (a), if X and Y are categorical fibrations over S, $X \star_S Y$ is a categorical fibration over $S \times \Delta^1$. The projection map $S \times \Delta^1 \longrightarrow S$ is a categorical fibration, so $X \star_S Y$ is also a categorical fibration over S. By (b), if X and Y are cocartesian fibrations over S, ${}_\natural X \star_S {}_\natural Y$ is fibrant in $s\mathbf{Set}^+_{/S^\sharp\times(\Delta^1)^\flat}$. Since $S^\sharp \times (\Delta^1)^\flat$ is marked as a cocartesian fibration over S, ${}_\natural X \star_S {}_\natural Y$ is marked as a cocartesian fibration over S. $\square$

We have the compatibility of the relative join with base change.

4.4. **Lemma.** *Let $f : T \longrightarrow S$ be a functor and let X and Y be (marked) simplicial sets over S. Then we have a canonical isomorphism*

$$(X \star_S Y) \times_S T \cong (X \times_S T) \star_T (Y \times_S T).$$

Proof. From the pullback square

$$\begin{array}{ccc} T \times \partial\Delta^1 & \xrightarrow{\iota_T} & T \times \Delta^1 \\ \downarrow{\scriptstyle f\times \mathrm{id}} & & \downarrow{\scriptstyle f\times \mathrm{id}} \\ S \times \partial\Delta^1 & \xrightarrow{\iota_S} & S \times \Delta^1 \end{array}$$

we obtain the base-change isomorphism $f^*(\iota_S)_* \cong (\iota_T)_* f^*$. □

In [10, §4.2.2], Lurie introduces the relative 'diamond' join operation $\diamond_S$, which we now recall. Given X and Y marked simplicial sets over S, define

$$X \diamond_S Y = X \sqcup_{X \times_S Y \times \{0\}} X \times_S Y \times (\Delta^1)^\flat \sqcup_{X \times_S Y \times \{1\}} Y.$$

There is a comparison map

$$\psi_{(X,Y)} : X \diamond_S Y \longrightarrow X \star_S Y = \iota_*(X, Y),$$

adjoint to the isomorphism $\iota^*(X \star_S Y) \cong (X, Y)$.

4.5. **Lemma.** *Let X be a marked simplicial set. Then $\psi_{(X,S)} : X \diamond_S S^\sharp \longrightarrow X \star_S S^\sharp$ is a cocartesian equivalence in $s\mathbf{Set}^+_{/S}$. Dually, if X is in addition fibrant, then $\psi_{(S,X)} : S^\sharp \diamond_S X \longrightarrow S^\sharp \star_S X$ is a cocartesian equivalence in $s\mathbf{Set}^+_{/S}$.*

Proof. We first address the map $\psi_{(X,S)}$. By left properness of the cocartesian model structure, the defining pushout for $X \diamond_S S^\sharp$ is a homotopy pushout. By Theorem 4.16,[16] $- \star_S S^\sharp$ preserves cocartesian equivalences. Therefore, choosing a fibrant replacement for X and using naturality of the comparison map $\psi_{(X,S)}$, we may reduce to the case that X is fibrant. Then we have to check that

$$\begin{array}{ccc} X \times \{1\} & \longrightarrow & X \times (\Delta^1)^\flat \\ \downarrow & & \downarrow \\ S^\sharp & \longrightarrow & X \star_S S^\sharp \end{array}$$

is a homotopy pushout square. Since this is a square of fibrant objects, this assertion can be checked fiberwise, in which case it reduces to the equivalence $X_s \diamond \Delta^0 \xrightarrow{\simeq} X^\triangleright$ of [10, Proposition 4.2.1.2].

The second statement concerning $\psi_{(S,X)}$ follows by the same type of argument, but without the reduction step. □

4.6. **Warning.** In general, $\psi_{(X,Y)}$ is not a cocartesian equivalence. As a counterexample, consider $S = \Delta^1$, $X = \{0\}$, and $Y = \{1\}$. Then $\psi_{(X,Y)}$ is the inclusion of $X \diamond_S Y \cong \Delta^{\{0\}} \sqcup \Delta^{\{1\}}$ into $X \star_S Y \cong \Delta^1$, which is not a cocartesian equivalence over Δ^1.

We will later need the following strengthening of the conclusion of Proposition 4.3.

4.7. **Proposition.** *(1) Let $C, C', D \longrightarrow S$ be inner fibrations and let $C, C' \longrightarrow D$ be functors over S. Then $C \star_D C' \longrightarrow S$ is an inner fibration.*

(2) Let $C, C', D \longrightarrow S$ be S-categories and let $C, C' \longrightarrow D$ be S-functors. Then $C \star_D C' \longrightarrow S$ is a S-category with cocartesian edges given by those in C or C', and $C \star_D C' \longrightarrow D$ is a S-functor.

[16] Note there is no circularity since Lemma 4.5 is only later referenced in this paper at the beginning of §9.

Proof. (1) Let $0 < k < n$. We need to solve the lifting problem

$$\begin{array}{ccc} \Lambda^n_k & \xrightarrow{\lambda_0} & C \star_D C' \\ \downarrow & \overset{\lambda}{\nearrow} & \downarrow \\ \Delta^n & \longrightarrow & S. \end{array}$$

Let $\overline{\lambda} : \Delta^n \longrightarrow D$ be a lift in the commutative square

$$\begin{array}{ccc} \Lambda^n_k & \longrightarrow & D \\ \downarrow & \overset{\overline{\lambda}}{\nearrow} & \downarrow \\ \Delta^n & \longrightarrow & S. \end{array}$$

Define λ using the data $(\lambda_0|_{\Delta^{n_0}}, \lambda_0|_{\Delta^{n_1}}, \overline{\lambda})$. Then λ is a valid lift.

(2) Consider $C \star_D C'$ as a marked simplicial set with marked edges those in ${}_\natural C$ or in ${}_\natural C'$. We need to solve the lifting problem

$$\begin{array}{ccc} {}_\natural\Lambda^n_0 & \xrightarrow{\lambda_0} & C \star_D C' \\ \downarrow & \overset{\lambda}{\nearrow} & \downarrow \\ {}_\natural\Delta^n & \longrightarrow & S. \end{array}$$

Let $\overline{\lambda} : \Delta^n \longrightarrow D$ be a lift in the commutative square

$$\begin{array}{ccc} {}_\natural\Lambda^n_0 & \longrightarrow & {}_\natural D \\ \downarrow & \overset{\overline{\lambda}}{\nearrow} & \downarrow \\ {}_\natural\Delta^n & \longrightarrow & S. \end{array}$$

Define λ using the data $(\lambda_0|_{\Delta^{n_0}}, \lambda_0|_{\Delta^{n_1}}, \overline{\lambda})$. Then λ is a valid lift. Finally, note that we may obviously lift against classes (3) and (4) of [10, Definition 3.1.1.1]. We conclude that $C \star_D C' \longrightarrow S$ is fibrant in $s\mathbf{Set}^+_{/S}$, hence an S-category with cocartesian edges as marked.

□

Since the S-join is defined as a right Kan extension, it is simple to map into. In the other direction, we can offer the following lemma.

4.8. **Lemma.** *Let C, C', D, and E be S-categories and let $C, C' \longrightarrow D$ be S-functors. Then*

$$\mathrm{Fun}_S(C \star_D C', E) \longrightarrow \mathrm{Fun}_S(C, E) \times \mathrm{Fun}_S(C', E)$$

is a bifibration [10, Definition 2.4.7.2]. *Consequently,*

$$\mathrm{Fun}_S(C \star_D C', E) \longrightarrow \mathrm{Fun}_S(C, E)$$

is a cartesian fibration with cartesian edges those sent to equivalences in $\mathrm{Fun}_S(C', E)$*, and*

$$\mathrm{Fun}_S(C \star_D C', E) \longrightarrow \mathrm{Fun}_S(C', E)$$

is a cocartesian fibration with cocartesian edges those sent to equivalences in $\mathrm{Fun}_S(C', E)$*.*

Proof. By inspection, the span

$$(\Delta^1)^\flat \xleftarrow{\pi} {}_\natural(C \star_D C') \xrightarrow{\pi'} S^\sharp$$

satisfies the hypotheses of Theorem 2.24. Therefore, $\pi_* \pi'^* ({}_\natural E \longrightarrow S)$ is a categorical fibration over Δ^1. The claim now follows from [10, Proposition 2.4.7.10], and the consequence from [10, Lemma 2.4.7.5] and its opposite. □

The Quillen adjunction between S-join and S-slice. Our next goal is to obtain a relative join and slice Quillen adjunction. To this end, we need a good understanding of the combinatorics of the relative join (Proposition 4.11). We prepare for the proof of that proposition with a few lemmas.

4.9. **Lemma.** *Let $i, l \geq -1$ and $j, k \geq 0$. Then the map*

$$\Delta^i \star \Delta^j \star \partial\Delta^k \star \Delta^l \coprod_{\Delta^j \star \partial\Delta^k \star \Delta^l} \Delta^{j+k+l+2} \hookrightarrow \Delta^{i+j+k+l+3}$$

is inner anodyne.

Proof. Let $f : \Delta^{j-1} \hookrightarrow \Delta^i \star \Delta^{j-1}$ and $g : \Lambda^{k+1}_0 \hookrightarrow \Delta^{k+1}$. The map in question is $f \star g \star \Delta^l$, so is inner anodyne by [10, Lemma 2.1.2.3]. □

By [10, Lemma 2.1.2.4], the join of a left anodyne map and an inclusion is left anodyne. We need a slight refinement of this result:

4.10. **Lemma.** *Let $f : A_0 \hookrightarrow A$ be a cofibration of simplicial sets.*

(1) Let $g : B_0 \hookrightarrow B$ be a right marked anodyne map between marked simplicial sets. Then

$$f^\flat \star g : A_0^\flat \star B \coprod_{A_0^\flat \star B_0} A^\flat \star B_0 \hookrightarrow A^\flat \star B$$

is a right marked anodyne map.

(2) Let $g : B_0 \hookrightarrow B$ be a left marked anodyne map between marked simplicial sets. Then

$$g \star f^\flat : B \star A_0^\flat \coprod_{B_0 \star A_0^\flat} B_0 \star A^\flat \hookrightarrow B \star A^\flat$$

is a left marked anodyne map.

Proof. We prove (1); the dual assertion (2) is proven by a similar argument. f lies in the weakly saturated closure of the inclusions $i_m : \partial\Delta^m \hookrightarrow \Delta^m$, so it suffices to check that $i_m^\flat \star g$ is right marked anodyne for the four classes of morphisms enumerated in [10, Definition 3.1.1.1]. For $g : (\Lambda^n_i)^\flat \hookrightarrow (\Delta^n)^\flat$, $0 < i < n$, $i_m^\flat \star g$ obtained from an inner anodyne map by marking common edges, so is marked right anodyne. For $g : \Lambda^{n\natural}_n \hookrightarrow \Delta^{n\natural}$, $i_m^\flat \star g$ is $\Lambda^{n+m+1\natural}_{n+m+1} \hookrightarrow \Delta^{n+m+1\natural}$, so $i_m^\flat \star g$ is marked right anodyne. For the remaining two classes, $i_m^\flat \star g$ is the identity because no markings are introduced when joining two marked simplicial sets. □

The following proposition reveals a basic asymmetry of the relative join, which is related to our choice of *cocartesian* fibrations to model functors.

4.11. **Proposition.** *Let K be a marked simplicial set over S.*

(1) For every marked left horn inclusion ${}_\natural\Lambda^n_0 \hookrightarrow {}_\natural\Delta^n$ over S, the induced map

$$K \star_S ({}_\natural\Lambda^n_0 \times_S \mathcal{O}(S)^\natural) \hookrightarrow K \star_S ({}_\natural\Delta^n \times_S \mathcal{O}(S)^\natural)$$

is left marked anodyne, where the pullbacks ${}_\natural\Lambda^n_0 \times_S \mathcal{O}(S)^\natural$ and ${}_\natural\Delta^n \times_S \mathcal{O}(S)^\natural$ are formed with respect to the source map e_0 and are regarded as marked simplicial sets over S via the target map e_1.

(1') For every left horn inclusion $\Lambda^n_0 \hookrightarrow \Delta^n$ over S, the induced map

$$\Delta^n \times_S \mathcal{O}(S) \coprod_{\Lambda^n_0 \times_S \mathcal{O}(S)} K \star_S (\Lambda^n_0 \times_S \mathcal{O}(S)) \hookrightarrow K \star_S (\Delta^n \times_S \mathcal{O}(S))$$

is an inner anodyne map.

(2) Let $e_0 : C \longrightarrow S$ be a cartesian fibration over S and let $e_1 : C \longrightarrow S$ be any map of simplicial sets. For every inner horn inclusion $\Lambda^n_k \hookrightarrow \Delta^n$, $0 < k < n$ over S, the induced map

$$K \star_S (\Lambda^n_k \times_S C) \hookrightarrow K \star_S (\Delta^n \times_S C)$$

is inner anodyne, where the pullbacks $\Lambda^n_k \times_S C$ and $\Delta^n \times_S C$ are formed with respect to e_0 and are regarded as simplicial sets over S via e_1.

(3) *For every marked right horn inclusion $\Lambda^{n\natural}_n \hookrightarrow \Delta^{n\natural}$ over S, the induced map*
$$K \star_S \Lambda^{n\natural}_n \hookrightarrow K \star_S \Delta^{n\natural}$$
is right marked anodyne.

Proof. Let I be the set of simplices of K endowed with a total order such that $\sigma < \sigma'$ if the dimension of σ is less than that of σ', where we view the empty set as a simplex of dimension -1. Let J be the set of epimorphisms $\chi : \Delta^j \twoheadrightarrow \Delta^{n-1}$ endowed with a total order such that $\chi < \chi'$ if the dimension of χ is less than that of χ'. Order $I \times J$ by $(\sigma, \chi) < (\sigma', \chi')$ if $\sigma < \sigma'$ or $\sigma = \sigma'$ and $\chi < \chi'$. For any simplex $\tau : \Delta^j \longrightarrow \Delta^n$, we let $r_k(\tau)$ be the pullback

$$\begin{array}{ccc} \Delta^{r_k(\tau)_0} & \xrightarrow{r_k(\tau)} & \Delta^{n-1} \\ \downarrow & & \downarrow d_k \\ \Delta^j & \xrightarrow{\tau} & \Delta^n \end{array}$$

We will let ι denote the map under consideration. We first prove (1). Given $\sigma \in I$ and $\chi \in J$, let $X_{\sigma,\chi}$ be the sub-marked simplicial set of $K \star_S ({}_\natural\Delta^n \times_S \mathcal{O}(S)^\natural)$ on $K \star_S ({}_\natural\Lambda^n_0 \times_S \mathcal{O}(S)^\natural)$ and simplices $(\sigma', \tau') : \Delta^i \star \Delta^j \longrightarrow K \star_S (\Delta^n \times_S \mathcal{O}(S))$ not in $K \star_S (\Lambda^n_0 \times_S \mathcal{O}(S))$ with $(\sigma', r_0(e_0 \circ \tau')) \leq (\sigma, \chi)$. If $(\sigma, \chi) < (\sigma', \chi')$, then we have an obvious inclusion $X_{\sigma,\chi} \hookrightarrow X_{\sigma',\chi'}$, and we let
$$X_{<(\sigma,\chi)} = ({}_\natural\Lambda^n_0 \times_S \mathcal{O}(S)^\natural) \bigcup (\cup_{(\sigma',\chi')<(\sigma,\chi)} X_{\sigma',\chi'}).$$

Since $K \star_S ({}_\natural\Delta^n \times_S \mathcal{O}(S)^\natural) = \operatorname{colim}_{(\sigma,\chi)\in I\times J} X_{\sigma,\chi}$, in order to show that ι is left marked anodyne it suffices to show that $X_{<(\sigma,\chi)} \hookrightarrow X_{\sigma,\chi}$ is left marked anodyne for all $(\sigma, \chi) \in I \times J$. We will say that a simplex of $X_{\sigma,\chi}$ is *new* if it does not belong to $X_{<(\sigma,\chi)}$.

Let $\sigma : \Delta^i \longrightarrow K$ be an element of I and $\chi : \Delta^j \twoheadrightarrow \Delta^{n-1}$ an element of J. Let $\lambda = (\sigma, \tau) : \Delta^i \star \Delta^j \longrightarrow K \star_S (\Delta^n \times_S \mathcal{O}(S))$ be any nondegenerate new simplex of $X_{\sigma,\chi}$, so $r_0(e_0 \circ \tau) = \chi$. Let $\bar{\chi} : \Delta^{j+1} \twoheadrightarrow \Delta^n$ be the unique epimorphism with $r_0(\bar{\chi}) = \chi$ and let $e : \Delta^1 \longrightarrow \Delta^n \times_S \mathcal{O}(S)$ be a cartesian edge over $\{0, 1\}$ with $e(1) = \tau(0)$. The inclusion $(\Delta^1)^\sharp \coprod_{\Delta^0} \Delta^j \hookrightarrow {}_\natural\Delta^{j+1}$ is right marked anodyne, so we have a lift $\bar{\tau}$ in the following diagram

$$\begin{array}{ccc} \Delta^1 \coprod_{\Delta^0} \Delta^j & \xrightarrow{e \cup \tau} & \Delta^n \times_S \mathcal{O}(S) \\ \downarrow & \overset{\bar{\tau}}{\nearrow} & \downarrow \\ \Delta^{j+1} & \xrightarrow{\bar{\chi}} & \Delta^n. \end{array}$$

By Lemma 4.10,
$$\Delta^i \star \Delta^j \coprod_{\Delta^j} {}_\natural\Delta^{j+1} \hookrightarrow \Delta^i \star {}_\natural\Delta^{j+1}$$
is right marked anodyne. Using that $(e_1 \circ \bar{\tau})(e)$ is an equivalence, we obtain a lift

$$\begin{array}{ccc} \Delta^i \star \Delta^j \coprod_{\Delta^j} {}_\natural\Delta^{j+1} & \xrightarrow{\pi\lambda \cup e_1\bar{\tau}} & S^\sim \\ \downarrow & \nearrow & \\ \Delta^i \star {}_\natural\Delta^{j+1} & & \end{array}$$

which allows us to define $\bar{\lambda} : \Delta^i \star \Delta^{j+1} \longrightarrow K \star_S (\Delta^n \times_S \mathcal{O}(S))$ extending λ and $\bar{\tau}$. Then $\bar{\lambda}$ is a nondegenerate new simplex of $X_{\sigma,\chi}$ and every face of $\bar{\lambda}$ except for $\lambda = d_{i+1}(\bar{\lambda})$ lies in $X_{<(\sigma,\chi)}$. We may thus form the pushout

$$\begin{array}{ccc} \coprod_\lambda (\Lambda^{i+j+2}_{i+1}, \{i+1, i+2\}) & \longrightarrow & X_{<(\sigma,\chi)} \\ \downarrow & & \downarrow \\ \coprod_\lambda (\Delta^{i+j+2}, \{i+1, i+2\}) & \longrightarrow & X_{<(\sigma,\chi),1} \end{array}$$

which factors the inclusion $X_{<(\sigma,\chi)} \hookrightarrow X_{(\sigma,\chi)}$ as the composition of a left marked anodyne map and an inclusion (there is one further complication involving markings: in the special case $n = 1$, $\sigma = \emptyset$,

$j=1$, we may have that $\lambda=\tau$ is a marked edge, i.e. an equivalence over 1. Then the edges of $\bar{\tau}$ are all marked, so we should form the pushout via maps $(\Lambda^2_0)^\sharp \hookrightarrow (\Delta^2)^\sharp$, which are left marked anodyne by [10, Corollary 3.1.1.7]).

Now for the inductive step suppose that we have defined a sequence of left marked anodyne maps

$$X_{<(\sigma,\chi)} \hookrightarrow \dots \hookrightarrow X_{<(\sigma,\chi),m} \subset X_{(\sigma,\chi)}$$

such that for all $0<l\leq m$ all new nondegenerate simplices in $X_{(\sigma,\chi)}$ of dimension $i+l+j$ lie in $X_{<(\sigma,\chi),l}$ and admit an extension to a $i+l+j+1$-simplex with the edge $\{i+l,i+l+1\}$ marked in $X_{<(\sigma,\chi),l}$, and no new nondegenerate simplices of dimension $>i+l+j+1$ lie in $X_{<(\sigma,\chi),l}$. Let $\lambda=(\sigma,\tau)$ be any new nondegenerate $i+m+j+1$-simplex not in $X_{<(\sigma,\chi),m}$. For $0\leq l<m$ let $\lambda_l=(\sigma,\tau_l)$ be a nondegenerate $i+m+j+1$-simplex in $X_{<(\sigma,\chi),m}$ with $d_{i+m}(\lambda_l)=d_{i+l+1}(\lambda)$ and edge $\{i+m,i+m+1\}$ marked. τ and $\tau_0,...,\tau_{m-1}$ together define a map

$$\tau' : \Lambda^{m+1}_{m+1} \star \Delta^{j-1} \longrightarrow \Delta^n \times_S \mathcal{O}(S)$$

where the domain of τ is the subset $\{0,...,m-1,m+1,...,m+j+1\}$ and the domain of τ_l is the subset $\{0,...,\widehat{l},...,m+j+1\}$. Observe that the map $\Lambda^{m+1\natural}_{m+1} \star \Delta^{j-1} \hookrightarrow \Delta^{m+1\natural} \star \Delta^{j-1}$ is right marked anodyne, since it factors as

$$\Lambda^{m+1\natural}_{m+1} \star \Delta^{j-1} \hookrightarrow \Delta^{m+1\natural} \coprod_{\Lambda^{m+1\natural}_{m+1}} \Lambda^{m+1\natural}_{m+1} \star \Delta^{j-1} \hookrightarrow \Delta^{m+1\natural} \star \Delta^{j-1}$$

where the first map is obtained as the pushout of the right marked anodyne map $\Lambda^{m+1\natural}_{m+1} \hookrightarrow \Delta^{m+1\natural}$ along the inclusion $\Lambda^{m+1\natural}_{m+1} \hookrightarrow \Lambda^{m+1\natural}_{m+1} \star \Delta^{j-1}$ and the second map is obtained by marking a common edge of an inner anodyne map. Let $\bar{\chi}:\Delta^{m+j+1} \twoheadrightarrow \Delta^n$ be the unique epimorphism with $r_0(\bar{\chi})=\chi$. Then we have a lift $\bar{\tau}$ in the following commutative diagram

$$\begin{array}{ccc} \Lambda^{m+1}_{m+1} \star \Delta^{j-1} & \xrightarrow{\tau'} & \Delta^n \times_S \mathcal{O}(S) \\ \downarrow & \overset{\bar{\tau}}{\nearrow} & \downarrow \\ \Delta^{m+1} \star \Delta^{j-1} & \xrightarrow{\bar{\chi}} & \Delta^n. \end{array}$$

By Lemma 4.10, the map

$$\Delta^i \star \Lambda^{m+1\natural}_{m+1} \star \Delta^{j-1} \coprod_{\Lambda^{m+1\natural}_{m+1} \star \Delta^{j-1}} \Delta^{m+1\natural} \star \Delta^{j-1} \hookrightarrow \Delta^i \star \Delta^{m+1\natural} \star \Delta^{j-1}$$

is right marked anodyne. Since $(e_1 \circ \bar{\tau})(\{m,m+1\})$ is an equivalence, we may extend $(\cup_l \pi\lambda_l) \cup \pi\lambda \cup e_1\bar{\tau}$ to a map $\Delta^{i+m+j+2} \longrightarrow S$, which defines a nondegenerate $(i+m+j+2)$-simplex $\bar{\lambda}$ with λ as its $(i+m+1)$th face and which extends $\bar{\tau}$. By construction every other face of $\bar{\lambda}$ lies in $X_{<(\sigma,\chi),m}$. Thus we may form the pushout

$$\begin{array}{ccc} \coprod_\lambda (\Lambda^{i+m+j+2}_{i+m+1}, \{i+m+1,i+m+2\}) & \longrightarrow & X_{<(\sigma,\chi),m} \\ \downarrow & & \downarrow \\ \coprod_\lambda (\Delta^{i+m+j+2}, \{i+m+1,i+m+2\}) & \longrightarrow & X_{<(\sigma,\chi),m+1} \end{array}$$

and complete the inductive step (again, there is one further complication involving markings: in the special case $i=-1$, $n=1$, $j=0$, $m=1$, we may have that λ is marked. Then every edge of $\bar{\lambda}$ is marked since $(\Lambda^2_2)^\sharp \hookrightarrow (\Delta^2)^\sharp$ is right marked anodyne, and we form the pushout along maps $(\Lambda^2_1)^\sharp \hookrightarrow (\Delta^2)^\sharp$). Passing to the colimit, we deduce that $X_{<(\sigma,\chi)} \hookrightarrow X_{\sigma,\chi}$ is marked left anodyne, which completes the proof.

For (1'), simply observe that if $i>-1$ we are attaching along inner horns.

We now modify the above proof to prove (2). Let $X_{\sigma,\chi}$ be the sub-simplicial set of $K \star_S (\Delta^n \times_S C)$ on $K \star_S (\Lambda^n_k \times_S C)$ and simplices $(\sigma',\tau') : \Delta^i \star \Delta^j \longrightarrow K \star_S (\Delta^n \times_S C)$ not in $K \star_S (\Lambda^n_k \times_S C)$ with $(\sigma', r_k(e_0 \circ \tau')) \leq (\sigma,\chi)$. Let $X_{<(\sigma,\chi)} = (K \star (\Lambda^n_k \times_S C)) \bigcup (\cup_{(\sigma',\chi')<(\sigma,\chi)} X_{\sigma',\chi'})$. We will show that $X_{<(\sigma,\chi)} \hookrightarrow X_{\sigma,\chi}$ is inner anodyne for all $(\sigma,\chi) \in I \times J$.

Let $\sigma : \Delta^i \longrightarrow K$ be an element of I, $\chi : \Delta^j \twoheadrightarrow \Delta^{n-1}$ an element of J, and let k' be the first vertex of χ with $\chi(k') = k$. Let $\lambda = (\sigma, \tau) : \Delta^i \star \Delta^j \longrightarrow K \star_S (\Delta^n \times_S C)$ be any nondegenerate new simplex of $X_{\sigma,\chi}$, so $r_k(e_0 \circ \tau) = \chi$. Let $\bar{\chi} : \Delta^{j+1} \twoheadrightarrow \Delta^n$ be the unique epimorphism with $r_k(\bar{\chi}) = \chi$. Combining [10, Lemma 2.1.2.3] and Lemma 4.10, we see that the inclusion

$$d_{k'} : \Delta^j = \Delta^{k'-1} \star \Delta^{j-k'} \hookrightarrow \Delta^{k'-1} \star_{\natural} \Delta^{j-k'+1}$$

is right marked anodyne, so we have a lift $\bar{\tau}$ in the following diagram

$$\begin{array}{ccc} \Delta^j & \xrightarrow{\tau} & \Delta^n \times_S C \\ \downarrow & \overset{\bar{\tau}}{\nearrow} & \downarrow \\ \Delta^{j+1} & \xrightarrow{\bar{\chi}} & \Delta^n \end{array}$$

where $\bar{\tau}(\{k', k'+1\})$ is a cartesian edge. By Lemma 4.9, $\Delta^i \star \Delta^j \coprod_{\Delta^j} \Delta^{j+1} \hookrightarrow \Delta^i \star \Delta^{j+1}$ is inner anodyne. We thus obtain an extension

$$\begin{array}{ccc} \Delta^i \star \Delta^j \coprod_{\Delta^j} \Delta^{j+1} & \xrightarrow{\pi\lambda \cup e_1 \bar{\tau}} & S \\ \downarrow & \nearrow & \\ \Delta^i \star \Delta^{j+1} & & \end{array}$$

which allows us to define $\bar{\lambda} : \Delta^i \star \Delta^{j+1} \longrightarrow K \star_S (\Delta^n \times_S C)$ extending λ and $\bar{\tau}$. Then $\bar{\lambda}$ is nondegenerate and every face of $\bar{\lambda}$ except for $\lambda = d_{i+k'+1}(\bar{\lambda})$ lies in $X_{<(\sigma,\chi)}$. We may thus form the pushout

$$\begin{array}{ccc} \coprod_\lambda \Lambda^{i+j+2}_{i+k'+1} & \longrightarrow & X_{<(\sigma,\chi)} \\ \downarrow & & \downarrow \\ \coprod_\lambda \Delta^{i+j+2} & \longrightarrow & X_{<(\sigma,\chi),1} \end{array}$$

which factors the inclusion $X_{<(\sigma,\chi)} \hookrightarrow X_{(\sigma,\chi)}$ as the composition of an inner anodyne map and an inclusion.

Now for the inductive step suppose that we have defined a sequence of inner anodyne maps

$$X_{<(\sigma,\chi)} \hookrightarrow ... \hookrightarrow X_{<(\sigma,\chi),m} \subset X_{(\sigma,\chi)}$$

such that for all $0 < l \leq m$ all new nondegenerate simplices in $X_{(\sigma,\chi)}$ of dimension $i + l + j$ lie in $X_{<(\sigma,\chi),l}$ and admit an extension to a $i+l+j+1$-simplex such that the edge $\{i+k'+l, i+k'+l+1\}$ is sent to a cartesian edge of $\Delta^n \times_S C$, and no new nondegenerate simplices of dimension $> i+l+j+1$ lie in $X_{<(\sigma,\chi),l}$. Let $\lambda = (\sigma, \tau)$ be any new nondegenerate $i+m+j+1$-simplex not in $X_{<(\sigma,\chi),m}$. For $0 \leq l < m$ let $\lambda_l = (\sigma, \tau_l)$ be a nondegenerate $i+m+j+1$-simplex in $X_{<(\sigma,\chi),m}$ with $d_{i+m+k'}(\lambda_l) = d_{i+l+k'+1}(\lambda)$. τ and $\tau_0, ..., \tau_{m-1}$ together define a map

$$\tau' : \Delta^{k'-1} \star \Lambda^{m+1}_{m+1} \star \Delta^{j-k'-1} \longrightarrow \Delta^n \times_S C$$

where the domain of τ is the subset $\{0, ..., k'+m-1, k'+m+1, ..., m+j+1\}$ and the domain of τ_l is the subset $\{0, ..., \widehat{k'+l}, ..., m+j+1\}$. The map

$$\Delta^{k'-1} \star \Lambda^{m+1\natural}_{m+1} \star \Delta^{j-k'-1} \hookrightarrow \Delta^{k'-1} \star \Delta^{m+1\natural} \star \Delta^{j-k'-1}$$

is $\Delta^{k'-1}$ joined with a right marked anodyne map, so is right marked anodyne by Lemma 4.10. Let $\bar{\chi} : \Delta^{m+j+1} \twoheadrightarrow \Delta^n$ be the unique epimorphism with $r_k(\bar{\chi}) = \chi$. Then we have a lift $\bar{\tau}$ in the following commutative diagram

$$\begin{array}{ccc} \Delta^{k'-1} \star \Lambda^{m+1}_{m+1} \star \Delta^{j-k'-1} & \xrightarrow{\tau'} & \Delta^n \times_S C \\ \downarrow & \overset{\bar{\tau}}{\nearrow} & \downarrow \\ \Delta^{m+j+1} & \xrightarrow{\bar{\chi}} & \Delta^n \end{array}$$

such that $\bar{\tau}(\{k'+m, k'+m+1\})$ is a cartesian edge. By Lemma 4.9, the map

$$\Delta^i \star \Delta^{k'-1} \star \partial\Delta^m \star \Delta^{j-k'} \coprod_{\Delta^{k'-1} \star \partial\Delta^m \star \Delta^{j-k'}} \Delta^{m+j+1} \hookrightarrow \Delta^{i+m+j+2}$$

is inner anodyne. Therefore, we may extend $(\cup_l \pi\lambda_l) \cup \pi\lambda \cup e_1\bar{\tau}$ to a map $\Delta^{i+m+j+2} \longrightarrow S$, which defines a nondegenerate $(i+m+j+2)$-simplex $\bar{\lambda}$ with λ as its $(i+k'+m+1)$th face and which extends $\bar{\tau}$. By construction every other face of $\bar{\lambda}$ lies in $X_{<(\sigma,\chi),m}$. Thus we may form the pushout

$$\begin{array}{ccc} \coprod_\lambda \Lambda^{i+m+j+2}_{i+k'+m+1} & \longrightarrow & X_{<(\sigma,\chi),m} \\ \downarrow & & \downarrow \\ \coprod_\lambda \Delta^{i+m+j+2} & \longrightarrow & X_{<(\sigma,\chi),m+1} \end{array}$$

and complete the inductive step. Passing to the colimit, we deduce that $X_{<(\sigma,\chi)} \hookrightarrow X_{\sigma,\chi}$ is inner anodyne, which completes the proof.

We finally modify the above proof to prove (3). Given $\sigma \in I$ and $\chi \in J$, let $X_{\sigma,\chi}$ be the sub-marked simplicial set of $K \star_S \Delta^{n\natural}$ on $K \star_S \Lambda^{n\natural}_n$ and simplices $(\sigma', \tau') : \Delta^i \star \Delta^j \longrightarrow K \star_S \Delta^{n\natural}$ not in $K \star_S \Lambda^{n\natural}_n$ with $(\sigma', r_n(\tau')) \leq (\sigma, \chi)$. Let $X_{<(\sigma,\chi)} = (K \star_S \Lambda^{n\natural}_n) \bigcup (\cup_{(\sigma',\chi')<(\sigma,\chi)} X_{\sigma',\chi'})$. We will show that $X_{<(\sigma,\chi)} \hookrightarrow X_{\sigma,\chi}$ is right marked anodyne for all $(\sigma,\chi) \in I \times J$.

Let $\sigma : \Delta^i \longrightarrow K$ be an element of I and $\chi : \Delta^j \twoheadrightarrow \Delta^{n-1}$ an element of J. Let $\lambda = (\sigma, \tau) : \Delta^i \star \Delta^j \longrightarrow K \star_S \Delta^{n\natural}$ be any nondegenerate new simplex of $X_{\sigma,\chi}$, so $r_n(\tau) = \chi$. Let $\bar{\chi} : \Delta^{j+1} \twoheadrightarrow \Delta^n$ be the unique epimorphism with $r_n(\bar{\chi}) = \chi$. By Lemma 4.9, the inclusion

$$\Delta^i \star \Delta^j \coprod_{\Delta^j} \Delta^{j+1} \hookrightarrow \Delta^i \star \Delta^{j+1}$$

is inner anodyne, so we have an extension in the following diagram

$$\begin{array}{ccc} \Delta^i \star \Delta^j \coprod_{\Delta^j} \Delta^{j+1} & \xrightarrow{\pi\lambda \cup \pi_2\bar{\chi}} & S \\ \downarrow & \nearrow & \\ \Delta^i \star \Delta^{j+1} & & \end{array}$$

which allows us to define $\bar{\lambda} : \Delta^i \star \Delta^{j+1} \longrightarrow K \star_S \Delta^{n\natural}$ extending λ and $\bar{\chi}$. Then $\bar{\lambda}$ is nondegenerate and every face of $\bar{\lambda}$ except for $\lambda = d_{i+j+2}(\bar{\lambda})$ lies in $X_{<(\sigma,\chi)}$. We may thus form the pushout

$$\begin{array}{ccc} \coprod_\lambda \Lambda^{i+j+2\natural}_{i+j+2} & \longrightarrow & X_{<(\sigma,\chi)} \\ \downarrow & & \downarrow \\ \coprod_\lambda \Delta^{i+j+2\natural} & \longrightarrow & X_{<(\sigma,\chi),1} \end{array}$$

which factors the inclusion $X_{<(\sigma,\chi)} \longrightarrow X_{(\sigma,\chi)}$ as the composition of a right marked anodyne map and an inclusion.

Now for the inductive step suppose that we have defined a sequence of right marked anodyne maps

$$X_{<(\sigma,\chi)} \hookrightarrow \ldots \hookrightarrow X_{<(\sigma,\chi),m} \subset X_{(\sigma,\chi)}$$

such that for all $0 < l \leq m$ all new nondegenerate simplices in $X_{(\sigma,\chi)}$ of dimension $i+l+j$ lie in $X_{<(\sigma,\chi),l}$ and admit an extension to a $i+l+j+1$-simplex, and no new nondegenerate simplices of dimension $> i+l+j+1$ lie in $X_{<(\sigma,\chi),l}$. Let $\lambda = (\sigma,\tau)$ be any new nondegenerate $i+m+j+1$-simplex not in $X_{<(\sigma,\chi),m}$. For $0 < l \leq m$ let $\lambda_l = (\sigma, \tau_l)$ be a nondegenerate $i+m+j+1$-simplex in $X_{<(\sigma,\chi),m}$ with $d_{i+m+j+1}(\lambda_l) = d_{i+j+l+1}(\lambda)$ (note that $\tau_l = \tau$). By Lemma 4.9, the map

$$\Delta^i \star \Delta^j \star \partial\Delta^m \coprod_{\Delta^j \star \partial\Delta^m} \Delta^j \star \Delta^m \hookrightarrow \Delta^i \star \Delta^j \star \Delta^m$$

is inner anodyne. Therefore, we may extend $\pi\lambda \cup (\cup_l \pi\lambda_l)$ to a map $\Delta^{i+j+m+2} \longrightarrow S$ and define a $(i+j+m+2)$-simplex $\bar{\lambda}$ of $K \star \Delta^{n\natural}$ with $d_{i+j+m+2}\bar{\lambda} = \lambda$ and $d_{i+j+l+1}\bar{\lambda} = \lambda + l$. By construction every face of $\bar{\lambda}$ except for λ lies in $X_{<(\sigma,\chi),m}$. Thus we may form the pushout

$$\begin{array}{ccc} \coprod_\lambda \Lambda^{i+j+m+2\natural}_{i+j+m+2} & \longrightarrow & X_{<(\sigma,\chi),m} \\ \downarrow & & \downarrow \\ \coprod_\lambda \Delta^{i+j+m+2\natural} & \longrightarrow & X_{<(\sigma,\chi),m+1} \end{array}$$

and complete the inductive step. Passing to the colimit, we deduce that $X_{<(\sigma,\chi)} \hookrightarrow X_{\sigma,\chi}$ is right marked anodyne, which completes the proof. $\square$

4.12. **Remark.** The proof of Proposition 4.11 can be adapted to show that for any cartesian fibration $C \longrightarrow S$, ${}_\natural\Lambda^n_0 \times_S C^\natural \hookrightarrow {}_\natural\Delta^n \times_S C^\natural$ is marked left anodyne (in the $\sigma = \emptyset$ case, we only use that $e_0 : \mathcal{O}(S) \longrightarrow S$ is a cartesian fibration). As well, letting $K = \emptyset$, part (2) of Proposition 4.11 shows that $\Lambda^n_k \times_S C \hookrightarrow \Delta^n \times_S C$ is inner anodyne. This refines the theorem that marked left anodyne maps resp. inner anodyne maps pullback to cocartesian equivalences resp. categorical equivalences along cartesian fibrations.

For later use, we state a criterion for showing that a functor is left Quillen.

4.13. **Lemma.** *Let $\mathcal{M}$ and $\mathcal{N}$ be model categories and let $F : \mathcal{M} \longrightarrow \mathcal{N}$ be a functor which preserves cofibrations. Let I be a weakly saturated* [10, Definition A.1.2.2] *subset of the trivial cofibrations in $\mathcal{M}$ such that for every object $A \in \mathcal{M}$, we have a map $f : A \longrightarrow A'$ where $f \in I$ and A' is fibrant. Then F preserves trivial cofibrations if and only if*

(1) For every $f \in I$, $F(f)$ is a trivial cofibration.
(2) F preserves trivial cofibrations between fibrant objects.

Proof. The 'only if' direction is obvious. For the other direction, let $A \longrightarrow B$ be a trivial cofibration in $\mathcal{M}$. We may form the diagram

$$\begin{array}{ccccc} A & \longrightarrow & B & & \\ \downarrow & & \downarrow & \searrow & \\ A' & \longrightarrow & A' \coprod_A B & \longrightarrow & (A' \coprod_A B)' \end{array}$$

where the vertical and lower right horizontal arrows are in I. Then our two assumptions along with the two-out-of-three property of the weak equivalences shows that $F(A) \longrightarrow F(B)$ is a trivial cofibration. $\square$

4.14. **Lemma.** *Let K be a simplicial set over S. Then*

$$K \star_S -, - \star_S K : s\mathbf{Set}_{/S} \longrightarrow s\mathbf{Set}_{K//S}$$

are left adjoints. Similarly, for K a marked simplicial set over S,

$$K \star_S -, - \star_S K : s\mathbf{Set}^+_{/S} \longrightarrow s\mathbf{Set}^+_{K//S}$$

are left adjoints.

Proof. We will prove that $K \star_S -$ is a left adjoint in the unmarked case and leave the other cases to the reader. Let F denote $K \star_S -$ and define a functor $G : s\mathbf{Set}_{K//S} \longrightarrow s\mathbf{Set}_{/S}$ by letting $G(K \longrightarrow C)$ be the simplicial set over S which satisfies

$$\mathrm{Hom}_{/S}(\Delta^n, G(K \longrightarrow C)) = \mathrm{Hom}_{K//S}(K \star_S \Delta^n, C);$$

this is evidently natural in $K \longrightarrow C$. Define a unit map $\eta : \mathrm{id} \longrightarrow GF$ on objects X by sending $\sigma : \Delta^n \longrightarrow X$ to $K \star_S \sigma : K \star_S \Delta^n \longrightarrow K \star_S X$, which corresponds to $\Delta^n \longrightarrow G(K \star_S X)$. Define a counit map $\eta : FG \longrightarrow \mathrm{id}$ on objects $K \longrightarrow C$ by sending $\lambda = (\sigma, \tau) : \Delta^i \star \Delta^j \longrightarrow K \star_S G(K \longrightarrow C)$ to $\Delta^i \star \Delta^j \xrightarrow{(\sigma,\mathrm{id})} K \star_S \Delta^j \xrightarrow{\tau'} C$, where τ' corresponds to $\tau : \Delta^j \longrightarrow G(K \longrightarrow C)$. Then it is straightforward to verify the triangle identities, so F is adjoint to G. $\square$

For the following pair of results, endow $s\mathbf{Set}^+_{/S}$ with the cocartesian model structure and $s\mathbf{Set}^+_{K//S} = (s\mathbf{Set}^+_{/S})_{K/}$ with the model structure created by the forgetful functor to $s\mathbf{Set}^+_{/S}$.

4.15. **Theorem.** *Let K be a marked simplicial set over S. The functor*

$$K \star_S (- \times_S \mathcal{O}(S)^\sharp) : s\mathbf{Set}^+_{/S} \longrightarrow s\mathbf{Set}^+_{K//S}$$

is left Quillen.

Proof. We will denote the functor in question by F. First observe that F is the composite of the three left adjoints e_0^*, $e_{1!}$, and $K \star_S -$, so F is a left adjoint. F evidently preserve cofibrations, so it only remains to check that F preserves the trivial cofibrations. We first verify that F preserves the left marked anodyne maps. Since F preserves colimits it suffices to check that F preserves a collection of morphisms which generate the left marked anodyne maps as a weakly saturated class. We verify that F preserves the four classes of maps enumerated in [10, Definition 3.1.1.1].

(1): For $\iota : (\Lambda^n_k)^\flat \longrightarrow (\Delta^n)^\flat$, $0 < k < n$, the underlying map of simplicial sets of $F(\iota)$ is inner anodyne by Proposition 4.11. $F(\iota)$ is obtained by marking common edges of an inner anodyne map, so is left marked anodyne.

(2): For $\iota : {}_\natural\Lambda^n_0 \longrightarrow {}_\natural\Delta^n$, we observe that the map

$$K \star_S ({}_\natural\Lambda^n_0 \times_S \mathcal{O}(S)^\sharp) \coprod_{K\star_S({}_\natural\Lambda^n_0 \times_S \mathcal{O}(S)^\natural)} K \star_S ({}_\natural\Delta^n \times_S \mathcal{O}(S)^\natural) \longrightarrow K \star_S ({}_\natural\Delta^n \times_S \mathcal{O}(S)^\sharp)$$

in the case $n = 1$ is marked left anodyne, since every marked edge in the codomain factors as a composite of two marked edges in the domain, and is the identity if $n > 1$. It thus suffices to show that $K \star_S ({}_\natural\Lambda^n_0 \times_S \mathcal{O}(S)^\natural) \longrightarrow K \star_S ({}_\natural\Delta^n \times_S \mathcal{O}(S)^\natural)$ is left marked anodyne, which is the content of part 1 of 4.11.

(3) and (4): In both of these cases one has a map of marked simplicial sets $A \longrightarrow B$ whose underlying map is an isomorphism of simplicial sets. Then

$$\begin{array}{ccc} A & \longrightarrow & F(A) \\ \downarrow & & \downarrow \\ B & \longrightarrow & F(B) \end{array}$$

is a pushout square, so $F(A) \longrightarrow F(B)$ is left marked anodyne if $A \longrightarrow B$ is.

Next, let $f : {}_\natural C \longrightarrow {}_\natural D$ be a cocartesian equivalence between cocartesian fibrations over S. Let $g : {}_\natural D \longrightarrow {}_\natural C$ be a homotopy inverse of f, so that there exists a homotopy $h : {}_\natural C \times (\Delta^1)^\sharp \longrightarrow {}_\natural C$ over S from id_C to $g \circ f$. Define a map

$$\phi : (K \star_S ({}_\natural C \times_S \mathcal{O}(S)^\sharp)) \times (\Delta^1)^\sharp \longrightarrow K \star_S (({}_\natural C \times_S \mathcal{O}(S)^\sharp) \times (\Delta^1)^\sharp)$$

by sending a $(i + j + 1)$-simplex (λ, α) given by the data $\sigma : \Delta^i \longrightarrow K$, $\tau : \Delta^j \longrightarrow {}_\natural C \times_S \mathcal{O}(S)^\sharp$, $\pi \circ \lambda : \Delta^{i+j+1} \longrightarrow \Delta^1$, $\alpha : \Delta^{i+j+1} \longrightarrow \Delta^1$ to a $i + j + 1$-simplex λ' given by the data σ, $(\tau, \alpha \circ \iota)$, $\pi \circ \lambda$ where $\iota : \Delta^j \longrightarrow \Delta^i \star \Delta^j$ is the inclusion. It is easy to see that ϕ restricts to an isomorphism on $(K \star_S ({}_\natural C \times_S \mathcal{O}(S)^\sharp)) \times \partial\Delta^1$. We deduce that $F(h) \circ \phi$ is a homotopy from $F(g \circ f)$ to the identity. A similar argument concerning a chosen homotopy from $f \circ g$ to id_D shows that $F(f)$ is a cocartesian equivalence.

Finally, invoking Lemma 4.13 completes the proof. □

4.16. **Theorem.** *Let K be a marked simplicial set over S. The functor*

$$- \star_S K : s\mathbf{Set}^+_{/S} \longrightarrow s\mathbf{Set}^+_{K//S}$$

is left Quillen.

Proof. As with the proof of Theorem 4.15, the proof will be an application of Lemma 4.13. We first verify that $- \star_S K$ preserves the four classes of left marked anodyne maps enumerated in [10, Definition 3.1.1.1]. (1) is handled by the dual of part (2) of Proposition 4.11. (2) is handled by the dual of part (3) of Proposition 4.11. (3) and (4) are handled as in the proof of Theorem 4.15. Finally, the case of $A \longrightarrow B$ a cocartesian equivalence between fibrant objects is also handled as in the proof of Theorem 4.15. □

4.17. **Definition.** Let $K, C \longrightarrow S$ be marked simplicial sets over S and let $p : K \longrightarrow C$ be a map over S. Define the marked simplicial set $C_{(p,S)/} \longrightarrow S$ as the value of the right adjoint to $K \star_S (- \times_S \mathcal{O}(S)^\sharp)$ on $K \longrightarrow C \longrightarrow S$ in $s\mathbf{Set}^+_{K//S}$. By Theorem 4.15, if $C \longrightarrow S$ is a S-category, then $C_{(p,S)/} \longrightarrow S$ is a S-category. We will refer to $C_{(p,S)/}$ as a *S-undercategory* of C.

Dually, define the marked simplicial set $C_{/(p,S)} \longrightarrow S$ as the value of the right adjoint to $- \star_S (K \times_S \mathcal{O}(S)^\sharp)$ on $K \longrightarrow C \longrightarrow S$ in $s\mathbf{Set}^+_{K//S}$. By Theorem 4.16 applied to $K \times_S \mathcal{O}(S)^\sharp$, if $C \longrightarrow S$ is a S-category, then $C_{/(p,S)} \longrightarrow S$ is a S-category. We will refer to $C_{/(p,S)}$ as a *S-overcategory* of C.

In the sequel, we will focus our attention on the S-undercategory and leave proofs of the evident dual assertions to the reader.

Functoriality in the diagram. We now study the functoriality of the S-undercategory with respect to the diagram category. Given maps $f : K \longrightarrow L$ and $p : L \longrightarrow X$ of marked simplicial sets over S, we have an induced map $X_{(p,S)/} \longrightarrow X_{(pf,S)/}$, which in terms of the functors that $X_{(p,S)/}$ and $X_{(pf,S)/}$ represent is given by precomposing $L \star_S (A \times_S \mathcal{O}(S)^\sharp) \longrightarrow X$ by $f \star_S \mathrm{id}$.

Recall that for a category $\mathcal{M}$ admitting pushouts and a map $f : K \longrightarrow L$, we have an adjunction

$$f_! : \mathcal{M}_{K/} \rightleftarrows \mathcal{M}_{L/} : f^*$$

where $f_!(K \longrightarrow X) = X \coprod_K L$ and $f^*(L \xrightarrow{p} X) = p \circ f$. If $\mathcal{M}$ is a model category and $\mathcal{M}_{K/}$, $\mathcal{M}_{L/}$ are provided with the model structures induced from $\mathcal{M}$, then $(f_!, f^*)$ is a Quillen adjunction. Moreover, if $\mathcal{M}$ is a left proper model category and f is a weak equivalence, then $(f_!, f^*)$ is a Quillen equivalence.

4.18. **Proposition.** *Let $f : K \longrightarrow L$ be a cocartesian equivalence in $s\mathbf{Set}^+_{/S}$. Let C be a S-category and let $p : L \longrightarrow {}_\natural C$ be a map. Then ${}_\natural C_{(p,S)/} \longrightarrow {}_\natural C_{(pf,S)/}$ is a cocartesian equivalence in $s\mathbf{Set}^+_{/S}$.*

Proof. Let $F = f_! \circ (K \star_S (- \times_S \mathcal{O}(S)^\sharp))$ and let $F' = L \star_S (- \times_S \mathcal{O}(S)^\sharp)$. Let G and G' be the right adjoints to F and F', respectively. Let $\alpha : F \longrightarrow F'$ be the evident natural transformation and let $\beta : G' \longrightarrow G$ be the dual natural transformation, defined by $G' \xrightarrow{\eta_{G'}} GFG' \xrightarrow{G\alpha G'} GF'G' \xrightarrow{G\epsilon'} G$. Then $\beta_C : {}_\natural C_{(p,S)/} \longrightarrow {}_\natural C_{(pf,S)/}$ is the map under consideration. By Theorem 4.16, α_X is a cocartesian equivalence for all $X \in s\mathbf{Set}^+_{/S}$. Therefore, by [8, Corollary 1.4.4(b)], β_C is a cocartesian equivalence. □

4.19. **Proposition.** *Consider a commutative diagram of marked simplicial sets*

$$\begin{array}{ccc} K & \longrightarrow & C \\ {\scriptstyle i}\downarrow & \overset{p}{\nearrow} & \downarrow{\scriptstyle q} \\ L & \longrightarrow & D \end{array}$$

where i is a cofibration and q is a fibration.

1. *The map*
$$C_{(p,S)/} \longrightarrow C_{(pi,S)/} \times_{D_{(qpi,S)/}} D_{(qp,S)/}$$
is a fibration.
2. *Let $K = \emptyset$ and $D = S^\sharp$. Then the map*
$$C_{(p,S)/} \longrightarrow C_{(pi,S)/} \cong \underline{\mathrm{Fun}}_S(S^\sharp, C)$$
is a left fibration (of the underlying simplicial sets).

Proof. (1) Given a trivial cofibration $A \longrightarrow B$, we need to solve lifting problems of the form

$$\begin{array}{ccc} L \star_S (A \times_S \mathcal{O}(S)^\sharp) \coprod_{K \star_S (A \times_S \mathcal{O}(S)^\sharp)} K \star_S (B \times_S \mathcal{O}(S)^\sharp) & \longrightarrow & C \\ \downarrow & & \downarrow \\ L \star_S (B \times_S \mathcal{O}(S)^\sharp) & \longrightarrow & D. \end{array}$$

But the lefthand map is a trivial cofibration by Theorem 4.15.

(2) We need to solve lifting problems of the form

$$\begin{array}{ccc} (\Delta^n)^\flat \times_S \mathcal{O}(S)^\sharp \coprod_{(\Lambda^n_i)^\flat} K \star_S ((\Lambda^n_i)^\flat \times_S \mathcal{O}(S)^\sharp) & \longrightarrow & C \\ \downarrow & & \downarrow \\ K \star_S ((\Delta^n)^\flat \times_S \mathcal{O}(S)^\sharp) & \longrightarrow & S \end{array}$$

where $0 \leq i < n$. But the lefthand map is a trivial cofibration by Proposition 4.11 (1') and (2). □

Combining (2) of the above proposition with Lemma 3.6 (2) (which supplies a trivial marked fibration $\underline{\mathrm{Fun}}_S(S^\sharp, C) \longrightarrow C$), we obtain a map $C_{(p,S)/} \longrightarrow C$ which is a marked fibration and a left fibration, and such that for any $f : K \longrightarrow L$, the triangle

$$\begin{array}{ccc} C_{(p,S)/} & \longrightarrow & C_{(pf,S)/} \\ & \searrow \quad \swarrow & \\ & C & \end{array}$$

commutes.

The universal mapping property of the S-slice. Because the S-join and slice Quillen adjunction is not simplicial, we do not immediately obtain a universal mapping property characterizing the S-slice. Our goal in this subsection is to supply such a universal mapping property (Proposition 4.25). We first recall how to slice Quillen bifunctors. Suppose $\mathcal{V}$ is a closed symmetric monoidal category and $\mathcal{M}$ is enriched, tensored, and cotensored over $\mathcal{V}$. Denote the internal hom by

$$\underline{\mathrm{Hom}}(-,-) : \mathcal{M}^{op} \times \mathcal{M} \longrightarrow \mathcal{V}.$$

Define bifunctors

$$\underline{\mathrm{Hom}}_{x/}(-,-) : \mathcal{M}^{op}_{x/} \times \mathcal{M}_{x/} \longrightarrow \mathcal{V}$$
$$\underline{\mathrm{Hom}}_{/x}(-,-) : \mathcal{M}^{op}_{/x} \times \mathcal{M}_{/x} \longrightarrow \mathcal{V}$$

on objects $f : x \longrightarrow a, g : x \longrightarrow b$ and $f' : a \longrightarrow x, g' : b \longrightarrow x$ to be pullbacks

$$\begin{array}{ccc} \underline{\mathrm{Hom}}_{x/}(f,g) & \longrightarrow & \underline{\mathrm{Hom}}(a,b) \\ \downarrow & & \downarrow f^* \\ 1 & \xrightarrow{g} & \underline{\mathrm{Hom}}(x,b) \end{array} \qquad \begin{array}{ccc} \underline{\mathrm{Hom}}_{/x}(f',g') & \longrightarrow & \underline{\mathrm{Hom}}(a,b) \\ \downarrow & & \downarrow g'_* \\ 1 & \xrightarrow{f'} & \underline{\mathrm{Hom}}(a,x) \end{array}$$

and on morphisms in the obvious way (we abusively denote by $g : 1 \longrightarrow \underline{\mathrm{Hom}}(x,b)$ the map corresponding to g under the natural isomorphisms $\underline{\mathrm{Hom}}(1, \underline{\mathrm{Hom}}(x,b)) \cong \underline{\mathrm{Hom}}(1 \otimes x, b) \cong \underline{\mathrm{Hom}}(x,b)$, and likewise for f'). It is easy to see that $\underline{\mathrm{Hom}}_{x/}$ and $\underline{\mathrm{Hom}}_{/x}$ preserve limits separately in each variable.

4.20. **Lemma.** *In the above situation let $\mathcal{M}$ be a model category and $\mathcal{P}$ be a monoidal model category. If $\underline{\mathrm{Hom}}(-,-)$ is a right Quillen bifunctor, then $\underline{\mathrm{Hom}}_{x/}(-,-)$ and $\underline{\mathrm{Hom}}_{/x}(-,-)$ are right Quillen bifunctors, where we endow $\mathcal{M}_{x/}$ and $\mathcal{M}_{/x}$ with the model structures created by the forgetful functor to $\mathcal{M}$.*

Proof. We prove the assertion for $\underline{\mathrm{Hom}}_{x/}(-,-)$, the proof for $\underline{\mathrm{Hom}}_{/x}(-,-)$ being identical. Let $i : a \longrightarrow b$ and $f : c \longrightarrow d$ be morphisms in $\mathcal{M}_{x/}$ (so they are compatible with the structure maps $\pi_a, ..., \pi_d$). In the commutative diagram

$$\begin{array}{ccc} \underline{\mathrm{Hom}}_{x/}(\pi_b, \pi_c) & \longrightarrow & \underline{\mathrm{Hom}}(b,c) \\ \downarrow & & \downarrow \\ \underline{\mathrm{Hom}}_{x/}(\pi_a, \pi_c) \times_{\underline{\mathrm{Hom}}_{x/}(\pi_a,\pi_d)} \underline{\mathrm{Hom}}_{x/}(\pi_b, \pi_d) & \longrightarrow & \underline{\mathrm{Hom}}(a,c) \times_{\underline{\mathrm{Hom}}(a,d)} \underline{\mathrm{Hom}}(b,d) \\ \downarrow & & \downarrow \\ 1 & \longrightarrow & \underline{\mathrm{Hom}}(x,c) \end{array}$$

it is easy to see that the lower square and the rectangle are pullback squares, so the upper square is a pullback square. It is now clear that if $\underline{\mathrm{Hom}}(-,-)$ is a right Quillen bifunctor, then $\underline{\mathrm{Hom}}_{x/}(-,-)$ is as well. □

We apply Lemma 4.20 to the bifunctors

$$\begin{aligned}\mathrm{Map}_{K//S}(-,-) :& s\mathbf{Set}^{+\,op}_{K//S} \times s\mathbf{Set}^{+}_{K//S} \longrightarrow s\mathbf{Set}_{\mathrm{Quillen}}\\ \mathrm{Fun}_{K//S}(-,-) :& s\mathbf{Set}^{+\,op}_{K//S} \times s\mathbf{Set}^{+}_{K//S} \longrightarrow s\mathbf{Set}_{\mathrm{Joyal}}\end{aligned}$$

induced by $\mathrm{Map}_S(-,-)$ and $\mathrm{Fun}_S(-,-)$.

4.21. **Lemma.** *Let K, A, and B be simplicial sets and define a map*

$$A \times (K \star B) \longrightarrow K \star (A \times B)$$

by sending the data $(\Delta^n \longrightarrow A, \Delta^k \longrightarrow K, \Delta^{n-k-1} \longrightarrow B)$ of a n-simplex of $A \times (K \star B)$ to the data $(\Delta^k \longrightarrow K, \Delta^{n-k-1} \longrightarrow A \times B)$ of a n-simplex of $K \star (A \times B)$. Then

$$\phi : A \times (K \star B) \coprod_{A \times K} K \longrightarrow K \star (A \times B)$$

is a categorical equivalence.

Proof. Recall [10, Proposition 4.2.1.2] that there is a map

$$\eta_{X,Y} : X \diamond Y = X \coprod_{X \times Y \times \{0\}} X \times Y \times \Delta^1 \coprod_{X \times Y \times \{1\}} Y \longrightarrow X \star Y$$

natural in X and Y which is always a categorical equivalence. Thus

$$f = (A \times \eta_{K,B}) \sqcup \mathrm{id}_K : A \times (K \diamond B) \coprod_{A \times K} K \longrightarrow A \times (K \star B) \coprod_{A \times K} K$$

is a categorical equivalence. The domain is isomorphic to $K \diamond (A \times B)$, and it is easy to check that the map $\eta_{K, A\times B}$ is the composite

$$K \diamond (A \times B) \xrightarrow{f} A \times (K \star B) \coprod_{A \times K} K \xrightarrow{\phi} K \star (A \times B).$$

Using the 2 out of 3 property of the categorical equivalences, we deduce that ϕ is a categorical equivalence. □

4.22. **Lemma.** *For all $L \in s\mathbf{Set}^+_{/S}$, we have a natural equivalence*

$$\phi : \mathrm{Fun}_S(L, {}_\natural C_{(p,S)/}) \xrightarrow{\simeq} \mathrm{Fun}_{K//S}(K \star_S (L \times_S \mathcal{O}(S)^\sharp), {}_\natural C).$$

Proof. Define bisimplicial sets $X, Y : \Delta^{op} \longrightarrow s\mathbf{Set}$ by

$$\begin{aligned}X_n &= \mathrm{Map}_{K//S}(K \star_S ((\Delta^n)^\flat \times L \times_S \mathcal{O}(S)^\sharp), {}_\natural C)\\ Y_n &= \mathrm{Map}(\Delta^n, \mathrm{Fun}_{K//S}(K \star_S (L \times_S \mathcal{O}(S)^\sharp), {}_\natural C))\\ &\cong \mathrm{Map}_{K//S}((\Delta^n)^\flat \times (K \star_S (L \times_S \mathcal{O}(S)^\sharp) \coprod_{(\Delta^n)^\flat \times K} K, {}_\natural C).\end{aligned}$$

and define a map of bisimplicial sets $\Phi : X \longrightarrow Y$ by precomposing levelwise by the map

$$g_{L,n} : (\Delta^n)^\flat \times (K \star_S (L \times_S \mathcal{O}(S)^\sharp)) \coprod_{(\Delta^n)^\flat \times K} K \longrightarrow K \star_S ((\Delta^n)^\flat \times L \times_S \mathcal{O}(S)^\sharp)$$

adjoint as a map over $S \times \Delta^1$ to the identity over $S \times \partial\Delta^1$. Taking levelwise zero simplices then defines the map ϕ, which is clearly natural in L, K, and C. By Theorem 4.16, taking a fibrant replacement of K we may suppose that K is fibrant. We first check that X and Y are complete Segal spaces. By [9, Theorem 4.12], Y is a complete Segal space as it arises from a ∞-category. For X, since $\mathrm{Map}_{K//S}(-,-)$ is a right Quillen bifunctor, we only have to observe that:

- Every monomorphism $A \longrightarrow B$ of simplicial sets induces a cofibration

$$K \star_S (A^\flat \times L \times_S \mathcal{O}(S)^\sharp) \longrightarrow K \star_S (B^\flat \times L \times_S \mathcal{O}(S)^\sharp)$$

so X is Reedy fibrant.

- The spine inclusion $\iota_n : \mathrm{Sp}(n) \longrightarrow \Delta^n$ induces a trivial cofibration
$$K \star_S (\mathrm{Sp}(n)^\flat \times L \times_S \mathcal{O}(S)^\sharp) \longrightarrow K \star_S ((\Delta^n)^\flat \times L \times_S \mathcal{O}(S)^\sharp);$$
ι_n is inner anodyne, so this follows from Theorem 4.15 and [10, Proposition 3.1.4.2].
- The map $\pi : E \longrightarrow \Delta^0$ where E is the nerve of the contractible groupoid with two elements induces a cocartesian equivalence
$$K \star_S (E^\flat \times L \times_S \mathcal{O}(S)^\sharp) \longrightarrow K \star_S (L \times_S \mathcal{O}(S)^\sharp);$$
$\pi^\flat$ is a cocartesian equivalence (as the composite of $E^\flat \longrightarrow E^\sharp$ and $E^\sharp \longrightarrow \Delta^0$), so this also follows from Theorem 4.15 and [10, Proposition 3.1.4.2].

We next prove that Φ is an equivalence in the complete Segal model structure. For this, we will prove that each map $g_{L,n}$ is a cocartesian equivalence in $s\mathbf{Set}^+_{/S}$. Both sides preserves colimits as a functor of L (valued in $s\mathbf{Set}^+_{K//S}$), so by left properness and the stability of cocartesian equivalences under filtered colimits we reduce to the case L is an m-simplex with some marking. In particular, $(\Delta^m)^\flat \times_S \mathcal{O}(S)^\sharp \longrightarrow S$ is fibrant in $s\mathbf{Set}^+_{/S}$. By [10, Theorem 4.2.4.1] we may check that the square of fibrant objects

$$\begin{array}{ccc}
(\Delta^n)^\flat \times K & \longrightarrow & K \\
\downarrow & & \downarrow \\
(\Delta^n)^\flat \times (K \star_S ((\Delta^m)^\flat \star_S \mathcal{O}(S)^\sharp)) & \longrightarrow & K \star_S ((\Delta^n)^\flat \times (\Delta^m)^\flat \times_S \mathcal{O}(S)^\sharp)
\end{array}$$

is a homotopy pushout square in the underlying ∞-category $\mathbf{Cat}^{cocart}_{\infty,S} \simeq \mathrm{Fun}(S, \mathbf{Cat}_\infty)$, where colimits are computed objectwise. In other words, we may check that for every $s \in S$, the fiber of the square over s is a homotopy pushout square in $s\mathbf{Set}$, which holds by Lemma 4.21. Pushing out along the cofibration $(\Delta^m)^\flat \times_S \mathcal{O}(S)^\sharp \longrightarrow L \times_S \mathcal{O}(S)^\sharp$ and using left properness, we deduce that $g_{L,m}$ is a cocartesian equivalence. Finally, we invoke [9, Theorem 4.11] to deduce that ϕ is a categorical equivalence. □

4.23. **Lemma.** *Let $L \longrightarrow S$ be a cocartesian fibration. Then* $\mathrm{id}_K \star \iota_L : K \star_S {}_\natural L \longrightarrow K \star_S ({}_\natural L \times_S \mathcal{O}(S)^\sharp)$ *is a cocartesian equivalence in $s\mathbf{Set}^+_{/S}$.*

Proof. By Theorem 4.16, taking a fibrant replacement of K we may suppose that K is fibrant. By Proposition 13.4, it suffices to show that for every $s \in S$, $K^\sim_s \star L^\sim_s \longrightarrow K^\sim_s \star ({}_\natural L \times_S (S^{/s})^\sharp)$ is a marked equivalence in $s\mathbf{Set}^+$. Observe that the *cartesian* equivalence $\{s\} \longrightarrow (S^{/s})^\sharp$ pulls back by the cocartesian fibration ${}_\natural L \longrightarrow S^\sharp$ to a marked equivalence $L^\sim_s \longrightarrow {}_\natural L \times_S (S^{/s})^\sharp$. Then by Theorem 4.15 for $S = \Delta^0$, $K^\sim_s \star -$ preserves marked equivalences, which concludes the proof. □

4.24. **Notation.** Suppose we have a commutative square of S-categories and S-functors

$$\begin{array}{ccc}
K & \xrightarrow{G} & D \\
\downarrow{\scriptstyle F} & & \downarrow{\scriptstyle \pi} \\
C & \xrightarrow{\rho} & M.
\end{array}$$

Define $\underline{\mathrm{Fun}}_{K//M,S}(C,D)$ to be the pullback

$$\begin{array}{ccc}
\underline{\mathrm{Fun}}_{K//M,S}(C,D) & \longrightarrow & \underline{\mathrm{Fun}}_S(C,D) \\
\downarrow & & \downarrow{\scriptstyle (F^*,\pi_*)} \\
S & \xrightarrow{\sigma_{\pi G}} & \underline{\mathrm{Fun}}_S(K,M).
\end{array}$$

If $K = \emptyset$, we will also denote $\underline{\mathrm{Fun}}_{K//M,S}(C,D)$ as $\underline{\mathrm{Fun}}_{/M,S}(C,D)$. If $M = S$, we will write $\underline{\mathrm{Fun}}_{K//S}(C,D)$ in place of $\underline{\mathrm{Fun}}_{K//S,S}(C,D)$.

Note that by Proposition 3.8 and Proposition 2.16, the defining pullback square is a homotopy pullback square if F is a monomorphism and π is a categorical fibration.

4.25. **Proposition.** *Let K, L, C be S-categories and let $p : K \longrightarrow C$, $q : L \longrightarrow C$ be S-functors.*

(1) We have an equivalence

$$\psi : \underline{\mathrm{Fun}}_S(L, C_{(p,S)/}) \xrightarrow{\simeq} \underline{\mathrm{Fun}}_{K//S}(K \star_S L, C).$$

(2) We have an equivalence

$$\psi' : \underline{\mathrm{Fun}}_S(L, C_{/(q,S)}) \xrightarrow{\simeq} \underline{\mathrm{Fun}}_{L//S}(K \star_S L, C)$$

(3) We have equivalences

$$\underline{\mathrm{Fun}}_{/C,S}(L, C_{(p,S)/}) \xrightarrow[\simeq]{\psi_q} \underline{\mathrm{Fun}}_{K \sqcup L//S}(K \star_S L, C) \xleftarrow[\simeq]{\psi'_p} \underline{\mathrm{Fun}}_{/C,S}(K, C_{/(q,S)}).$$

Proof. (1) Define the S-functor ψ as follows: suppose given a marked simplicial set A and a map $A \longrightarrow \underline{\mathrm{Fun}}_S(L, C_{(p,S)/})$ over S. This is equivalently given by the datum of a map

$$f_A : {}_\natural K \star_S ((A \times_S \mathcal{O}(S)^\sharp \times_S {}_\natural L) \times_S \mathcal{O}(S)^\sharp) \longrightarrow {}_\natural C$$

under K and over S. Let

$${}_\natural K \coprod_{A \times_S \mathcal{O}(S)^\sharp \times_S {}_\natural K} (A \times_S \mathcal{O}(S)^\sharp) \times_S ({}_\natural K \star_S ({}_\natural L \times_S \mathcal{O}(S)^\sharp)) \longrightarrow K \star_S (A \times_S \mathcal{O}(S)^\sharp \times_S {}_\natural L \times_S \mathcal{O}(S)^\sharp)$$

be the map over $S \times \Delta^1$ adjoint to the identity over $S \times \partial\Delta^1$. Precomposing f_A by this and $\iota_L : {}_\natural L \longrightarrow {}_\natural L \times_S \mathcal{O}(S)^\sharp$ on that factor defines the desired map $A \longrightarrow \underline{\mathrm{Fun}}_{K//S}(K \star_S L, C)$.

Now to check that ψ is an equivalence, we may work fiberwise and combine Lemma 4.22 and Lemma 4.23.

(2) This follows by a parallel argument to the proof of (1).

(3) We prove that ψ_q is an equivalence; a parallel argument will work for ψ'_p. $\underline{\mathrm{Fun}}_{K \sqcup L//S}(K \star_S L, C)$ fits into a diagram

$$\begin{array}{ccccc}
\underline{\mathrm{Fun}}_{K \sqcup L//S}(K \star_S L, C) & \longrightarrow & \underline{\mathrm{Fun}}_{K//S}(K \star_S L, C) & \longrightarrow & \underline{\mathrm{Fun}}_S(K \star_S L, C) \\
\downarrow & & \downarrow & & \downarrow \\
S & \longrightarrow & \underline{\mathrm{Fun}}_{K//S}(K \coprod L, C) & \longrightarrow & \underline{\mathrm{Fun}}_S(K \coprod L, C) \\
 & & \downarrow & & \downarrow \\
 & & S & \xrightarrow{\sigma_p} & \underline{\mathrm{Fun}}_S(K, C)
\end{array}$$

in which every square is a pullback square. The map ψ_q is then defined to be the pullback of the map of spans

$$\begin{array}{ccccc}
\underline{\mathrm{Fun}}_S(L, C_{(p,S)/}) & \longrightarrow & \underline{\mathrm{Fun}}_S(L, C) & \xleftarrow{\sigma_q} & S \\
\downarrow \psi & & \downarrow p \sqcup - & & \downarrow = \\
\underline{\mathrm{Fun}}_{K//S}(K \star_S L, C) & \longrightarrow & \underline{\mathrm{Fun}}_{K//S}(K \coprod L, C) & \longleftarrow & S
\end{array}$$

in which the vertical arrows are equivalences. By Proposition 4.19 and $\underline{\mathrm{Fun}}_S(L, -)$ being right Quillen, the top left horizontal arrow is a S-fibration, and by Proposition 3.8, the bottom left horizontal arrow is a S-fibration. It follows that ψ_q is an equivalence.

□

In light of Proposition 4.25, we have evident 'alternative' S-slice S-categories, whose definition more closely adheres to the intuition that a slice category is a category of extensions.

4.26. **Definition.** Let $p : K \longrightarrow C$ be a S-functor. We define the *alternative S-undercategory*

$$C^{(p,S)/} := \underline{\mathrm{Fun}}_{K//S}(K \star_S S, C).$$

Similarly, we define the *alternative S-overcategory*

$$C^{/(p,S)} := \underline{\mathrm{Fun}}_{K//S}(S \star_S K, C).$$

4.27. **Corollary.** *Let $p : K \longrightarrow C$ and $q : L \longrightarrow C$ be S-functors.*

(1) We have equivalences $C_{(p,S)/} \xrightarrow{\simeq} C^{(p,S)/}$ *and* $C_{/(q,S)} \xrightarrow{\simeq} C^{/(q,S)}$.
(2) We have an equivalence $\underline{\mathrm{Fun}}_{/C,S}(L, C^{(p,S)/}) \simeq \underline{\mathrm{Fun}}_{/C,S}(K, C^{/(q,S)})$ *through a natural zig-zag.*

Proof. For (1), let $L = S$ and $K = S$ in Proposition 4.25(1) and (2), respectively. For (2), combine the preceding (1) and Proposition 4.25(3). □

4.28. **Warning.** When $S = \Delta^0$, the alternative S-undercategory $C^{(p,S)/} \cong \{p\} \times_{\mathrm{Fun}(K,C)} \mathrm{Fun}(K^{\rhd}, C)$ differs from Lurie's alternative undercategory $C^{p/}$. However, we have a comparison functor

$$\{p\} \times_{\mathrm{Fun}(K,C)} \mathrm{Fun}(K^{\rhd}, C) \longrightarrow C^{p/}$$

which is a categorical equivalence and which factors through the categorical equivalence $C_{p/} \longrightarrow C^{p/}$ of [10, Proposition 4.2.1.5].

Slicing over and under S-points. We give a smaller model for slicing over and under S-points in an S-category C.

4.29. **Notation.** Suppose C an S-category. Let

$$\mathcal{O}_S(C) := \widetilde{\mathrm{Fun}}_S(S \times \Delta^1, C) \cong S \times_{\mathcal{O}(S)} \mathcal{O}(C)$$

denote the fiberwise arrow S-category of C. Given an object $x \in C$, let

$$C^{/\underline{x}} := \mathcal{O}_S(C) \times_C \underline{x}\,, \quad C^{\underline{x}/} := \underline{x} \times_C \mathcal{O}_S(C).$$

4.30. **Proposition.** *Let $x \in C$ be an object and denote by $i_x : \underline{x} \longrightarrow C_{\underline{x}}$ the $\underline{x}$-functor defined by x. We have natural equivalences of $\underline{x}$-categories*

$$C_{\underline{x}}{}^{/(\underline{x}, i_x)} \simeq C^{/\underline{x}}$$
$$C_{\underline{x}}{}^{/(i_x, \underline{x})} \simeq C^{\underline{x}/}.$$

Proof. For any functor $S' \longrightarrow S$ and S-category C, $\mathcal{O}_S(C) \times_S S' \cong \mathcal{O}_{S'}(C \times_S S')$. Therefore, $\mathcal{O}_S(C) \times_C \underline{x} \cong \mathcal{O}_{\underline{x}}(C_{\underline{x}}) \times_{C_{\underline{x}}} \underline{x}$ and likewise for $\underline{x} \times_C \mathcal{O}_S(C)$. Changing base to $\underline{x}$, we may suppose $S = \underline{x}$ and $i_x = i : S \longrightarrow C$ is any S-functor. The identity section $S \longrightarrow \mathcal{O}(S)$ induces a morphism of spans

$$\begin{array}{ccccc} S & \xrightarrow{\sigma_i} & \underline{\mathrm{Fun}}_S(S, C) & \longleftarrow & \underline{\mathrm{Fun}}_S(S \times \Delta^1, C) \\ \downarrow {=} & & \downarrow & & \downarrow \\ S & \xrightarrow{i} & C & \longleftarrow & \widetilde{\mathrm{Fun}}_S(S \times \Delta^1, C) \end{array}$$

with the vertical maps equivalences. Taking pullbacks now yields the claim (where we use the isomorphism $S \star_S S \cong S \times \Delta^1$ to identify the upper pullback with the S-slice category in question). □

4.31. **Proposition.** *We have a natural equivalence $C^{\underline{x}/} \simeq C^{x/}$ of left fibrations over C.*

Proof. Using the marked left anodyne map ${}_\natural\Lambda^2_1 \longrightarrow {}_\natural\Delta^2$ and the map of Lemma 2.23 for $n = 2$, we obtain a span

$$\mathrm{Fun}((\Delta^{\{0,1\}})^\sharp, {}_\natural C) \times_{C^{\{1\}}} \mathrm{Fun}(\Delta^{\{1,2\}}, C) \overset{\simeq}{\twoheadleftarrow} \mathrm{Fun}({}_\natural\Delta^2, {}_\natural C) \overset{\simeq}{\twoheadrightarrow} \mathrm{Fun}(\Delta^{\{0,2\}}, C) \times_{S^{\{0,2\}}} \mathrm{Fun}(\Delta^2, S).$$

Pulling back via $\{x\} \times_{C^{\{0\}}} -$ on the left and $- \times_{S^{\{1,2\}}} S$ on the right, and using that the inclusion $\Delta^{\{0,2\}} \longrightarrow \Delta^2 \cup_{\Delta^{\{1,2\}}} \Delta^0$ is a categorical equivalence, we get

$$C^{\underline{x}/} \overset{\simeq}{\twoheadleftarrow} \{x\} \times_{C^{\{0\}}} \mathrm{Fun}({}_\natural\Delta^2, {}_\natural C) \times_{S^{\{1,2\}}} S \overset{\simeq}{\twoheadrightarrow} C^{x/}.$$

□

5. Limits and colimits

In this section, we introduce S-colimits and study their basic properties. We then study the correspondence between S-colimits and S-limits through the vertical opposite construction of [4].

5.1. **Definition.** Let C be a S-category and $\sigma : S \longrightarrow C$ be a cocartesian section. We say that σ is a S-*initial object* if $\sigma(s)$ is an initial object for all objects $s \in S$. Dually, σ is a S-*final object* if $\sigma(s)$ is a final object for all $s \in S$.

5.2. **Definition.** Let K and C be S-categories. Let $\overline{p} : K \star_S S \longrightarrow C$ be an extension of a S-functor $p : K \longrightarrow C$. From the commutativity of the diagram

$$\begin{array}{ccc} S & \xrightarrow{\sigma_{\overline{p}}} & \underline{\mathrm{Fun}}_S(K \star_S S, C) \\ \downarrow{=} & & \downarrow \\ S & \xrightarrow{\sigma_p} & \underline{\mathrm{Fun}}_S(K, C) \end{array}$$

(recall Notation 3.5 for $\sigma_{(-)}$) we see that $\sigma_{\overline{p}}$ defines a cocartesian section of $C^{(p,S)/}$ (Definition 4.26), which we also denote by $\sigma_{\overline{p}}$. We say that $\overline{p}$ is a S-*colimit diagram* if $\sigma_{\overline{p}}$ is a S-initial object. If $\overline{p}$ is a S-colimit diagram, then $\overline{p}|_S : S \longrightarrow C$ is said to be a S-*colimit* of p. If S admits an initial object s, we will also identify the S-colimit with its value on s.

Dually, substituting $S \star_S K$ for $K \star_S S$ leads in a parallel way to the definition of an S-*limit diagram* and an S-*limit*.

5.3. **Remark.** In view of the comparison result Corollary 4.27, we could also use the S-slice category $C_{(p,S)/}$ to make the definition of a S-colimit diagram. This would yield some additional generality, in that $C_{(p,S)/}$ is defined for an arbitrary marked simplicial set K. However, the construction $C^{(p,S)/}$ is easier to relate to functor categories, which we need to do to show that the left adjoint to the restriction along $K \subset K \star_S S$ computes colimits (a special case of Corollary 9.16).

5.4. **Remark.** Suppose K and C are ∞-categories, and write $\pi : K \longrightarrow *$ for the map to a point. One may define the K-indexed colimit 'globally' as the (partially defined) left adjoint $\pi_!$ to the restriction functor $\pi^* : C \longrightarrow \mathrm{Fun}(K, C)$. Given a diagram $p : K \longrightarrow C$ that admits an extension to a colimit diagram $\overline{p} : K^{\rhd} \longrightarrow C$ with cone point $\{v\}$, one then has $\overline{p}|_{\{v\}} \simeq \pi_!(p)$.

To establish a parallel picture for S-colimits, we will first need to introduce the concept of S-adjunctions (Definition 8.3). If we now let K and C be S-categories and $\pi : K \longrightarrow S$ denote the structure map, we will show that if for all $s \in S$, $C_{\underline{s}}$ admits $K_{\underline{s}}$-indexed $S^{s/}$-colimits, then the restriction S-functor $\pi^* : C \longrightarrow \underline{\mathrm{Fun}}_S(K, C)$ admits a left S-adjoint $\pi_!$ such that

$$(\pi_!)_s : \mathrm{Fun}_{S^{s/}}(K_{\underline{s}}, C_{\underline{s}}) \longrightarrow C_s$$

computes the $S^{s/}$-colimit (Theorem 10.5 in the special case $\phi = \pi$). Furthermore, taking cocartesian sections of this S-adjunction then yields an adjunction, which we may abusively denote as

$$\pi_! : \mathrm{Fun}_S(K, C) \rightleftarrows \mathrm{Fun}_S(S, C) : \pi_*,$$

in which $\pi_!$ computes the S-colimit.

In proving some of the assertions in this subsection (Corollary 5.9, Proposition 5.11, and Proposition 5.12), it will be convenient to have this relationship between S-colimits and S-adjunctions established. We note that there is no danger of circularity here since the proof of Theorem 10.5 (or its simpler predecessor Theorem 9.15) doesn't use any of the remainder of this subsection (which, apart from S-(co)limits in an S-category of S-objects, is only devoted to working out special classes of diagrams in the theory).

There are a couple instances where the notion of S-colimit specializes to a notion of ordinary category theory. For example, we have the following pair of propositions computing S-colimits and S-limits in an S-category of objects $\underline{C}_S$ as left or right Kan extensions in C; the asymmetry in their formulations arises due to working with *cocartesian* fibrations instead of cartesian fibrations to model S-categories. In the statements, recall Notation 3.11 for the meaning of $(-)^{\dagger}$.

5.5. **Proposition.** *Let $\overline{p} : K \star_S S \longrightarrow \underline{C}_S$ be a S-functor extending $p : K \longrightarrow \underline{C}_S$. Suppose further that a left Kan extension of $p^\dagger : K \longrightarrow C$ to a functor $K \star_S S \longrightarrow C$ exists. Then the following are equivalent:*

(1) $\overline{p}$ is a S-colimit diagram.
(2) $\overline{p}^\dagger$ is a left Kan extension of $p^\dagger$.
(3) $\overline{p}^\dagger|_{K_s^\rhd}$ is a colimit diagram for all $s \in S$.

Proof. (2) and (3) are equivalent because left Kan extensions along cocartesian fibrations are computed fiberwise. Suppose (3). To prove (1), we want to show that for every $s \in S$, $\overline{p}_{\underline{s}}$ is an initial object in $((\underline{C}_S)^{(p,S)/})_s$. But $((\underline{C}_S)^{(p,S)/})_s$ is equivalent to the fiber of $\mathrm{Fun}(K_{\underline{s}} \star_{\underline{s}} \underline{s}, C) \longrightarrow \mathrm{Fun}(K_{\underline{s}}, C)$ over $p^\dagger|_{K_{\underline{s}}}$, so to prove the claim it suffices to show that the functor $\overline{p}^\dagger|_{K_{\underline{s}}}$ is a left Kan extension of $p|_{K_{\underline{s}}}$. This holds by the equivalence of (2) and (3) for $S^{s/}$.

Conversely, suppose (1). Since we supposed that a left Kan extension of $p^\dagger$ exists, left Kan extensions of $p^\dagger|_{K_s}$ all exist and *any* initial object in the fiber of $\mathrm{Fun}(K_{\underline{s}} \star_{\underline{s}} \underline{s}, C) \longrightarrow \mathrm{Fun}(K_{\underline{s}}, C)$ over $p^\dagger|_{K_{\underline{s}}}$ is a left Kan extension of $p^\dagger|_{K_{\underline{s}}}$, necessarily a fiberwise colimit diagram (we need this hypothesis because Kan extensions as defined in [10, §4.3.2] are always *pointwise* Kan extensions). This implies (3). □

5.6. **Proposition.** *Let $\overline{p} : S \star_S K \longrightarrow \underline{C}_S$ be a S-functor extending $p : K \longrightarrow \underline{C}_S$. Suppose further that a right Kan extension of $p^\dagger : K \longrightarrow C$ to a functor $S \star_S K \longrightarrow C$ exists. Then the following are equivalent:*

(1) $\overline{p}$ is a S-limit diagram.
(2) $\overline{p}^\dagger$ is a right Kan extension of $p^\dagger$.
(2') $\overline{p}^\dagger|_{\underline{s} \star_{\underline{s}} K_{\underline{s}}}$ is a right Kan extension of $p^\dagger|_{K_{\underline{s}}}$ for all $s \in S$.
(3) $\overline{p}^\dagger|_{K_{\underline{s}}^\lhd}$ is a limit diagram for all $s \in S$.

Proof. We first observe that because the inclusion $S \longrightarrow S \star_S K$ is left adjoint to the structure map $S \star_S K \longrightarrow S$ of the cocartesian fibration,

$$(S \star_S K)^{s/} \simeq S^{s/} \times_S (S \star_S K) \cong \underline{s} \star_{\underline{s}} K_{\underline{s}}.$$

The equivalence of (2) and (2') now follows from the formula for a right Kan extension. Also, if we view $K_{\underline{s}}^\lhd$ as mapping to $S \star_S K$ via $\{s\} \star K_{\underline{s}} \longrightarrow \underline{s} \star_{\underline{s}} K_{\underline{s}} \longrightarrow S \star_S K$ where the first map is adjoint to $(\{s\} \longrightarrow \underline{s}, \mathrm{id})$, then (2) and (3) are also equivalent by the same argument. Finally, (2') implies (1) by definition, and (1) implies (2') under our additional assumption that a right Kan extension of $p^\dagger$ exists (for the same reason as given in the proof of Proposition 5.5). □

If S is a Kan complex, then the notion of S-colimit reduces to the usual notion of colimit.

5.7. **Proposition.** *Let S be a Kan complex. Then a S-functor $\overline{p} : K \star_S S \longrightarrow C$ is a S-colimit diagram if and only if for every object $s \in S$, $\overline{p}|_s : (K_s)^\rhd \longrightarrow C_s$ is a colimit diagram.*

Proof. If S is a Kan complex, then for every $s \in S$, $S^{s/}$ is a contractible Kan complex. Therefore, for all $s \in S$ we have $(C^{(p,S)/})_s \simeq \{p_s\} \times_{\mathrm{Fun}(K_s, C_s)} \mathrm{Fun}(K_s^\rhd, C_s)$, which proves the claim. □

We say that K is a *constant* S-category if it is equivalent to $S \times L$ for L an ∞-category. We have an isomorphism $L^\rhd \times S \longrightarrow (L \times S) \star_S S$ (defined as a map over $S \times \Delta^1$ to be the adjoint to the identity on $(L \times S, S)$).

5.8. **Proposition.** *A S-functor $\overline{p} : L^\rhd \times S \longrightarrow C$ is a S-colimit diagram if and only if for every object $s \in S$, $\overline{p}_s : L^\rhd \longrightarrow C_s$ is a colimit diagram.*

Proof. Observe that

$$(C^{(p,S)/})_s = \{p_{\underline{s}}\} \times_{\mathrm{Fun}_{S^{s/}}(L \times S^{s/}, C_{\underline{s}})} \mathrm{Fun}_{S^{s/}}(L^\rhd \times S^{s/}, C_{\underline{s}}) \simeq \{p_s\} \times_{\mathrm{Fun}(L, C_s)} \mathrm{Fun}(L^\rhd, C_s).$$

Therefore, $\sigma_{\overline{p}} : S \longrightarrow C^{(p,S)/}$ is S-initial if and only if for all $s \in S$, $\{\overline{p}_s\} \in \{p_s\} \times_{\mathrm{Fun}(L, C_s)} \mathrm{Fun}(L^\rhd, C_s)$ is an initial object, which is the claim. □

5.9. **Corollary.** *Suppose C is a S-category such that C_s admits all colimits for every object $s \in S$ and the pushforward functors $\alpha_! : C_s \longrightarrow C_t$ preserve all colimits for every morphism $\alpha : s \to t$ in S. Then C admits all S-colimits indexed by constant diagrams.*

Proof. First suppose that S has an initial object s. Suppose that $p : L \times S \longrightarrow C$ is a S-functor. Let $\overline{p_s} : L^{\rhd} \longrightarrow C_s$ be a colimit diagram extending p_s. Let $\overline{p} : L^{\rhd} \times S \longrightarrow C$ be a S-functor corresponding to $\overline{p_s}$ under the equivalence $\mathrm{Fun}_S(L^{\rhd} \times S, C) \simeq \mathrm{Fun}(L^{\rhd}, C_s)$, which we may suppose extends p. By Proposition 5.8, $\overline{p}$ is a S-colimit diagram.

The general case now follows from Theorem 9.15, taking $\phi : C \longrightarrow D$ to be $L \times S \longrightarrow S$. □

We now turn to the example of corepresentable fibrations.

5.10. **Definition.** Let $s \in S$ be an object and let K be an $S^{s/}$-category which is equivalent to a coproduct of corepresentable fibrations

$$\coprod_{i \in I} S^{\alpha_i/} \simeq \coprod_{i \in I} S^{t_i/} \xrightarrow{\coprod \alpha_i^*} S^{s/}$$

for $\{\alpha_i : s \to t_i\}_{i \in I}$ a collection of morphisms in S. Let $p : K \longrightarrow C \times_S S^{s/}$ be a $S^{s/}$-functor, so p is precisely the data of objects $\{x_i \in C_{t_i}\}_{i \in I}$. Let $\overline{p} : K \star_{S^{s/}} S^{s/} \longrightarrow C \times_S S^{s/}$ be a $S^{s/}$-colimit diagram extending p, and let $y = \overline{p}(v) \in C_s$ for $v = \mathrm{id}_s$ the cone point. Then we say that y is the *S-coproduct* of $\{x_i\}_{i \in I}$ along $\{\alpha_i\}_{i \in I}$, and we adopt the notation $y = \coprod_{\alpha_i} x_i$.

Our choice of terminology is guided by the following result, which shows that a $S^{s/}$-colimit of a $S^{s/}$-functor $p : S^{\alpha/} \simeq S^{t/} \longrightarrow C$ obtains the value of a left adjoint to the pushforward functor $\alpha_!$ on $p(t)$. In the case of $S = \mathbf{O}_G^{op}$, $C = \underline{\mathbf{Spc}}_G$ or $\underline{\mathbf{Sp}}^G$, and $K = \mathbf{O}_H^{op}$, this is the induction or indexed coproduct functor from H to G.

5.11. **Proposition.** *Let C be a S-category, let $\alpha : s \to t$ be a morphism in C, and let $\pi : M \longrightarrow \Delta^1$ be a* ***cartesian*** *fibration classified by the pushforward functor $\alpha_! : C_s \longrightarrow C_t$. Let $p : S^{t/} \longrightarrow C \times_S S^{s/}$ be a $S^{s/}$-functor and let $x = p(\mathrm{id}_t) \in C_t$. Then the data of a $S^{s/}$-colimit diagram extending p yields a π-cocartesian edge e in M with $d_0(e) = x$ and lifting $0 \to 1$.*

Proof. Let $\overline{p} : S^{t/} \star_{S^{s/}} S^{s/} \longrightarrow C \times_S S^{s/}$ be a $S^{s/}$-colimit diagram extending p. Let $y = \overline{p}(\mathrm{id}_s)$ and let $f' : \Delta^1 \longrightarrow S^{t/} \star_{S^{s/}} S^{s/}$ be the edge connecting id_t to α. We may suppose that M is given by the relative nerve of $\alpha_!$, so that edges in M over Δ^1 are given by commutative squares

$$\begin{array}{ccc} \{1\} & \longrightarrow & C_s \\ \downarrow & & \downarrow{\scriptstyle \alpha_!} \\ \Delta^1 & \longrightarrow & C_t. \end{array}$$

Then let e be the edge in M determined by y and $f = \overline{p} \circ f' : x \to \alpha_! y$. By definition, $d_0(e) = x$.

We claim that e is π-cocartesian. This holds if and only if for every $y' \in C_s$ the map

$$\mathrm{Map}_{C_s}(y, y') \longrightarrow \mathrm{Map}_{C_t}(x, \alpha_! y')$$

induced by f is an equivalence. But the local variant of the adjunction of Theorem 10.5 implies this (passing to global sections). □

S-coproducts also satisfy a base-change condition. This is awkward to articulate in general, because the pullback of a corepresentable fibration along another need not be corepresentable. However, if we impose the additional hypothesis that $T = S^{op}$ admits multipullbacks, then a pullback of a corepresentable fibration decomposes as a finite coproduct of corepresentable fibrations. In this case, we have the following useful reformulation of the base-change condition. Recall from the introduction that we let $\mathbf{F}_T$ denote the finite coproduct completion of T. Let $X \subset \mathcal{O}(\mathbf{F}_T)$ be the full subcategory on those arrows whose source lies in T and consider the span

$$(\mathbf{F}_T)^{\sharp} \xleftarrow{\mathrm{ev}_1} {}_{\natural}X \xrightarrow{\mathrm{ev}_0} T^{\sharp}.$$

This satisfies the dual of the hypotheses of Theorem 2.24, so

$$C^{\times} := (\mathrm{ev}_0)_* (\mathrm{ev}_1)^* ((C^{\vee})^{\natural})$$

is a cartesian fibration over $\mathbf{F}_T$ (with the cartesian edges marked), where $C^\vee \longrightarrow T$ is the dual cartesian fibration of [4]. Unwinding the definitions, given a finite T-set $U = \coprod_i s_i$, we have that the fiber

$$(C^\times)_U \simeq \mathrm{Fun}_T(\coprod_i T^{/s_i}, C^\vee) \simeq \prod_i C_{s_i}$$

(where $\mathrm{Fun}_T(-,-)$ denotes those functors over T that preserve cartesian edges), and given a morphism of T-sets $\alpha : U \longrightarrow V$, the pullback functor $\alpha^* : (C^\times)_U \longrightarrow (C^\times)_V$ is induced by restriction.

5.12. **Proposition.** *C admits finite S-coproducts if and only if $\pi : C^\times \longrightarrow \mathbf{F}_T$ is a **Beck-Chevalley fibration**, i.e. π is both cocartesian and cartesian, and for every pullback square*

$$\begin{array}{ccc} W & \xrightarrow{\alpha'} & V' \\ \downarrow{\scriptstyle \beta'} & & \downarrow{\scriptstyle \beta} \\ U & \xrightarrow{\alpha} & V \end{array}$$

in $\mathbf{F}_T$, the natural transformation

$$(*) \qquad (\alpha')_!(\beta')^* \longrightarrow \beta^* \alpha_!$$

adjoint to the equivalence $(\beta')^*\alpha^* \simeq (\alpha')^*\beta^*$ is itself an equivalence.

Proof. By Theorem 10.5, C admits finite S-coproducts if and only if for every finite collection of morphisms $\{\alpha_i : s \to t_i\}$, the restriction functor

$$(\coprod \alpha_i)^* : \underline{\mathrm{Fun}}_S(S^{s/}, C) \longrightarrow \underline{\mathrm{Fun}}_S(\coprod_i S^{t_i/}, C)$$

admits a left S-adjoint, in which case that left S-adjoint is computed by the S-coproduct along the α_i. This in turn is immediately equivalent to π being additionally cocartesian and $(*)$ being an equivalence for $\alpha = \coprod \alpha_i : \coprod t_i \to s$ and all morphisms $\beta : s' \to s$ in T. Finally, note that the apparently more general case of $(*)$ being an equivalence for any pullback square is actually determined by this, because any map $\alpha : U = \coprod t_i \to V = \coprod s_j$ is the data of $f : I \to J$ and $\{\alpha_{ij} : s_j \to t_i\}_{i \in f^{-1}(j)}$, whence $\alpha^* = (\alpha_{ij})^* : \prod_j C_{s_j} \longrightarrow \prod_i C_{t_i}$, etc. yields a decomposition of the map $(*)$ in terms of the 'basic' squares that we already handled. □

We conclude this subsection by introducing a bit of useful terminology.

5.13. **Definition.** Let C be a S-category. We say that C is *S-cocomplete* if, for every object $s \in S$ and $S^{s/}$-diagram $p : K \longrightarrow C_{\underline{s}}$ (with K fiberwise small), p admits a $S^{s/}$-colimit.

5.14. **Remark.** Suppose that E is S-cocomplete. Then taking $D = S$ in Theorem 9.15, E admits all (small) S-colimits. However, the converse may fail: if we suppose that E admits all S-colimits, then any $S^{s/}$-diagram $K_{\underline{s}} \longrightarrow E_{\underline{s}}$ pulled back from a S-diagram $K \longrightarrow E$ admits a $S^{s/}$-colimit; however, not every $S^{s/}$-diagram need be of this form.

Vertical opposites. In this subsection we study the vertical opposite construction of [4], with the goal of justifying our intuition that the theory of S-limits can be recovered from that of S-colimits, and vice-versa (Corollary 5.25). We first recall the definition of the twisted arrow ∞-category from [1, §2].

5.15. **Definition.** Given a simplicial set X, we define $\widetilde{\mathcal{O}}(X)$ to be the simplicial set whose n-simplices are given by the formula

$$\widetilde{\mathcal{O}}(X)_n := \mathrm{Hom}((\Delta^n)^{op} \star \Delta^n, X).$$

If X is an ∞-category, then $\widetilde{\mathcal{O}}(X)$ is the twisted arrow ∞-category of X.

5.16. **Warning.** By definition, $\widetilde{\mathcal{O}}(X)$ comes equipped with a source functor $\mathrm{ev}_0 : \widetilde{\mathcal{O}}(X) \longrightarrow X^{op}$ and a target functor $\mathrm{ev}_1 : \widetilde{\mathcal{O}}(X) \longrightarrow X$. In other words, twisted arrows are *contravariant* in the source and *covariant* in the target. This convention is opposite to that in [12], but agrees with [4].

5.17. **Recollection.** Suppose $X \longrightarrow T$ a cocartesian fibration. Then the simplicial set X^{vop} is defined to have n-simplices

$$\begin{array}{ccc} {}_\natural\widetilde{\mathcal{O}}(\Delta^n) & \longrightarrow & {}_\natural X \\ {\scriptstyle \mathrm{ev}_1}\downarrow & & \downarrow \\ (\Delta^n)^\sharp & \longrightarrow & T^\sharp. \end{array}$$

The forgetful map $X^{vop} \longrightarrow T$ is a cocartesian fibration with cocartesian edges given by $\widetilde{\mathcal{O}}(\Delta^1)^\sharp \longrightarrow {}_\natural X$. For every $t \in T$, we have an equivalence $(X_t)^{op} \xrightarrow{\simeq} (X^{vop})_t$ implemented by the map which precomposes by $\mathrm{ev}_0 : {}_\natural\widetilde{\mathcal{O}}(\Delta^n) \longrightarrow ((\Delta^n)^{op})^\flat$, which is an equivalence in $s\mathbf{Set}^+$.

Dually, suppose $Y \longrightarrow T$ a cartesian fibration. Then the simplicial set Y^{vop} is defined to have n-simplices

$$\begin{array}{ccc} (\widetilde{\mathcal{O}}(\Delta^n)^{op})^\natural & \longrightarrow & Y^\natural \\ {\scriptstyle \mathrm{ev}_0^{op}}\downarrow & & \downarrow \\ (\Delta^n)^\sharp & \longrightarrow & T^\sharp. \end{array}$$

and similarly the forgetful map $Y^{vop} \longrightarrow T$ is a cartesian fibration with fibers $(Y^{vop})_t \xleftarrow{\simeq} (Y_t)^{op}$. As a warning, note that the definition of the underlying simplicial set of $(-)^{vop}$ changes depending on whether the input is a cocartesian or cartesian fibration; in particular, the notation is potentially ambiguous for a bicartesian fibration. We will not apply $(-)^{vop}$ to bicartesian fibrations in this paper.

Define a functor $\widetilde{\mathcal{O}}'(-) : s\mathbf{Set}^+_{/S} \longrightarrow s\mathbf{Set}^+_{/S}$ by

$$\widetilde{\mathcal{O}}'(A \xrightarrow{\pi} S) = (\widetilde{\mathcal{O}}(A), \mathcal{E}_A) \xrightarrow{\pi \circ \mathrm{ev}_1} S$$

where an edge e is in $\mathcal{E}_A$ just in case $\mathrm{ev}_0(e)$ is marked in A^{op}. Note that $\widetilde{\mathcal{O}}(-)$ preserves colimits since it is defined as precomposition by $\Delta^{op} \xrightarrow{(rev \star \mathrm{id})^{op}} \Delta^{op}$, and from this it easily follows that $\widetilde{\mathcal{O}}'(-)$ also preserves colimits. By the adjoint functor theorem, $\widetilde{\mathcal{O}}'(-)$ admits a right adjoint, which we label $(-)^{vop}$; this agrees with the previously defined $(-)^{vop}$ for cocartesian fibrations ${}_\natural X \longrightarrow S^\sharp$.

5.18. **Proposition.** *The adjunction*

$$\widetilde{\mathcal{O}}'(-) \colon s\mathbf{Set}^+_{/S} \rightleftarrows s\mathbf{Set}^+_{/S} : (-)^{vop}$$

is a Quillen equivalence with respect to the cocartesian model structure on $s\mathbf{Set}^+_{/S}$.

Proof. We first prove the adjunction is Quillen by employing the criterion of Lemma 4.13. Consider the four classes of maps which generate the left marked anodyne maps:

(1) $i : \Lambda^n_k \hookrightarrow \Delta^n$, $0 < k < n$: By [1, Lemma 12.15], $\widetilde{\mathcal{O}}(\Lambda^n_k) \hookrightarrow \widetilde{\mathcal{O}}(\Delta^n)$ is inner anodyne, so $\widetilde{\mathcal{O}}'(i)$ is left marked anodyne.
(2) $i : {}_\natural\Lambda^n_0 \hookrightarrow {}_\natural\Delta^n$: We can adapt the proof of [1, Lemma 12.16] to show that $\widetilde{\mathcal{O}}'(i)$ is a cocartesian equivalence in $s\mathbf{Set}^+_{/S}$ (even though it fails to be left marked anodyne). The basic fact underlying this is that a *right* marked anodyne map is an equivalence in $s\mathbf{Set}^+$, so in $s\mathbf{Set}^+_{/S}$ if it lies entirely over an object; details are left to the reader.
(3) $i : K^\flat \hookrightarrow K^\sharp$ for K a Kan complex: Because $\widetilde{\mathcal{O}}(K) \longrightarrow K^{op} \times K$ is a left fibration, $\widetilde{\mathcal{O}}(K)$ is then again a Kan complex. It follows that $\widetilde{\mathcal{O}}'(i)$ is left marked anodyne.
(4) $(\Lambda^2_1)^\sharp \cup_{\Lambda^2_1} (\Delta^2)^\flat \hookrightarrow (\Delta^2)^\sharp$: Obvious from the definitions.

It remains to show that for a trivial cofibration $f : {}_\natural X \hookrightarrow {}_\natural Y$ between fibrant objects, $\widetilde{\mathcal{O}}'(f)$ is again a trivial cofibration. Since $\widetilde{\mathcal{O}}(X) \longrightarrow \widetilde{\mathcal{O}}(Y)$ is a map of cocartesian fibrations over S and the marking on $\widetilde{\mathcal{O}}'(-)$ contains these cocartesian edges, by Proposition 13.4 it suffices to show that for every object

$s \in S$, $\widetilde{\mathcal{O}}'(X)_s \longrightarrow \widetilde{\mathcal{O}}'(Y)_s$ is an equivalence in $s\mathbf{Set}^+$. We have a commutative square

$$\begin{array}{ccc} \widetilde{\mathcal{O}}'(X)_s & \longrightarrow & \widetilde{\mathcal{O}}'(Y)_s \\ \downarrow & & \downarrow \\ X_s^\sharp & \xrightarrow{f_s} & Y_s^\sharp \end{array}$$

where the vertical maps are left fibrations and the bottom map is an equivalence in $s\mathbf{Set}^+$. Therefore, the map $X_s^\sharp \times_{Y_s^\sharp} \widetilde{\mathcal{O}}'(Y)_s \longrightarrow \widetilde{\mathcal{O}}'(Y)_s$ is an equivalence in $s\mathbf{Set}^+$. Applying Proposition 13.4 once more, we reduce to showing that for every object $x_1 \in X$, $\widetilde{\mathcal{O}}'(X)_{x_1} \longrightarrow \widetilde{\mathcal{O}}'(Y)_{f(x_1)}$ is an equivalence in $s\mathbf{Set}^+$.

Now employing the source maps, we have a commutative square

$$\begin{array}{ccc} \widetilde{\mathcal{O}}'(X)_{x_1} & \longrightarrow & \widetilde{\mathcal{O}}'(Y)_{f(x_1)} \\ \downarrow & & \downarrow \\ X^{op\natural} & \xrightarrow{f^{op}} & Y^{op\natural} \end{array}$$

where the vertical maps are left fibrations and the bottom horizontal map is a *cartesian* equivalence in $s\mathbf{Set}^+_{/S^{op}}$. Therefore, the map $X^{op} \times_{Y^{op}} \widetilde{\mathcal{O}}'(Y)_s \longrightarrow \widetilde{\mathcal{O}}'(Y)_s$ is a cartesian equivalence. By a third application of Proposition 13.4, we reduce to showing that for every object $x_0 \in X$, $\widetilde{\mathcal{O}}'(X)_{(x_0,x_1)} \longrightarrow \widetilde{\mathcal{O}}'(Y)_{(f(x_0),f(x_1))}$ is an equivalence. But now both sides are endowed with the maximal marking and the map is equivalent to $\mathrm{Map}_X(x_0,x_1) \xrightarrow{f_*} \mathrm{Map}_Y(f(x_0),f(x_1))$, which is an equivalence by assumption.

The fact that this Quillen adjunction is an equivalence follows immediately from [4, Theorem 1.4]. □

5.19. **Lemma.** *Let $C \longrightarrow S$ be a cocartesian fibration.*

(1) Let $f : S' \longrightarrow S$ be a functor. Then we have an isomorphism $f^*(C^{vop}) \cong f^*(C)^{vop}$.
(2) Let $g : S \longrightarrow T$ be a cartesian fibration and let C be a S-category. Then there is a T-functor $\chi : g_*(C)^{vop} \longrightarrow g_*(C^{vop})$ natural in C which is an equivalence.

Proof. (1) is obvious from the definitions. For (2), the map χ is defined as follows: an n-simplex of $g_*(C)^{vop}$ over $\sigma \in T_n$ is given by the data of a commutative diagram

$$\begin{array}{ccc} {}_\natural\widetilde{\mathcal{O}}(\Delta^n) \times_{T^\sharp} S^\sharp & \longrightarrow & {}_\natural C \\ \downarrow & & \downarrow \\ (\Delta^n \times_T S)^\sharp & \xrightarrow{g^*\sigma} & S^\sharp \end{array}$$

and precomposition by the obvious map $\widetilde{\mathcal{O}}(\Delta^n \times_T S) \longrightarrow \widetilde{\mathcal{O}}(\Delta^n) \times_T S$ yields an n-simplex of $g_*(C^{vop})$.

We now show that for all $t \in T$, χ_t is a categorical equivalence. Because χ_t is obtained by taking levelwise 0-simplices of the map of complete Segal spaces

$$\mathrm{Map}_S({}_\natural\widetilde{\mathcal{O}}(\Delta^\bullet) \times S_t^\sharp, {}_\natural C) \longrightarrow \mathrm{Map}_S({}_\natural\widetilde{\mathcal{O}}(\Delta^\bullet) \times \widetilde{\mathcal{O}}(S_t)^\sharp, {}_\natural C),$$

it suffices to show that for all n, ${}_\natural\widetilde{\mathcal{O}}(\Delta^n) \times \widetilde{\mathcal{O}}(S_t)^\sharp \longrightarrow {}_\natural\widetilde{\mathcal{O}}(\Delta^n) \times S_t^\sharp$ is a cocartesian equivalence in $s\mathbf{Set}^+_{/S}$. As a special case of Proposition 6.3, $\widetilde{\mathcal{O}}(S_t)^\sharp \longrightarrow S_t^\sharp$ is a cocartesian equivalence in $s\mathbf{Set}^+_{/S_t}$, so the claim follows. □

5.20. **Lemma.** *The map* $\mathrm{ev}^{op} : (\widetilde{\mathcal{O}}(\Delta^n)^{op})^\natural \longrightarrow (\Delta^n)^\sharp \times ((\Delta^n)^{op})^\flat$ *is left marked anodyne.*

Proof. For convenience, we will relabel $\widetilde{\mathcal{O}}(\Delta^n)^{op}$ as the nerve of the poset I_n with objects ij, $0 \le i \le j \le n$ and maps $ij \longrightarrow kl$ for $i \le k$ and $j \le l$. Then an edge $ij \to kl$ is marked in I_n just in case $j = l$, and the map ev^{op} becomes the projection $\rho_n : I_n \longrightarrow (\Delta^n)^\sharp \times (\Delta^n)^\flat$, $ij \mapsto (i,j)$. Let $f_n : (\Delta^n)^\flat \longrightarrow I_n$ be the map which sends i to $0i$. Then $\rho_n \circ f_n : \{0\} \times (\Delta^n)^\flat \longrightarrow (\Delta^n)^\sharp \times (\Delta^n)^\flat$ is left marked anodyne, so by the right cancellativity of left marked anodyne maps it suffices to show that i_n is left marked anodyne. For this, we factor f_n as the composition

$$(\Delta^n)^\flat = I_{n,-1} \longrightarrow I_{n,0} \longrightarrow \dots \longrightarrow I_{n,n} = I_n$$

where $I_{n,k} \subset I_n$ is the subcategory on objects ij, $i = 0$ or $j \leq k$ (and inherits the marking from I_n), and argue that each inclusion $g_k : I_{n,k} \subset I_{n,k+1}$ is left marked anodyne. For this, note that g_k fits into a pushout square

$$\begin{array}{ccc} \{0\} \times (\Delta^{k+1})^\flat \bigcup_{\{0\}\times(\Delta^k)^\flat} (\Delta^{n-k-1})^\sharp \times (\Delta^k)^\flat & \longrightarrow & (\Delta^{n-k-1})^\sharp \times (\Delta^{k+1})^\flat \\ \downarrow & & \downarrow \\ I_{n,k} & \xrightarrow{g_k} & I_{n,k+1} \end{array}$$

with the upper horizontal map marked left anodyne. □

5.21. **Construction.** Suppose T an ∞-category, $X, Z \longrightarrow T$ cocartesian fibrations, $Y \longrightarrow T$ a cartesian fibration, and a map $\mu : {}_\natural X \times_T Y^\natural \longrightarrow {}_\natural Z$ of marked simplicial sets over T. We define a map

$$\mu^{vop} : {}_\natural X^{vop} \times_T Y^{vop\natural} \longrightarrow {}_\natural Z^{vop}$$

by the following process:

Let J_n be the nerve of the poset with objects ij, $0 \leq i \leq n$, $-n \leq j \leq n$ and $-j \leq i$ and maps $ij \to kl$ if $i \leq k$, $j \leq l$. Mark edges $ij \longrightarrow kl$ if $j = l$. Let $I_n \subset J_n$ be the subcategory on ij with $j \geq 0$ and $I'_n \subset J_n$ be the subcategory on ij with $j \leq 0$; also give I_n, I'_n the induced markings. We have an inclusion $(\Delta^n)^\sharp \longrightarrow J_n$ given by $i \mapsto i0$ which restricts to inclusions $(\Delta^n)^\sharp \longrightarrow I_n$, $(\Delta^n)^\sharp \longrightarrow I'_n$ and induces a map $\gamma_n : I_n \cup_{(\Delta^n)^\sharp} I'_n \subset J_n$.

Define auxiliary (unmarked) simplicial sets $Z' \longrightarrow T$ by $\mathrm{Hom}_{/T}(\Delta^n, Z') = \mathrm{Hom}_{/T}(J_n, {}_\natural Z)$ and $Z'' \longrightarrow T$ by $\mathrm{Hom}_{/T}(\Delta^n, Z'') = \mathrm{Hom}_{/T}(I_n \cup_{(\Delta^n)^\sharp} I'_n, {}_\natural Z)$, where $J_n \longrightarrow \Delta^n$ via $ij \mapsto i$. We have a map $r : Z' \longrightarrow Z''$ given by restriction along the γ_n, which we claim is a trivial fibration. By a standard reduction, for this it suffices to show that γ_n is left marked anodyne. Indeed, this follows from Lemma 5.20 applied to $I_n \longrightarrow (\Delta^n)^\sharp \times \Delta^n$ and the observation that the map $\Delta^n \times \Delta^n \cup_{\Delta^n} I'_n \longrightarrow J_n$ is inner anodyne, whose proof we leave to the reader.

Define also a map $Z' \longrightarrow Z^{vop}$ over T by restriction along the map ${}_\natural\widetilde{\mathcal{O}}(\Delta^n) \longrightarrow J_n$ which sends ij to jn if $i = 0$ and $j(-i)$ otherwise. Finally, define a map $X^{vop} \times_T Y^{vop} \longrightarrow Z''$ over T as follows: a map $\Delta^n \longrightarrow X^{vop} \times_T Y^{vop}$ is given by the data

$$\begin{array}{ccc} {}_\natural\widetilde{\mathcal{O}}(\Delta^n) & \longrightarrow & {}_\natural X \\ \downarrow & & \downarrow \\ (\Delta^n)^\sharp & \longrightarrow & T^\sharp \end{array} , \quad \begin{array}{ccc} \left(\widetilde{\mathcal{O}}(\Delta^n)^{op}\right)^\natural & \longrightarrow & Y^\natural \\ \downarrow & & \downarrow \\ (\Delta^n)^\sharp & \longrightarrow & T^\sharp. \end{array}$$

We have isomorphisms ${}_\natural\widetilde{\mathcal{O}}(\Delta^n) \cong I'_n$ and $\left(\widetilde{\mathcal{O}}(\Delta^n)^{op}\right)^\natural \cong I_n$, and obvious retractions $I_n \cup_{(\Delta^n)^\sharp} I'_n \longrightarrow I_n, I'_n$ given by collapsing the complementary part onto Δ^n. Using this, we may define

$$I_n \cup_{(\Delta^n)^\sharp} I'_n \longrightarrow {}_\natural X \times_T Y^\natural \longrightarrow {}_\natural Z$$

which is an n-simplex of Z''.

Choosing a section of r, we may compose these maps to define μ^{vop}, which is then easily checked to also preserve the indicated markings. For example, μ^{vop} on edges is given by

$$\left(\begin{array}{ccc} & & x_{11} \\ & & \downarrow \\ x_{00} & \longrightarrow & x_{01}, \\ & & \\ y_{01} & \longrightarrow & y_{11} \\ \downarrow & & \\ y_{00} & & \end{array}\right) \mapsto \left(\begin{array}{ccc} & & \mu(x_{11}, y_{11}) \\ & & \downarrow \\ \mu(x_{00}, y_{01}) & \longrightarrow & \mu(x_{01}, y_{11}) \\ \downarrow & & \downarrow \\ \mu(x_{00}, y_{00}) & \longrightarrow & \alpha_! \mu(x_{00}, y_{00}) \end{array}\right) \mapsto \left(\begin{array}{ccc} & & \mu(x_{11}, y_{11}) \\ & & \downarrow \\ \mu(x_{00}, y_{00}) & \longrightarrow & \alpha_! \mu(x_{00}, y_{00}) \end{array}\right)$$

where $\alpha_! \mu(x_{00}, y_{00})$ is a choice of pushforward for the edge α in T that the diagrams are vertically over.

5.22. **Lemma.** *Let $C \longrightarrow T$ be a cartesian fibration and let $D \longrightarrow T$ be a cocartesian fibration. There exists a T-equivalence $\psi : \widetilde{\mathrm{Fun}}_T(C, D)^{vop} \longrightarrow \widetilde{\mathrm{Fun}}_T(C^{vop}, D^{vop})$.*

Proof. We have a map $\mu : \widetilde{\mathrm{Fun}}_T(C, D) \times_T C \longrightarrow D$ adjoint to the identity. Employing Construction 5.21 on μ and then adjointing, we obtain our desired T-functor ψ. A chase of the definitions then shows that for all objects $t \in T$, ψ_t is homotopic to the known equivalence $\mathrm{Fun}(C_t, D_t)^{op} \simeq \mathrm{Fun}(C_t^{op}, D_t^{op})$. □

5.23. **Lemma.** *Let K and L be S-categories. Then there exists a S-equivalence*

$$\psi : (K \star_S L)^{vop} \xrightarrow{\simeq} L^{vop} \star_S K^{vop}$$

over $S \times \Delta^1$.

Proof. Note that $(S \times \Delta^1)^{vop} \cong S \times (\Delta^1)^{op}$. View $(K \star_S L)^{vop}$ as lying over $S \times \Delta^1$ via the isomorphism $(\Delta^1)^{op} \cong \Delta^1$. Since $(K \star_S L)_0^{vop} \cong L^{vop}$ and $(K \star_S L)_1^{vop} \cong K^{vop}$, we have our S-functor ψ as adjoint to the identity over $S \times \partial \Delta^1$. Fiberwise, ψ_s is homotopic to the known isomorphism $(K_s \star L_s)^{op} \cong L_s^{op} \star K_s^{op}$, so ψ is an equivalence. □

5.24. **Proposition.** *Suppose S-categories K and C.*

(1) The adjoint of the vertical opposite of the evaluation map induces a equivalence

$$\underline{\mathrm{Fun}}_S(K, C)^{vop} \xrightarrow{\simeq} \underline{\mathrm{Fun}}_S(K^{vop}, C^{vop}).$$

(2) Suppose a S-functor $p : K \longrightarrow C$. We have equivalences

$$(C^{(p,S)/})^{vop} \simeq (C^{vop})^{/(p^{vop}, S)}, \quad (C^{/(p,S)})^{vop} \simeq (C^{vop})^{(p^{vop}, S)/}.$$

Proof. (1) Recall from 6.3.1 the equivalence $\underline{\mathrm{Fun}}_S(K, C) \simeq \pi_* \pi'^* \{K, C\}_S$. By Lemma 5.22 and Lemma 5.19(1),

$$\{K, C\}_S^{vop} \simeq \{K^{vop}, C^{vop}\}_S.$$

By Lemma 5.19(1) and (2),

$$\pi_* \pi'^* \{K, C\}_S^{vop} \simeq (\pi_* \pi'^* \{K, C\}_S)^{vop}.$$

Combining these equivalences supplies an equivalence $\underline{\mathrm{Fun}}_S(K, C)^{vop} \simeq \underline{\mathrm{Fun}}_S(K^{vop}, C^{vop})$. It is straightforward but tedious to verify that the adjoint of the vertical opposite of the evaluation map $\underline{\mathrm{Fun}}_S(K, C)^{vop} \times_S K^{vop} \longrightarrow C^{vop}$ is homotopic to this equivalence.

(2) Combine (1), Lemma 5.23, Proposition 5.18 (which shows in particular that $(-)^{vop}$ is right Quillen), and the definition of the S-slice category.

□

5.25. **Corollary.** *Let $\overline{p} : S \star_S K \longrightarrow C$ be a S-functor. Then $\overline{p}$ is a S-limit diagram if and only if $\overline{p}^{vop} : K^{vop} \star_S S \longrightarrow C^{vop}$ is a S-colimit diagram.*

This allows us to deduce statements about S-limits from statements about S-colimits, and vice-versa. For this reason, we will primarily concentrate our attention on proving statements concerning S-colimits (and eventually, S-left Kan extensions), leaving the formulation of the dual results to the reader.

5.26. **Warning.** Even with Corollary 5.25, it seems difficult to deduce Proposition 5.6 concerning S-limits in an S-category of objects $\underline{C}_S$ directly from Proposition 5.5 on S-colimits in $\underline{C}_S$. This is because the formation of vertical opposites $\underline{C}_S \mapsto (\underline{C}_S)^{vop}$ doesn't intertwine with any operation at the level of the ∞-category C.

6. Assembling S-slice categories from ordinary slice categories

Suppose a S-functor $p : K \longrightarrow C$. For every morphism $\alpha : s \to t$ in S, we have a functor $p_\alpha : K_s \longrightarrow C_t$, and we may consider the collection of 'absolute' slice categories $C_{p_\alpha/}$ and examine the functoriality that they satisfy. For this, we have the following basic observation: given a morphism $f : t \to t'$, *covariant* functoriality of slice categories in the target yields a functor $C_{p_\alpha/} \longrightarrow C_{p_{f\alpha}/}$, and given a morphism $g : s' \to s$, *contravariant* functoriality in the source yields a functor $C_{p_\alpha/} \longrightarrow C_{p_{\alpha g}/}$. Elaborating, we will show in this section that there exists a functor

$$F := F(p : K \longrightarrow C) : \widetilde{\mathcal{O}}(S) \longrightarrow \mathbf{Cat}_\infty$$

out of the twisted arrow category $\widetilde{\mathcal{O}}(S)$ such that $F(\alpha) \simeq C_{p_\alpha/}$, which encodes all of this functoriality (Definition 6.5). Moreover, the right Kan extension of F along the target functor $\widetilde{\mathcal{O}}(S) \longrightarrow S$ is $C_{(p,S)/}$ (Theorem 6.6). We will end with some applications of this result to the theory of cofinality and presentability (Theorem 6.7 and Remark 6.11).

We first record a cofinality result which implies that the values of a right Kan extension along $\mathrm{ev}_1 : \widetilde{\mathcal{O}}(S) \longrightarrow S$ are computed as ends.

6.1. **Lemma.** *The functor $\widetilde{\mathcal{O}}(S^{s/}) \longrightarrow \widetilde{\mathcal{O}}(S) \times_S S^{s/}$ is initial.*

Proof. Let $(\alpha : u \longrightarrow t, \beta : s \longrightarrow t)$ be an object of $\widetilde{\mathcal{O}}(S) \times_S S^{s/}$. We will prove that

$$C = \widetilde{\mathcal{O}}(S^{s/}) \times_{\widetilde{\mathcal{O}}(S) \times_S S^{s/}} (\widetilde{\mathcal{O}}(S) \times_S S^{s/})_{/(\alpha,\beta)}$$

is weakly contractible. An object of C is the data of an edge

$$\begin{array}{ccc} & s & \\ {}^{f}\swarrow & & \searrow^{g} \\ x & \xrightarrow{h} & y \end{array}$$

in $S^{s/}$, which we will abbreviate as $f \xrightarrow{h} g$, and an edge

$$\left(\begin{array}{ccc} x & \xrightarrow{h} & y \\ {}^{\delta}\uparrow & & \downarrow^{\gamma} \\ u & \xrightarrow{\alpha} & t \end{array} , \quad \begin{array}{ccc} s & \xrightarrow{g} & y \\ & {}_{\beta}\searrow & \downarrow^{\gamma} \\ & & t \end{array} \right)$$

in $\widetilde{\mathcal{O}}(S) \times_S S^{s/}$, which we will abbreviate as $(h, g) \xrightarrow{(\delta,\gamma)} (\alpha, \beta)$.

Let $C_0 \subset C$ be the full subcategory on objects $c = ((f \xrightarrow{h} g), (h, g) \xrightarrow{(\delta,\gamma)} (\alpha, \beta))$ such that γ is a degenerate edge in $S^{s/}$. We will first show that C_0 is a reflective subcategory of C by verifying the first condition of [10, Proposition 5.2.7.8]. Given an object c of C, define c' to be $((f \xrightarrow{\gamma h} \beta), (\gamma h, \beta) \xrightarrow{(\delta,\mathrm{id}_t)} (\alpha, \beta))$ and let $e : c \longrightarrow c'$ be the edge given by

$$\left(\begin{array}{ccc} f & \xrightarrow{h} & g \\ {}^{\mathrm{id}_f}\uparrow & & \downarrow^{\gamma} \\ f & \xrightarrow{\gamma h} & \beta \end{array} , \quad \begin{array}{ccc} (h,g) & \xrightarrow{(\mathrm{id}_x,\gamma)} & (\gamma h, \beta) \\ & {}_{(\delta,\gamma))}\searrow \quad \swarrow_{(\delta,\mathrm{id}_t))} & \\ & (\alpha,\beta) & \end{array} \right).$$

We need to show that for all $d = ((f' \xrightarrow{h'} \beta), (h', \beta) \xrightarrow{(\delta',\mathrm{id})} (\alpha, \beta)) \in C_0$, $\mathrm{Map}_C(c', d) \xrightarrow{e^*} \mathrm{Map}_C(c, d)$ is a homotopy equivalence. The space $\mathrm{Map}_C(c, d)$ lies in a commutative diagram

$$\begin{array}{ccc} \mathrm{Map}_C(c,d) & \longrightarrow & \mathrm{Map}_{\widetilde{\mathcal{O}}(S^{s/})}(f \xrightarrow{h} g, f' \xrightarrow{h'} \beta) \\ \downarrow & & \downarrow \\ \mathrm{Map}_{(\widetilde{\mathcal{O}}(S) \times_S S^{s/})_{/(\alpha,\beta)}}((h,g),(h',\beta)) & \longrightarrow & \mathrm{Map}_{\widetilde{\mathcal{O}}(S) \times_S S^{s/}}((h,g),(h',\beta)) \\ \downarrow & & \downarrow{\scriptstyle (\delta',\mathrm{id})_*} \\ \Delta^0 & \xrightarrow{(\delta,\gamma)} & \mathrm{Map}_{\widetilde{\mathcal{O}}(S) \times_S S^{s/}}((h,g),(\alpha,\beta)) \end{array}$$

where the two squares are homotopy pullback squares. We also have the analogous diagram for $\mathrm{Map}_C(c', d)$, and the map e^* is induced by a natural transformation of these diagrams. The assertion then reduces to checking that the upper square in the diagram

$$\begin{array}{ccc}
\mathrm{Map}_{\widetilde{\mathcal{O}}(S^{s/})}(f \xrightarrow{\gamma h} \beta, f' \xrightarrow{h'} \beta) & \xrightarrow{(\mathrm{id}_f, \gamma)^*} & \mathrm{Map}_{\widetilde{\mathcal{O}}(S^{s/})}(f \xrightarrow{h} g, f' \xrightarrow{h'} \beta) \\
\downarrow & & \downarrow \\
\mathrm{Map}_{\widetilde{\mathcal{O}}(S) \times_S S^{s/}}((\gamma h, \beta), (\alpha, \beta)) & \xrightarrow{(\mathrm{id}_x, \gamma))^*} & \mathrm{Map}_{\widetilde{\mathcal{O}}(S) \times_S S^{s/}}((h, g), (\alpha, \beta)) \\
\downarrow & & \downarrow \\
\mathrm{Map}_{S^{s/}}(\beta, \beta) & \xrightarrow{\gamma^*} & \mathrm{Map}_{S^{s/}}(g, \beta)
\end{array}$$

is a homotopy pullback square. Since (id_x, γ) and (id_f, γ) are ev_1-cocartesian edges in $\widetilde{\mathcal{O}}(S)$ and $\widetilde{\mathcal{O}}(S^{s/})$ respectively, the lower and outer squares are homotopy pullback squares (where we implicitly use that the map (δ', id) covers the identity in $S^{s/}$ to identify the long vertical maps with those induced by ev_1), and the claim is proven.

To complete the proof, we will show that $c = (\beta = \beta, (\mathrm{id}_t, \beta) \xrightarrow{(\alpha, \mathrm{id}_t)} (\alpha, \beta))$ is an initial object in C_0. Let $d \in C_0$ be as above. In the diagram

$$\begin{array}{ccccc}
\Delta^0 & \xrightarrow{(h', \mathrm{id}_\beta)} & \mathrm{Map}_{\widetilde{\mathcal{O}}(S^{s/})}(\beta = \beta, f' \xrightarrow{h'} \beta) & & \\
\downarrow & & \downarrow & & \\
\Delta^0 & \xrightarrow{(\alpha, \mathrm{id}_t)} & \mathrm{Map}_{\widetilde{\mathcal{O}}(S) \times_S S^{s/}}((\mathrm{id}_t, \beta), (\alpha, \beta)) & \longrightarrow & \mathrm{Map}_{\widetilde{\mathcal{O}}(S)}(\mathrm{id}_t, \alpha) \\
\downarrow & & \downarrow & & \downarrow \\
\Delta^0 & \xrightarrow{\mathrm{id}_\beta} & \mathrm{Map}_{S^{s/}}(\beta, \beta) & \longrightarrow & \mathrm{Map}_S(t, t)
\end{array}$$

we need to show that the upper square is a homotopy pullback square in order to prove that $\mathrm{Map}_C(c, d) \simeq *$. The fiber of $\widetilde{\mathcal{O}}(S)$ over $t \in S$ is equivalent to $(S_{/t})^{op}$; in particular, id_t is an initial object in the fiber over t. Therefore, the two outer squares are both homotopy pullbacks. Since the lower right square is a homotopy pullback, this shows that all squares in the diagram are homotopy pullbacks, as desired. □

Let K be an S-category. Let J_n be the poset with objects ij for $0 \leq i \leq j \leq 2n+1$ which has a unique morphism $ij \longrightarrow kl$ if and only if $k \leq i \leq j \leq l$. Let $I_n \subset J_n$ be the full subcategory on objects ij such that $i \leq n$. In view of the isomorphisms

$$J_n \cong \widetilde{\mathcal{O}}(\Delta^{2n+1}) \cong \widetilde{\mathcal{O}}((\Delta^n)^{op} \star \Delta^n),$$

the I_n and J_n extend to functors

$$I_\bullet \subset J_\bullet \cong \widetilde{\mathcal{O}}((\Delta^\bullet)^{op} \star \Delta^\bullet) : \Delta \longrightarrow s\mathbf{Set}.$$

Viewing I_n and J_n as marked simplicial sets where $ij \longrightarrow kl$ is marked just in case $k = i$, we moreover have functors to $s\mathbf{Set}^+$. Define the simplicial set $X : \Delta^{op} \longrightarrow \mathbf{Set}$ to be the functor

$$\mathrm{Hom}_{s\mathbf{Set}^+}(I_\bullet, \natural K) \times_{\mathrm{Hom}(I_\bullet, S)} \mathrm{Hom}((\Delta^\bullet)^{op} \star \Delta^\bullet, S)$$

where $I_\bullet \subset J_\bullet \longrightarrow (\Delta^\bullet)^{op} \star \Delta^\bullet$ is given by the target map. An n-simplex of X is thus the data of a diagram

$$\begin{array}{ccccccccccccc}
 & & & & & & k_{nn} & \longrightarrow & k_{n(n+1)} & \longrightarrow & \dots & \longrightarrow & k_{n(2n+1)} \\
 & & & & & & \downarrow & & \downarrow & & & & \downarrow \\
 & & \iddots & & & & \vdots & & \vdots & & \dots & & \vdots \\
 & & k_{11} & \longrightarrow & \dots & \longrightarrow & k_{1n} & \longrightarrow & k_{1(n+1)} & \longrightarrow & \dots & \longrightarrow & k_{1(2n+1)} \\
 & & \downarrow & & & & \downarrow & & \downarrow & & & & \downarrow \\
k_{00} & \longrightarrow & k_{01} & \longrightarrow & \dots & \longrightarrow & k_{0n} & \longrightarrow & k_{0(n+1)} & \longrightarrow & \dots & \longrightarrow & k_{0(2n+1)}
\end{array}$$

where the horizontal edges are cocartesian in K and the vertical edges lie over degeneracies in S.

Declare an edge e in X to be marked if the corresponding map $I_1 \longrightarrow {}_\natural K$ sends all edges to marked edges. We have a commutative square of marked simplicial sets

$$\begin{array}{ccc}
X & \longrightarrow & \widetilde{\mathcal{O}}(S)^\sharp \\
\downarrow & & \downarrow{\scriptstyle \mathrm{ev}_0} \\
(K^\vee)^\natural & \longrightarrow & (S^{op})^\sharp
\end{array}$$

where $K^\vee = (K^{vop})^{op} \longrightarrow S^{op}$ is the dual cartesian fibration and the map $X \longrightarrow K^\vee$ is defined by restricting $I_n \longrightarrow K$ to $I'_n \longrightarrow K$ (where I'_n is the full subcategory of I_n on ij with $j \leq n$). Let ψ denote the resulting map from X to the pullback.

6.2. **Lemma.** $\psi : X \longrightarrow (K^\vee)^\natural \times_{(S^{op})^\sharp} \widetilde{\mathcal{O}}(S)^\sharp$ *is a trivial fibration of marked simplicial sets.*

Proof. Since any lift of a marked edge in $(K^\vee)^\natural \times_{(S^{op})^\sharp} \widetilde{\mathcal{O}}(S)^\sharp$ to an edge in X is marked, it suffices to prove that the underlying map of simplicial sets is a trivial fibration.

We first show that $I'_n \subset I_n$ is left marked anodyne. Let $I_{n,k} \subset I_n$ be the full subcategory on objects ij with $i \leq k$ and similarly for $I'_{n,k}$. For $0 \leq k < n$ we have a pushout decomposition

$$\begin{array}{ccc}
((\Delta^{n-k})^{op})^\flat \times (\Delta^k)^\sharp \displaystyle\bigcup_{((\Delta^{n-k-1})^{op})^\flat \times (\Delta^k)^\sharp} ((\Delta^{n-k-1})^{op})^\flat \times (\Delta^{n+k+1})^\sharp & \longrightarrow & I'_{n,n-k} \displaystyle\bigcup_{I'_{n,n-k-1}} I_{n,n-k-1} \\
\downarrow & & \downarrow \\
((\Delta^{n-k})^{op})^\flat \times (\Delta^{n+k+1})^\sharp & \longrightarrow & I_{n,n-k},
\end{array}$$

and the lefthand map is left marked anodyne by [10, Proposition 3.1.2.3]. It thus suffices to show that

$$I'_{n,0} \cong (\Delta^n)^\sharp \longrightarrow I_{n,0} \cong (\Delta^{2n+1})^\sharp$$

is left marked anodyne, and this is clear.

We now explain how to solve the lifting problem

$$\begin{array}{ccc}
\partial\Delta^n & \longrightarrow & X \\
\downarrow & \nearrow & \downarrow \\
\Delta^n & \longrightarrow & K^\vee \times_{S^{op}} \widetilde{\mathcal{O}}(S).
\end{array}$$

To supply the dotted arrow we must provide a lift in the commutative square

$$\begin{array}{ccc}
\partial I_n \cup_{\partial I'_n} I'_n & \longrightarrow & {}_\natural K \\
\downarrow{\scriptstyle f} & \nearrow & \downarrow \\
I_n & \longrightarrow & S^\sharp.
\end{array}$$

where $\partial I_n = \bigcup_{[n-1]\subset[n]} I_{n-1}$ as a simplicial subset of I_n and likewise for $\partial I'_n$. Then since $I'_n \longrightarrow \partial I_n \cup_{\partial I'_n} I'_n$ and $I'_n \longrightarrow I_n$ are left marked anodyne, f is a cocartesian equivalence in $s\mathbf{Set}^+_{/S}$, and the lift exists. $\square$

For all $s \in S$, we have trivial cofibrations $i_s : K_s \xrightarrow{\simeq} (K^\vee)_s$, and thus commutative squares

$$\begin{array}{ccc} K_s & \xrightarrow{\mathrm{id}_s} & \widetilde{\mathcal{O}}(S) \\ \big\downarrow & & \big\downarrow{\scriptstyle \mathrm{ev}_0} \\ K^\vee & \longrightarrow & S^{op}. \end{array}$$

From this we obtain a cofibration

$$\iota : \coprod_{s\in S} K_s \hookrightarrow K^\vee \times_{S^{op}} \widetilde{\mathcal{O}}(S).$$

We have an explicit lift ι' of ι to X, where $K_s \longrightarrow X$ is given by precomposition by $I_n \longrightarrow \Delta^n$, $ij \mapsto n-i$.

By Lemma 6.2, there exists a lift σ in the commutative square

$$\begin{array}{ccc} \coprod_{s\in S} K_s & \xrightarrow{\iota'} & X \\ \big\downarrow{\scriptstyle \iota} & \overset{\sigma}{\nearrow} & \big\downarrow{\scriptstyle \psi} \\ K^\vee \times_{S^{op}} \widetilde{\mathcal{O}}(S) & \xrightarrow{=} & K^\vee \times_{S^{op}} \widetilde{\mathcal{O}}(S). \end{array}$$

Let $\chi : X \longrightarrow K$ be the functor induced by $\Delta^n \longrightarrow I_n$, $i \mapsto (n-i)(n+i)$. Define the *twisted pushforward*

$$\widetilde{P} : K^\vee \times_{S^{op}} \widetilde{\mathcal{O}}(S) \longrightarrow K$$

to be the map over S given by the composite $\chi \circ \sigma$. Then for every object $\alpha : s \longrightarrow t$ in $\widetilde{\mathcal{O}}(S)$, $\widetilde{P}_\alpha \circ i_s : K_s \longrightarrow K_t$ is a choice of pushforward functor over α, which is chosen to be the identity if $\alpha = \mathrm{id}_s$.

6.3. **Proposition.** *For all $A \in s\mathbf{Set}_{/S}$,*

$$\widetilde{P} \times_S \mathrm{id}_A : (K^\vee)^\natural \times_{(S^{op})^\sharp} \widetilde{\mathcal{O}}(S)^\sharp \times_S A^\sharp \longrightarrow {}_\natural K \times_S A^\sharp$$

is a cocartesian equivalence in $s\mathbf{Set}^+_{/A}$.

Proof. Let (Z, E) denote the marked simplicial set $(K^\vee)^\natural \times_{(S^{op})^\sharp} \widetilde{\mathcal{O}}(S)^\sharp$. Viewing Z as $\widetilde{\mathcal{O}}(S) \times_{S^{op}\times S} (K^\vee \times S)$, we see that $Z \longrightarrow S$ is a cocartesian fibration with the cocartesian edges a subset of E. Moreover, every edge in E factors as a cocartesian edge followed by an edge in E in the fiber over S. By Proposition 13.4, it suffices to verify that for all $s \in S$, $\widetilde{P}_s$ is a cocartesian equivalence in $s\mathbf{Set}^+$. Since id_s is an initial object in $\widetilde{\mathcal{O}}(S) \times_S \{s\}$, the inclusion of the fiber $(K^\vee)^\sim_s \subset (Z_s, E_s)$ is a cocartesian equivalence in $s\mathbf{Set}^+$ by [10, Lemma 3.3.4.1]. We chose $\widetilde{P}$ so as to split the inclusion of K_s in Z, so this completes the proof. $\square$

Consider the commutative diagram

$$\begin{array}{ccccccccc}
\mathcal{O}(S)^\sharp \times_S {}_\natural K & & & \xrightarrow{\qquad\qquad\qquad\qquad \mathrm{ev}_1 \qquad\qquad\qquad\qquad} & & & & & S^\sharp \\
& \nwarrow^{\mathrm{id}_{\mathcal{O}(S)}\times_S \widetilde{P}} & & & & & & & \\
& & \mathcal{O}(S)^\sharp \times_{\mathrm{ev}_1,S,\mathrm{ev}_1} ((K^\vee)^\natural \times_{S^{op}} \widetilde{\mathcal{O}}(S)^\sharp) & \xrightarrow{\mathrm{pr}} & (K^\vee)^\natural \times_{S^{op}} \widetilde{\mathcal{O}}(S)^\sharp & \xrightarrow{\mathrm{id}\times\mathrm{ev}_1} & (K^\vee)^\natural \times S^\sharp & \xrightarrow{\mathrm{pr}_S} & S^\sharp \\
& & \downarrow{\scriptstyle\mathrm{pr}} & & \downarrow{\scriptstyle\mathrm{pr}} & & \downarrow{\scriptstyle q^\vee\times\mathrm{id}} & & \\
& & \mathcal{O}(S)^\sharp \times_{\mathrm{ev}_1,S,\mathrm{ev}_1} \widetilde{\mathcal{O}}(S)^\sharp & \xrightarrow{\pi'} & \widetilde{\mathcal{O}}(S)^\sharp & \xrightarrow{\mathrm{ev}} & (S^{op})^\sharp \times S^\sharp & & \\
& \searrow_{\mathrm{ev}_0} & \downarrow{\scriptstyle\pi} & & & & & & \\
& & S^\sharp. & & & & & &
\end{array}$$

Here, $\pi = \mathrm{ev}_0 \circ \mathrm{pr}_{\mathcal{O}(S)}$ and $\pi' = \mathrm{pr}_{\widetilde{\mathcal{O}}(S)}$. Since $K^\vee \longrightarrow S^{op}$ is a cartesian fibration, by Theorem 2.24 $(q^\vee \times \mathrm{id})_*$ is right Quillen. Therefore, given a S-category C, we obtain a $\widetilde{\mathcal{O}}(S)$-category

$$\{K, C\}_S := (\mathrm{ev}^* \circ (q^\vee \times \mathrm{id})_* \circ \mathrm{pr}_S^*)({}_\natural C).$$

Moreover, we saw in Example 2.26 that $\pi_* \pi'^*$ is right Quillen and computes right Kan extension along $\mathrm{ev}_1 : \widetilde{\mathcal{O}}(S) \longrightarrow S$. Finally, the map $\mathrm{id}_{\mathcal{O}(S)} \times_S \widetilde{P}$ induces a S-functor

$$\theta : \underline{\mathrm{Fun}}_S(K, C) \longrightarrow \pi_* \pi'^* \{K, C\}_S, \tag{6.3.1}$$

natural in K and C. By Proposition 6.3 applied to $A = S^{s/}$ for all $s \in S$, θ is an equivalence.

6.4. **Remark.** As a corollary, the global sections of $\{K, C\}_S$ are equivalent to $\mathrm{Fun}_S(K, C)$. If we knew that under the straightening functor St, $\{K, C\}_S$ was equivalent to the composite

$$\widetilde{\mathcal{O}}(S) \longrightarrow S^{op} \times S \xrightarrow{\mathrm{St}_S(K)^{op} \times \mathrm{St}_S(C)} \mathbf{Cat}_\infty^{op} \times \mathbf{Cat}_\infty \xrightarrow{\mathrm{Fun}} \mathbf{Cat}_\infty,$$

then this would yield another proof of the end formula for the ∞-category of natural transformations, as proven in [6, §6]. As we manage to always stay within the environment of cocartesian fibrations, this identification is not necessary for our purposes.

6.5. **Definition.** Given a S-functor $p : K \longrightarrow C$ and a choice of twisted pushforward $\widetilde{P}$ for K, define the cocartesian section $\omega_p : \widetilde{\mathcal{O}}(S) \longrightarrow \{K, C\}_S$ to be the adjoint to

$$p \circ \widetilde{P} : K^{\vee\natural} \times_{S^{op}} \widetilde{\mathcal{O}}(S)^\sharp \longrightarrow {}_\natural K \longrightarrow {}_\natural C.$$

For objects $[\alpha : s \to t]$ in $\widetilde{\mathcal{O}}(S)$, $\omega_p(\alpha) \in \mathrm{Fun}((K^\vee)_s, C_t)$ is the functor

$$p_t \circ \widetilde{P}_\alpha : (K^\vee)_s \longrightarrow K_t \longrightarrow C_t.$$

Define the *twisted slice* $\widetilde{\mathcal{O}}(S)$*-category* to be

$$C^{\widetilde{(p,S)}/} := \widetilde{\mathcal{O}}(S) \times_{\{K,C\}_S} \{K \star_S S, C\}_S.^{17}$

Note that the fiber of $C^{\widetilde{(p,S)}/}$ over an object $[\alpha : s \to t]$ is $C^{p_t \circ \widetilde{P}_\alpha /}$.

We now connect the constructions $C^{\widetilde{(p,S)}/}$ and $C^{(p,S)/}$. A check of the definitions reveals that $\theta \circ \sigma_p = \pi_* \pi'^*(\omega_p)$ for the canonical cocartesian section $\sigma_p : S \longrightarrow \underline{\mathrm{Fun}}_S(K, C)$. We thus have a morphism of spans

$$\begin{array}{ccccc}
S & \xrightarrow{\sigma_p} & \underline{\mathrm{Fun}}_S(K, C) & \longleftarrow & \underline{\mathrm{Fun}}_S(K \star_S S, C) \\
\downarrow{=} & & \downarrow{\simeq} & & \downarrow{\simeq} \\
S & \xrightarrow{\pi_* \pi'^*(\omega_p)} & \pi_* \pi'^* \{K, C\}_S & \longleftarrow & \pi_* \pi'^* \{K \star_S S, C\}_S
\end{array}$$

with all objects fibrant and the right horizontal maps fibrations by a standard argument. Taking pullbacks, we deduce:

---

[17] We omit the dependence on $\widetilde{P}$ from the notation.

6.6. **Theorem.** *We have an equivalence*

$$\pi_* \pi'^* (\widetilde{C^{(p,S)/}}) \xrightarrow{\simeq} C^{(p,S)/}.$$

In other words, the right Kan extension of $\widetilde{C^{(p,S)/}}$ *along the target functor* $\mathrm{ev}_1 : \widetilde{\mathcal{O}}(S) \longrightarrow S$ *is equivalent to* $C^{(p,S)/}$.

Proof. Our interpretation of this equivalence is by Example 2.26. □

Relative cofinality. Let us now apply Theorem 6.6. We have the S-analogue of the basic cofinality result [10, Proposition 4.1.1.8].

6.7. **Theorem.** *Let* $f : K \longrightarrow L$ *be a* S*-functor. The following conditions are equivalent:*

(1) *For every object* $s \in S$, $f_s : K_s \longrightarrow L_s$ *is final.*
(2) *For every* S*-functor* $p : L \longrightarrow C$*, the functor* $f^* : C^{(p,S)/} \longrightarrow C^{(pf,S)/}$ *is an equivalence.*
(3) *For every* S*-colimit diagram* $\overline{p} : L \star_S S \longrightarrow C$, $\overline{p} \circ f^{\rhd} : K \star_S S \longrightarrow C$ *is a* S*-colimit diagram.*

Proof. (1) ⇒ (2): Factoring f as the composition of a cofibration and a trivial fibration, we may suppose that f is a cofibration, in which case we may choose compatible twisted pushforward functors $\widetilde{P}_K$ and $\widetilde{P}_L$. Let $p : L \longrightarrow C$ be a S-functor. Precomposition by f yields a $\widetilde{\mathcal{O}}(S)$-functor $\widetilde{f^*}$: $\widetilde{C^{(p,S)/}} \longrightarrow \widetilde{C^{(pf,S)/}}$. Passing to the fiber over an object $\alpha : s \longrightarrow t$, the compatibility of $\widetilde{P}_K$ and $\widetilde{P}_L$ implies that the diagram

$$\begin{array}{ccccc} (K^\vee)_s & \xrightarrow{(\widetilde{P}_K)_\alpha} & K_t & & \\ \downarrow{\scriptstyle (f^\vee)_s} & & \downarrow{\scriptstyle f_t} & \searrow^{(pf)_t} & \\ (L^\vee)_s & \xrightarrow{(\widetilde{P}_L)_\alpha} & L_t & \xrightarrow{p_t} & C_t \end{array}$$

commutes and that

$$(\widetilde{f^*})_\alpha = (f^\vee)^*_s : C^{p_t \circ (\widetilde{P}_L)_\alpha /} \longrightarrow C^{(pf)_t \circ (\widetilde{P}_K)_\alpha /}.$$

By [10, Corollary 4.1.1.10], $(f^\vee)_s$ is final, so by [10, Proposition 4.1.1.8], $(f^\vee)^*_s$ is an equivalence. Consequently, $\widetilde{f^*}$ is an equivalence. Now by Theorem 6.6, f^* is an equivalence.

(2) ⇒ (3): Immediate from the definition.

(3) ⇒ (1): Let $s \in S$ be any object and $\overline{p_s} : L_s^{\rhd} \longrightarrow \mathbf{Spc}$ a colimit diagram. Let $\overline{p} : (L \star_S S)_{\underline{s}} \longrightarrow \mathbf{Spc}$ be a left Kan extension of $\overline{p_s}$ along the full and faithful inclusion $L_s^{\rhd} \subset (L \star_S S)_{\underline{s}}$. By transitivity of left Kan extensions, $\overline{p}$ is a left Kan extension of its restriction to $L_{\underline{s}}$. By Proposition 5.5, under the equivalence $\mathrm{Fun}(L, \mathbf{Spc}) \simeq \mathrm{Fun}_S(L, \underline{\mathbf{Spc}}_S)$, $\overline{p}$ is a $S^{s/}$-colimit diagram. By assumption, $\overline{p} \circ (f^{\rhd})_{\underline{s}}$ is a $S^{s/}$-colimit diagram. By Proposition 5.5 again, $\overline{p_s} \circ f_s$ is a colimit diagram, as desired. □

6.8. **Definition.** Let $f : K \longrightarrow L$ be a S-functor. We say that f is *S-final* if it satisfies the equivalent conditions of Theorem 6.7. We say that f is *S-initial* if f^{vop} is S-final.

6.9. **Example.** Let $F : C \rightleftarrows D : G$ be a S-adjunction (Definition 8.3). Then F is S-initial and G is S-final.

6.10. **Remark.** Let C, D be S-categories and $F : C \longrightarrow D$ an S-functor.

(1) Suppose F is fiberwise a weak homotopy equivalence. Then F is a weak homotopy equivalence by [10, Proposition 4.1.2.15], [10, Proposition 4.1.2.18], and [10, Proposition 3.1.5.7].
(2) Suppose F is S-final. Then F is final. Indeed, for any diagram $p : D \longrightarrow \mathbf{Spc}$, we have that
$$\operatorname*{colim}_{d \in D} p(d) \simeq \operatorname*{colim}_{s \in S} \operatorname*{colim}_{d \in D_s} p(d) \simeq \operatorname*{colim}_{s \in S} \operatorname*{colim}_{c \in C_s} pF(c) \simeq \operatorname*{colim}_{c \in C} pF(c).$$
(3) Suppose F is S-initial. Then F is initial. To show this, by (the dual of) [10, Theorem 4.1.3.1] it suffices to show that for every $d \in D$, $C \times_D D^{/d}$ is weakly contractible. Let s be the image of d in S. By Lemma 10.9, the inclusion $C_s \times_{D_s} (D_s)^{/d} \longrightarrow C \times_D D^{/d}$ is final, so in particular is a weak homotopy equivalence. Hence the desired conclusion follows by our assumption that F is S-initial and [10, Theorem 4.1.3.1] again.

We conclude by using the twisted slice $\widetilde{\mathcal{O}}(S)$-category to give a criterion for the presentability of the S-slice.

6.11. **Remark** (Presentability of the parametrized slice)**.** Suppose the functor $S \longrightarrow \mathbf{Cat}_\infty$ classifying the cocartesian fibration $C \longrightarrow S$ factors through $\mathbf{Pr}^R$, i.e. $C \longrightarrow S$ is a *right presentable fibration.* For any X a presentable ∞-category and diagram $f : A \longrightarrow X$, $X^{f/}$ is again presentable and the forgetful functor $X^{f/} \longrightarrow X$ creates limits and filtered colimits. Therefore, the twisted slice $\widetilde{\mathcal{O}}(S)$-category $C^{\widetilde{(p,S)}/}$ is a right presentable fibration. Since the forgetful functor $\mathbf{Pr}^R \longrightarrow \mathbf{Cat}_\infty$ creates limits, by Theorem 6.6 we deduce that $C^{(p,S)/}$ is a right presentable fibration. In particular, in every fiber there exists an initial object. However, these initial objects may fail to be preserved by the pushforward functors. In fact, even if we assume that $C \longrightarrow S$ is both left and right presentable, C may fail to be S-cocomplete.

7. Types of S-fibrations

In this section we introduce some additional classes of fibrations which are all defined relative to S.

7.1. **Definition.** Let $\phi : C \longrightarrow D$ be an S-functor. We say that ϕ is an *S-fibration* if it is a categorical fibration. We then say that ϕ is an *S-cocartesian fibration* if it is an S-fibration such that for every object $s \in S$, $\phi_s : C_s \longrightarrow D_s$ is a cocartesian fibration, and for every square in C

$$\begin{array}{ccc} x_s & \xrightarrow{h} & x_t \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle g} \\ y_s & \xrightarrow{k} & y_t \end{array}$$

with h and k ϕ-cocartesian edges over $\phi(h) = \phi(k) : s \longrightarrow t$, if f is a ϕ_s-cocartesian edge then g is a ϕ_t-cocartesian edge.

Dually, we say that ϕ is an *S-cartesian fibration* if it is an S-fibration such that for every object $s \in S$, $\phi_s : C_s \longrightarrow D_s$ is a cartesian fibration, and for every square in C labeled as above, but now with h and k ϕ-cartesian edges over $\phi(h) = \phi(k) : s \longrightarrow t$, if f is a ϕ_s-cartesian edge then g is a ϕ_t-cartesian edge.

Equivalently, $\phi : C \longrightarrow D$ is S-(co)cartesian if it is a categorical fibration, fiberwise a (co)cartesian fibration, and for every edge in S, the cocartesian pushforward along that edge preserves (co)cartesian edges in the fibers. We formulate our definition as above so as to avoid having to make any 'straightening' constructions such as choosing pushforward functors.

7.2. **Remark.** Declare a morphism of S-cocartesian fibrations $[C \xrightarrow{\phi} D] \longrightarrow [C' \xrightarrow{\phi'} D']$ to be a commutative square of S-functors

$$\begin{array}{ccc} C & \xrightarrow{F} & C' \\ \downarrow{\scriptstyle \phi} & & \downarrow{\scriptstyle \phi'} \\ D & \xrightarrow{G} & D' \end{array}$$

in which for all $s \in S$, F_s sends ϕ_s-cocartesian edges to ϕ'_s cocartesian edges. Let $\mathcal{O}^{\text{cocart.fib}}(\mathbf{Cat}^{cocart}_{\infty/S})$ be the ∞-category of S-cocartesian fibrations and morphisms thereof. Then one has the straightening equivalence

$$\mathcal{O}^{\text{cocart.fib}}(\mathbf{Cat}^{cocart}_{\infty/S}) \simeq \text{Fun}(S, \mathcal{O}^{\text{cocart.fib}}(\mathbf{Cat}_\infty)).$$

7.3. **Remark.** $\phi : C \longrightarrow D$ is a S-fibration if and only if $\phi : {}_\natural C \longrightarrow {}_\natural D$ is a marked fibration.

7.4. **Remark.** In view of [10, Proposition 2.4.2.11], [10, Lemma 2.4.2.7], and [10, Proposition 2.4.2.8], $\phi : C \longrightarrow D$ is an S-cocartesian fibration if and only if ϕ is a cocartesian fibration. However, there is no corresponding simplification of the definition of an S-cartesian fibration.

7.5. **Lemma.** *Let $\phi : C \longrightarrow D$ be a S-cartesian fibration and let $f : x \longrightarrow y$ be a ϕ_s-cartesian edge in C_s. Then f is a ϕ-cartesian edge.*

Proof. The property of being ϕ-cartesian may be checked after base-change to the 2-simplices of D. Consequently, we may suppose that $S = \Delta^1$ and $s = \{1\}$. We have to verify that for every object $w \in C$ we have a homotopy pullback square

$$\begin{array}{ccc} \mathrm{Map}_C(w,x) & \xrightarrow{f_*} & \mathrm{Map}_C(w,y) \\ \downarrow{\scriptstyle \phi_*} & & \downarrow{\scriptstyle \phi_*} \\ \mathrm{Map}_D(\phi w, \phi x) & \xrightarrow{\phi(f)_*} & \mathrm{Map}_D(\phi w, \phi y). \end{array}$$

If $w \in C_0$, for any choice of cocartesian edge $w \longrightarrow w'$ over $0 \longrightarrow 1$, the square is equivalent to

$$\begin{array}{ccc} \mathrm{Map}_{C_1}(w',x) & \xrightarrow{f_*} & \mathrm{Map}_{C_1}(w',y) \\ \downarrow{\scriptstyle \phi_*} & & \downarrow{\scriptstyle \phi_*} \\ \mathrm{Map}_{D_1}(\phi w', \phi x) & \xrightarrow{\phi(f)_*} & \mathrm{Map}_{D_1}(\phi w', \phi y). \end{array}$$

Hence we may suppose that $w \in C_1$, in which case the square is a homotopy pullback square since f is a ϕ_1-cartesian edge. □

We next discuss an important example of S-(co)cartesian fibrations. Recall (Notation 4.29) the fiberwise arrow S-category $\mathcal{O}_S(D)$. Fix $\phi : C \longrightarrow D$ a S-functor.

7.6. **Definition.** The *free S-cocartesian* and *free S-cartesian* fibrations on ϕ are the S-functors

$$\mathrm{Fr}^{cocart}(\phi) := \mathrm{ev}_1 \circ \mathrm{pr}_2 : C \times_D \mathcal{O}_S(D) \longrightarrow D,$$

$$\mathrm{Fr}^{cart}(\phi) := \mathrm{ev}_0 \circ \mathrm{pr}_1 : \mathcal{O}_S(D) \times_D C \longrightarrow D.$$

7.7. **Proposition.** *$Fr^{cocart}(\phi)$ is a S-cocartesian fibration. Dually, $Fr^{cart}(\phi)$ is a S-cartesian fibration.*

Proof. We prove the second assertion, the proof of the first being similar but easier. First note that $\mathcal{O}_S(D) \times_D C$ is a subcategory of $\mathcal{O}(D) \times_D C$ stable under equivalences. Therefore, since $\mathrm{ev}_0 : \mathcal{O}(D) \times_D C \longrightarrow D$ is a cartesian fibration, $\mathrm{Fr}^{cart}(\phi)$ is a categorical fibration. Moreover, for every object $s \in S$, $\mathrm{Fr}^{cart}(\phi)_s : \mathcal{O}(D_s) \times_{D_s} C_s$ is the free cartesian fibration on $\phi_s : C_s \longrightarrow D_s$. It remains to show that for every square

$$\begin{array}{ccc} (a \to \phi x, x) & \xrightarrow{h} & (b \to \phi y, y) \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle g} \\ (a' \to \phi x', x') & \xrightarrow{k} & (b' \to \phi y', y') \end{array}$$

in $\mathcal{O}_S(D) \times_D C$ with the horizontal edges cocartesian over S and the left vertical edge $\mathrm{Fr}^{cart}(\phi)_s$-cartesian, the right vertical edge is $\mathrm{Fr}^{cart}(\phi)_t$-cartesian. This amounts to verifying that $y \to y'$ is an equivalence in C_t. The above square yields a square

$$\begin{array}{ccc} x & \xrightarrow{h} & y \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle g} \\ x' & \xrightarrow{k} & y' \end{array}$$

in C with $x \to x'$ an equivalence and the horizontal edges cocartesian over S, from which the claim follows. □

We conclude this section with an observation about the interaction between S-joins and S-cocartesian fibrations which will be used in the sequel.

7.8. **Lemma.** *Let C, C', and D be S-categories and let $\phi, \phi' : C, C' \longrightarrow D$ be S-functors. If ϕ and ϕ' are S-(co)cartesian, then $\phi \star \phi' : C \star_D C' \longrightarrow D$ is S-(co)cartesian.*

Proof. This is an easy corollary of Proposition 4.7. □

7.9. **Definition.** We say that a S-functor $F : C \longrightarrow D \times_S E$ is a *S-bifibration* if for all objects $s \in S$, F_s is a bifibration. Observe it is then automatic that $\mathrm{pr}_D F$ is S-cartesian and $\mathrm{pr}_E F : C \longrightarrow E$ is S-cocartesian.

7.10. **Example.** The S-functor

$$\underline{\mathrm{Fun}}_S(K \star_S L, C) \longrightarrow \underline{\mathrm{Fun}}_S(K, C) \times_S \underline{\mathrm{Fun}}_S(L, C)$$

is a S-bifibration by Lemma 4.8. In particular, for a S-functor $p : K \longrightarrow C$, the S-functors $C^{(p,S)/} \longrightarrow C$ and $C^{/(p,S)} \longrightarrow C$ are S-cocartesian resp. S-cartesian.

8. Relative adjunctions

In [12, §7.3.2], Lurie introduces the notion of a *relative adjunction*.

8.1. **Definition** ([12, Definition 7.3.2.2])**.** Suppose given categorical fibrations $q : C \longrightarrow S$, $p : D \longrightarrow S$ and functors $F : C \longrightarrow D$, $G : D \longrightarrow C$ over S. Suppose there exists a natural transformation $u : \mathrm{id}_C \longrightarrow GF$ such that

1. u exhibits F as a left adjoint to G, and
2. $q(u)$ is the identity transformation from q to itself.

Then we say that the adjunction $F \dashv G$ is a *relative adjunction* with respect to S.

8.2. **Recollection.** By [12, Proposition 7.3.2.5], relative adjunctions are stable under base-change; in particular, they restrict to adjunctions over every fiber.

8.3. **Definition.** Let C and D be S-categories. We call a relative adjunction (with respect to S)

$$F\colon C \rightleftarrows D : G$$

an *S-adjunction* if F and G are S-functors.

We prove some basic results about S-adjunctions in this section. Let us first reformulate the definition of a relative adjunction in terms of a correspondence. Let $F : C \longrightarrow D$ be a S-functor. By the relative nerve construction, F defines a cocartesian fibration $M \longrightarrow \Delta^1$ by prescribing, for every $\Delta^n \cong \Delta^{n_0} \star \Delta^{n_1} \longrightarrow \Delta^1$, the set $\mathrm{Hom}_{\Delta^1}(\Delta^n, M)$ to be the collection of commutative squares

$$\begin{array}{ccc} \Delta^{n_0} & \longrightarrow & C \\ \downarrow & & \downarrow{\scriptstyle F} \\ \Delta^n & \longrightarrow & D \end{array}$$

for $n_1 \geq 0$, and setting $\mathrm{Hom}_{\Delta^1}(\Delta^n, M) = \mathrm{Hom}(\Delta^n, C)$ for $n_1 = -1$. Moreover, the structure maps for C and D to S define a functor $M \longrightarrow S$ by sending $\Delta^n \longrightarrow M$ to $\Delta^n \longrightarrow D \longrightarrow S$ if $n_1 \geq 0$, and $\Delta^n \longrightarrow C \longrightarrow S$ if $n_1 < 0$. Then M is a S-category, $M \longrightarrow S \times \Delta^1$ is a S-cocartesian fibration, and F admits a right S-adjoint if and only if $M \longrightarrow S \times \Delta^1$ is a S-cartesian fibration.

8.4. **Proposition.** *Let $F\colon C \rightleftarrows D : G$ be a S-adjunction and let I be a S-category. Then we have adjunctions*

$$F_*\colon \mathrm{Fun}_S(I, C) \rightleftarrows \mathrm{Fun}_S(I, D) : G_*$$
$$G^*\colon \mathrm{Fun}_S(C, I) \rightleftarrows \mathrm{Fun}_S(D, I) : F^*$$

Proof. Let $M \longrightarrow S \times \Delta^1$ be the S-functor obtained from F. We first produce the adjunction $F_* \dashv G_*$. Invoking Theorem 2.24 on the span

$$(\Delta^1) \xleftarrow{\pi} {}_\natural I \times (\Delta^1)^\sharp \xrightarrow{\pi'} S^\sharp \times (\Delta^1)^\sharp$$

we deduce that $\pi_* \pi'^* : s\mathbf{Set}^+_{/(S^\sharp \times (\Delta^1)^\sharp)} \longrightarrow s\mathbf{Set}^+_{/(\Delta^1)^\sharp}$ is right Quillen. Let $N = \pi_* \pi'^*(M)$. Then $N \longrightarrow \Delta^1$ is a cocartesian fibration classified by the functor

$$F_* : \mathrm{Fun}_S(I, C) \longrightarrow \mathrm{Fun}_S(I, D).$$

Now invoking Theorem 2.24 on the span

$$((\Delta^1)^\sharp)^{op} \xleftarrow{\rho} (I^\sim \times (\Delta^1)^\sharp)^{op} \xrightarrow{\rho'} (S^\sim \times (\Delta^1)^\sharp)^{op}$$

we deduce that with respect to the cartesian model structures $\rho_*\rho'^* : s\mathbf{Set}^+_{/(S^\sim\times(\Delta^1)^\sharp)} \longrightarrow s\mathbf{Set}^+_{/(\Delta^1)^\sharp}$ is right Quillen. Let $N' = \rho_*\rho'^*M$. Since G is right S-adjoint to F, $N' \longrightarrow \Delta^1$ is a cartesian fibration classified by the functor

$$G_* : \mathrm{Fun}_{/S}(I, D) \longrightarrow \mathrm{Fun}_{/S}(I, C)$$

where we view I, C, D as categorical fibrations over S. N is a subcategory of N', and the cartesian edges e in N' with $d_0(e) \in N$ are in N. Hence $N \longrightarrow \Delta^1$ is also a cartesian fibration classified by the functor

$$G_* : \mathrm{Fun}_S(I, D) \longrightarrow \mathrm{Fun}_S(I, C).$$

We now produce the adjunction $G^* \dashv F^*$ by similar methods. Let $\mathcal{E}_0$ be the collection of edges $e : x \longrightarrow y$ in M such that e admits a factorization as a cocartesian edge over S followed by a cartesian edge in the fiber. Note that since $M \longrightarrow S \times \Delta^1$ is a S-cartesian fibration, $\mathcal{E}_0$ is closed under composition of edges. Invoking Theorem 2.24 on the span

$$(\Delta^1)^\sharp \xleftarrow{\mu} (M, \mathcal{E}_0) \xrightarrow{\mu'} S^\sharp \times (\Delta^1)^\sharp$$

we deduce that $\mu_*\mu'^* : s\mathbf{Set}^+_{/(S^\sharp\times(\Delta^1)^\sharp)} \longrightarrow s\mathbf{Set}^+_{/(\Delta^1)^\sharp}$ is right Quillen. Let $P = \mu_*\mu'^*({}_\natural I \times (\Delta^1)^\sharp)$. Then $P \longrightarrow \Delta^1$ is a cocartesian fibration classified by the functor

$$G^* : \mathrm{Fun}_S(C, I) \longrightarrow \mathrm{Fun}_S(D, I).$$

Let $\mathcal{E}_1$ be the collection of edges $e : x \longrightarrow y$ in M such that e is a cocartesian edge over an equivalence in S. Now invoking Theorem 2.24 on the span

$$((\Delta^1)^\sharp)^{op} \xleftarrow{\nu} (M, \mathcal{E}_1)^{op} \xrightarrow{\nu'} (S^\sim \times (\Delta^1)^\sharp)^{op}$$

we deduce that with respect to the cartesian model structures $\nu_*\nu'^* : s\mathbf{Set}^+_{/(S^\sim\times(\Delta^1)^\sharp)} \longrightarrow s\mathbf{Set}^+_{/(\Delta^1)^\sharp}$ is right Quillen. Let $P' = \nu_*\nu'^*(I^\sim \times (\Delta^1)^\sharp)$. $P' \longrightarrow \Delta^1$ is a cartesian fibration with P as a subcategory. One may check that $P \longrightarrow \Delta^1$ inherits the property of being a cartesian fibration, which is classified by the functor $F^* : \mathrm{Fun}_S(D, I) \longrightarrow \mathrm{Fun}_S(C, I)$. □

8.5. **Corollary.** *Let $F : C \rightleftarrows D : G$ be a S-adjunction and let I be a S-category. Then we have S-adjunctions*

$$F_* : \underline{\mathrm{Fun}}_S(I, C) \rightleftarrows \underline{\mathrm{Fun}}_S(I, D) : G_*$$
$$G^* : \underline{\mathrm{Fun}}_S(C, I) \rightleftarrows \underline{\mathrm{Fun}}_S(D, I) : F^*$$

Proof. By Proposition 8.4, for every $s \in S$

$$F_* : \mathrm{Fun}_{S^{s/}}(I \times_S S^{s/}, C \times_S S^{s/}) \rightleftarrows \mathrm{Fun}_{S^{s/}}(I \times_S S^{s/}, D \times_S S^{s/}) : G_*$$

is an adjunction, and similarly for the contravariant case. □

To state the next corollary, it is convenient to introduce a definition.

8.6. **Definition.** Suppose $\pi : C \longrightarrow D$ a S-fibration. Define the ∞-category $\mathbf{Sect}_{D/S}(\pi)$ of S-sections of π to be the pullback

$$\begin{array}{ccc} \mathbf{Sect}_{D/S}(\pi) & \longrightarrow & \mathrm{Fun}_S(D, C) \\ \downarrow & & \downarrow \pi_* \\ \Delta^0 & \xrightarrow{\mathrm{id}_D} & \mathrm{Fun}_S(D, D). \end{array}$$

Define the S-category $\underline{\mathbf{Sect}}_{D/S}(\pi)$ to be the pullback

$$\begin{array}{ccc} \underline{\mathbf{Sect}}_{D/S}(\pi) & \longrightarrow & \underline{\mathrm{Fun}}_S(D, C) \\ \downarrow & & \downarrow \pi_* \\ S & \xrightarrow{\sigma_{\mathrm{id}_D}} & \underline{\mathrm{Fun}}_S(D, D). \end{array}$$

We will often denote $\mathbf{Sect}_{D/S}(\pi)$ by $\mathbf{Sect}_{D/S}(C)$, the S-functor π being left implicit.

Note that for any object $s \in S$, the fiber $\underline{\mathbf{Sect}}_{D/S}(\pi)_s$ is isomorphic to $\mathbf{Sect}_{D_{\underline{s}}/\underline{s}}(\pi_{\underline{s}})$.

8.7. **Corollary.** *Let $p : C \longrightarrow E$ and $q : D \longrightarrow E$ be S-fibrations. Let $F\colon C \rightleftarrows D : G$ be an adjunction relative to E where F and G are S-functors. Then for any S-category I,*

$$F_*\colon \mathrm{Fun}_S(I,C) \rightleftarrows \mathrm{Fun}_S(I,D) : G_*$$

is an adjunction relative to $\mathrm{Fun}_S(I,E)$. In particular, taking $I = E$ and the fiber over the identity, we deduce that

$$F_*\colon \mathbf{Sect}_{E/S}(p) \rightleftarrows \mathbf{Sect}_{E/S}(q) : G_*$$

is an adjunction, and also that

$$F_*\colon \underline{\mathbf{Sect}}_{E/S}(p) \rightleftarrows \underline{\mathbf{Sect}}_{E/S}(q) : G_*$$

is a S-adjunction.

Proof. The proof of Proposition 8.4 shows that the unit for the adjunction $F_* \dashv G_*$ is sent by p_* to a natural transformation through equivalences. □

8.8. **Lemma.** *Let $F\colon C \rightleftarrows D : G$ be a S-adjunction. For every S-functor $p : K \longrightarrow D$, we have a homotopy pullback square in $s\mathbf{Set}^+_{/S}$*

$$\begin{array}{ccc} C^{/(Gp,S)} & \longrightarrow & D^{/(p,S)} \\ \downarrow{\scriptstyle \mathrm{ev}_0^C} & & \downarrow{\scriptstyle \mathrm{ev}_0^D} \\ C & \xrightarrow{F} & D \end{array}$$

where the upper horizontal map is defined to be the composite $C^{/(Gp,S)} \xrightarrow{F} C^{/(FGp,S)} \xrightarrow{\epsilon(p)_!} D^{/(p,S)}$. Dually, for every S-functor $p : K \longrightarrow D$, we have a homotopy pullback square in $s\mathbf{Set}^+_{/S}$

$$\begin{array}{ccc} D^{(Fp,S))/} & \longrightarrow & C^{(p,S)/} \\ \downarrow{\scriptstyle \mathrm{ev}_1^D} & & \downarrow{\scriptstyle \mathrm{ev}_1^C} \\ D & \xrightarrow{G} & C. \end{array}$$

where the upper horizontal map is defined to be the composite $D^{(Fp,S))/} \xrightarrow{G} C^{(GFp,S)/} \xrightarrow{\eta(p)^*} C^{(p,S)/}$.

Proof. We prove the first assertion; the second then follows by taking vertical opposites. We first explain how to define the map $\epsilon(p)_!$. Choose a counit transformation $\epsilon : D \times \Delta^1 \longrightarrow D$ for $F \dashv G$ such that $\pi_D \circ \epsilon$ is the identity natural transformation from π_D to itself. Then $\epsilon \circ (p \times \mathrm{id})$ is adjoint to a S-functor $\epsilon(p) : S \times \Delta^1 \longrightarrow \underline{\mathrm{Fun}}_S(K,D)$ with $\epsilon(p)_0 = \sigma_{FGp}$ and $\epsilon(p)_0 = \sigma_p$. Because $\underline{\mathrm{Fun}}_S(S \star_S K, D) \longrightarrow D \times_S \underline{\mathrm{Fun}}_S(K,D)$ is an S-bifibration, from $\epsilon(p)$ we obtain a pushforward S-functor $\epsilon(p)_! : D^{/(FGp,S)} \longrightarrow D^{/(p,S)}$ compatible with the source maps to D.

We need to check that for every object $s \in S$, passage to the fiber over s yields a homotopy pullback square of ∞-categories. Because $(D^{/(p,S)})_s \cong (D_{\underline{s}}^{/(p_{\underline{s}},\underline{s})})_s$, we may replace S by $S^{s/}$ and thereby suppose that s is an initial object in S.

Let $r : \{s\} \star S \longrightarrow S$ be a left Kan extension of the identity $S \longrightarrow S$. By the formula for a left Kan extension, $r(s)$ is an initial object in S, which without loss of generality we may suppose to be s. Using $r \circ (\mathrm{id} \star \pi_K)$ as the structure map for $\{s\} \star K$ over S, define $\phi' : \{s\} \star {}_\natural K \longrightarrow \{s\} \star_S {}_\natural K$ as adjoint to the identity over $S \times \partial\Delta^1$. It is easy to show that ϕ' is a trivial cofibration in $s\mathbf{Set}^+_{/S}$. Moreover, since the inclusion $\{s\} \longrightarrow S^\sharp$ is a trivial cofibration, $\{s\} \star_S {}_\natural K \longrightarrow S^\sharp \star_S {}_\natural K$ is a trivial cofibration in $s\mathbf{Set}^+_{/S}$ by Theorem 4.16. Let ϕ be the composition of these two maps. Then because $\mathrm{Fun}_S(-,-)$ is a right Quillen bifunctor, $\phi^* : \mathrm{Fun}_S(S^\sharp \star_S {}_\natural K, {}_\natural D) \longrightarrow \mathrm{Fun}_S(\{s\} \star {}_\natural K, {}_\natural D)$ is a trivial Kan fibration.

We further claim that the inclusion $j : \mathrm{Fun}_S(\{s\} \star {}_\natural K, {}_\natural D) \longrightarrow D_s \times_D \mathrm{Fun}(\{s\} \star K, D) \times_{\mathrm{Fun}(K,D)} \mathrm{Fun}_S({}_\natural K, {}_\natural D)$ is an equivalence. Indeed, we have the pullback square

$$\begin{array}{ccc} \mathrm{Fun}_S(\{s\} \star {}_\natural K, {}_\natural D) & \longrightarrow & D_s \times_D \mathrm{Fun}(\{s\} \star K, D) \times_{\mathrm{Fun}(K,D)} \mathrm{Fun}_S({}_\natural K, {}_\natural D) \\ \downarrow & & \downarrow \\ \Delta^0 & \xrightarrow{r \circ (\mathrm{id} \star \pi_K)} & \{s\} \times_S \mathrm{Fun}(\{s\} \star K, S) \times_{\mathrm{Fun}(K,S)} \{\pi_K\} \end{array}$$

and the term in the lower right is contractible since it is equivalent to the full subcategory $\mathrm{Fun}'(\{s\}\star K, S) \subset \mathrm{Fun}(\{s\}\star K, S)$ of functors which are left Kan extensions of π_K.

Now taking the pullback of the composition $j \circ \phi^*$ over $\{p\}$, we obtain an equivalence

$$(D^{/(p,S)})_s \longrightarrow D_s \times_D D^{/p}.$$

Similarly, we have an equivalence

$$(C^{/(Gp,S)})_s \longrightarrow C_s \times_C C^{/Gp}.$$

Since $F \dashv G$ is in particular an adjunction, by [10, Lemma 5.2.5.5] $C^{/Gp} \longrightarrow C \times_D D^{/p}$ is an equivalence. Taking the fiber over s, we deduce the claim. □

8.9. **Corollary.** *Let $F: C \rightleftarrows D: G$ be a S-adjunction. Then F preserves S-colimits and G preserves S-limits.*

Proof. Let $\overline{p} : K \star_S S \longrightarrow C$ be a S-colimit diagram. To show that $F\overline{p}$ is a S-colimit diagram, it suffices to prove that the restriction map $D^{(F\overline{p},S)/} \longrightarrow D^{(Fp,S)/}$ is an equivalence. We have the commutative square

$$\begin{array}{ccc} D^{(F\overline{p},S)/} & \longrightarrow & C^{(\overline{p},S)/} \times_C D \\ \downarrow & & \downarrow \\ D^{(Fp,S)/} & \longrightarrow & C^{(p,S)/} \times_C D \end{array}$$

(here we suppress some details about the naturality of $\epsilon(-)_!$). The righthand vertical map is an equivalence by assumption, and the horizontal maps are equivalences by Lemma 8.8. Thus the lefthand vertical map is an equivalence. □

Free S-(co)cartesian fibrations revisited. With the theory of S-adjunctions, we can now establish a key property of the free S-(co)cartesian fibration (Definition 7.6). Let $\phi : C \longrightarrow D$ be an S-functor and define S-functors

$$\iota_0 : C \longrightarrow C \times_D \mathcal{O}_S(D), \quad \iota_1 : C \longrightarrow \mathcal{O}_S(D) \times_D C$$

via the commutative square

$$\begin{array}{ccc} C & \longrightarrow & \mathcal{O}_S(D) \\ \downarrow{=} & & \downarrow{\mathrm{ev}_i} \\ C & \xrightarrow{\phi} & D \end{array}$$

where the upper horizontal map is the composite $C \xrightarrow{\iota} \mathcal{O}_S(C) \longrightarrow \mathcal{O}_S(D)$.

8.10. **Proposition.** *ι_0 is left S-adjoint to pr_C. Dually, ι_1 is right S-adjoint to pr_C.*

Proof. We prove the first assertion, the proof of the second being similar. To prove that we have a relative S-adjunction $\iota_0 \dashv \mathrm{pr}_C$, we must prove that for each $s \in S$ we have an adjunction $(\iota_0)_s \dashv (\mathrm{pr}_C)_s$. So suppose that $S = \Delta^0$. Since $\mathrm{pr}_C \circ \iota_0 = \mathrm{id}$, it suffices by [10, Proposition 5.2.2.8] to check that the identity is a unit transformation: that is, for every $x \in C$ and $(y, \phi y \to a) \in C \times_D \mathcal{O}(D)$,

$$\mathrm{pr}_C : \mathrm{Map}_{C\times_D \mathcal{O}(D)}((x, \mathrm{id}_{\phi x}), (y, \phi y \to a)) \longrightarrow \mathrm{Map}_C(x, y)$$

is an equivalence. Under the fiber product decomposition

$$\mathrm{Map}_{C\times_D \mathcal{O}(D)}((x, \mathrm{id}_{\phi x}), (y, \phi y \to a)) \simeq \mathrm{Map}_C(x, y) \times_{\mathrm{Map}_D(\phi x, \phi y)} \mathrm{Map}_{\mathcal{O}(D)}((\mathrm{id}_{\phi x}), (\phi y \to b))$$

the map pr_C is projection onto the first factor. The adjunction $\iota: D \rightleftarrows \mathcal{O}(D) : \mathrm{ev}_0$ obtained by exponentiating the adjunction $i_0: \{0\} \rightleftarrows \Delta^1 : p$ implies that

$$\mathrm{Map}_{\mathcal{O}(D)}((\mathrm{id}_{\phi x}), (\phi y \to b)) \longrightarrow \mathrm{Map}_D(\phi x, \phi y)$$

is an equivalence, so the claim follows. □

8.11. **Remark** (Universal property of the free S-cocartesian fibration)**.** Let $\phi : C \longrightarrow D$ be an S-functor and $\psi : E \longrightarrow D$ be an S-cocartesian fibration. Then we would like to show that the restriction functor

$$\mathrm{Fun}^{cocart}_{/D}(C \times_D \mathcal{O}_S(D), E) \longrightarrow \mathrm{Fun}_{/D,S}(C, E) = S \times_{\sigma_\phi, \mathrm{Fun}_S(C,D), \psi_*} \mathrm{Fun}_S(C, E)$$

is an equivalence of ∞-categories.[18] We prove this as [18, Example 3.8] as an application of the theory of parametrized factorization systems.

9. Parametrized colimits

In this section, we first introduce a parametrized generalization of Lurie's pairing construction [10, Corollary 3.2.2.13]. We then employ it to study *D-parametrized S-(co)limits.* This material recovers and extends [10, §4.2.2] (in view of Lemma 4.5). It is a precursor to our study of Kan extensions.

An S-pairing construction.

9.1. **Construction.** Let $p : C \longrightarrow S$, $q : D \longrightarrow S$ be S-categories and let $\phi : C \longrightarrow D$ be a S-functor. Let $\pi, \pi' : \mathcal{O}^{cocart}(D) \times_D C \longrightarrow D$ be given by $\pi = \mathrm{ev}_0 \circ \mathrm{pr}_1$, $\pi' = \mathrm{ev}_1 \circ \mathrm{pr}_1$. Let $\mathcal{E}$ denote the collection of edges e in $\mathcal{O}^{cocart}(D) \times_D C$ such that $\pi(e)$ is q-cocartesian and $\mathrm{pr}_2(e)$ is p-cocartesian (so $\pi'(e)$ is q-cocartesian). Then the span

$$\natural D \xleftarrow{\pi} (\mathcal{O}^{cocart}(D) \times_D C, \mathcal{E}) \xrightarrow{\pi'} \natural D$$

defines a functor

$$\pi_* \pi'^* : s\mathbf{Set}^+_{/\natural D} \longrightarrow s\mathbf{Set}^+_{/\natural D}.$$

For a S-category E and a S-functor $\psi : E \longrightarrow D$, define

$$(\widetilde{\mathrm{Fun}}_{D/S}(C, E) \longrightarrow \natural D) := \pi_* \pi'^*(\natural E \xrightarrow{\psi} \natural D).$$

9.2. **Lemma.** *Let $q : D \longrightarrow S$ be a S-category.*

(1) $\mathrm{ev}_0 : \mathcal{O}^{cocart}(D) \longrightarrow D$ is a cartesian fibration, and an edge e in $\mathcal{O}^{cocart}(D)$ is ev_0-cartesian if and only $(\mathrm{ev}_{S,1} \circ q)(e)$ is an equivalence in S. In particular, if $\mathrm{ev}_0(e)$ is q-cocartesian, then e is ev_0-cartesian if and only if $\mathrm{ev}_1(e)$ is an equivalence in D.

(2) If $f : x \longrightarrow y$ is an edge in D such that $q(f)$ is an equivalence, then there exists a ev_0-cocartesian edge e over f. Moreover, an edge e over f is ev_0-cocartesian if and only if it is ev_0-cartesian.

Proof. $\mathrm{ev}_0 : \mathcal{O}^{cocart}(D) \longrightarrow D$ factors as

$$\mathcal{O}^{cocart}(D) \longrightarrow D \times_S \mathcal{O}(S) \longrightarrow D$$

where the first functor is a trivial fibration and the second is a cartesian fibration, as the pullback of $\mathrm{ev}_{S,0} : \mathcal{O}(S) \longrightarrow S$. Thus ev_0 is a cartesian fibration with cartesian edges as indicated. Moreover, since $\mathrm{ev}_{S,0} : \mathcal{O}(S) \longrightarrow S$ is a categorical fibration, the second claim follows from [12, Proposition B.2.9]. $\square$

We have designed our construction so that for any object $x \in D$ and cocartesian section $S^{qx/} \longrightarrow D$, the fiber of $\widetilde{\mathrm{Fun}}_{D/S}(C, E) \longrightarrow D$ over x is equivalent to $\mathrm{Fun}_{S^{qx/}}(C \times_D S^{qx/}, E \times_D S^{qx/})$. For this reason, we think of $\widetilde{\mathrm{Fun}}_{D/S}(-,-)$ as the parametrized generalization of the pairing construction $\widetilde{\mathrm{Fun}}_D(-,-)$, to which it reduces when $S = \Delta^0$.

9.3. **Theorem.** *Notation as in Construction 9.1, $\widetilde{\mathrm{Fun}}_{D/S}(C, E)$ enjoys the following functoriality:*

(1) If ϕ is either a S-cartesian fibration or a S-cocartesian fibration and ψ is a categorical fibration, then $\widetilde{\mathrm{Fun}}_{D/S}(C, E) \longrightarrow S$ is a S-category with cocartesian edges marked as indicated in Construction 9.1, and $\widetilde{\mathrm{Fun}}_{D/S}(C, E) \longrightarrow D$ is a categorical fibration.

(2) If ϕ is a S-cartesian fibration and ψ is a S-cocartesian fibration, then $\widetilde{\mathrm{Fun}}_{D/S}(C, E) \longrightarrow D$ is a S-cocartesian fibration.

[18] We use Remark 7.4 to simplify the appearance of the lefthand side, which would otherwise be denoted as $\mathrm{Fun}^{cocart}_{/D,S}(C \times_D \mathcal{O}_S(D), E)$.

(3) If ϕ is a S-cocartesian fibration and ψ is a S-cartesian fibration, then $\widetilde{\mathrm{Fun}}_{D/S}(C,E) \longrightarrow D$ is a S-cartesian fibration.

Proof. (1) It suffices to check that Theorem 2.24 applies to the span

$$\natural D \xleftarrow{\pi} (\mathcal{O}^{cocart}(D) \times_D C, \mathcal{E}) \xrightarrow{\pi'} \natural D.$$

In the remainder of this proof we will verify that $\mathcal{O}^{cocart}(D) \times_D C \longrightarrow D$ is a flat categorical fibration. For condition (4) we appeal to Lemma 9.2. The rest of the conditions are easy verifications.

(2) By Lemma 9.2 and 7.5, $\pi : \mathcal{O}^{cocart}(D) \times_D C \longrightarrow D$ is a cartesian fibration (hence flat) with an edge e π-cartesian if and only if $\mathrm{pr}_1(e)$ is ev_0-cartesian and $\mathrm{pr}_2(e)$ is ϕ-cartesian. Let $\mathcal{E}'$ be the collection of edges e in $\mathcal{O}^{cocart}(D) \times_{\mathrm{ev}_1, D} C$ such that for any π-cartesian lift e' of $\pi(e)$, the induced edge $d_1(e) \longrightarrow d_1(e')$ is in $\mathcal{E}$. Note that since ϕ is S-cartesian (and not just fiberwise cartesian), $\mathcal{E}'$ is closed under composition. Invoking Theorem 2.24 on the span

$$D^\sharp \xleftarrow{\pi} (\mathcal{O}^{cocart}(D) \times_D C, \mathcal{E}') \xrightarrow{\pi'} D^\sharp$$

we deduce that

$$\pi_* \pi'^* : s\mathbf{Set}^+_{/D} \longrightarrow s\mathbf{Set}^+_{/D}$$

is right Quillen. Note that there is no conflict of notation with the functor $\pi_* \pi'^*$ defined before on $s\mathbf{Set}^+_{/\natural D}$ since $\mathcal{E} \subset \mathcal{E}'$ and the two restrict to the same collections of marked edges in the fibers of π. Since S-cocartesian fibrations are cocartesian fibrations over D (Remark 7.4), we conclude.

(3) First note that π factors as a cocartesian fibration followed by a cartesian fibration, so is flat. Let $\mathcal{F}$ be the collection of edges f in D such that $q(f)$ is an equivalence. By Lemma 9.2, we have that $\pi : \mathcal{O}^{cocart}(D) \times_{\mathrm{ev}_1, D} C \longrightarrow D$ admits cocartesian lifts of edges in $\mathcal{F}$. Let $\mathcal{E}''$ be the collection of those π-cocartesian edges. Invoking Theorem 2.24 on the span

$$(D, \mathcal{F})^{op} \xleftarrow{\rho} (\mathcal{O}^{cocart}(D) \times_D C, \mathcal{E}'')^{op} \xrightarrow{\rho'} (D, \mathcal{F})^{op},$$

where $\rho = \pi^{op}$ and $\rho' = \pi'^{op}$, we deduce that with respect to the cartesian model structures

$$\rho_* \rho'^* : s\mathbf{Set}^+_{/(D,\mathcal{F})} \longrightarrow s\mathbf{Set}^+_{/(D,\mathcal{F})}$$

is right Quillen. We have that $\widetilde{\mathrm{Fun}}_{D/S}(C,E)$ is a full subcategory of $\rho_* \rho'^*(\psi)$. Moreover, the compatibility condition in the definition of a S-cartesian fibration ensures that $\widetilde{\mathrm{Fun}}_{D/S}(C,E) \longrightarrow D$ inherits the property of being fibrant in $s\mathbf{Set}^+_{/(D,\mathcal{F})}$. Another routine verification shows that $\widetilde{\mathrm{Fun}}_{D/S}(C,E) \longrightarrow D$ is indeed S-cartesian.

□

9.4. **Lemma.** *Let $C \longrightarrow C'$ be a monomorphism between S-cartesian or S-cocartesian fibrations over D and let $E \longrightarrow D$ be a S-fibration. Then the induced functor*

$$\widetilde{\mathrm{Fun}}_{D/S}(C',E) \longrightarrow \widetilde{\mathrm{Fun}}_{D/S}(C,E)$$

is a categorical fibration.

Proof. Given a trivial cofibration $A \longrightarrow B$ in $s\mathbf{Set}_{\mathrm{Joyal}}$, we need to solve the lifting problem

$$\begin{array}{ccc} A & \longrightarrow & \widetilde{\mathrm{Fun}}_{D/S}(C',E) \\ \downarrow & \nearrow & \downarrow \\ B & \longrightarrow & \widetilde{\mathrm{Fun}}_{D/S}(C,E). \end{array}$$

This diagram transposes to

$$\begin{array}{ccc} A \times_D \mathcal{O}^{cocart}(D) \times_D C' \bigcup_{A \times_D \mathcal{O}^{cocart}(D) \times_D C} B \times_D \mathcal{O}^{cocart}(D) \times_D C & \longrightarrow & E \\ \downarrow & \nearrow & \downarrow \\ B \times_D \mathcal{O}^{cocart}(D) \times_D C' & \longrightarrow & D. \end{array}$$

By the proof of Theorem 9.3, $\mathcal{O}^{cocart}(D) \times_D C \longrightarrow D$ is a flat categorical fibration. Therefore, by [12, Proposition B.4.5] the left vertical arrow is a trivial cofibration in $s\mathbf{Set}_{\mathrm{Joyal}}$. □

For later use, we analyze some degenerate instances of the S-pairing construction.

9.5. **Lemma.** *There is a natural equivalence $\widetilde{\mathrm{Fun}}_{D/S}(D, E) \xrightarrow{\simeq} E$ of S-categories over D.*

Proof. The map is induced by the identity section $\iota_D : D \longrightarrow \mathcal{O}^{cocart}(D)$ fitting into a morphism of spans

$$\begin{array}{ccccc} & & {}_\natural D & & \\ & \swarrow^{=} & \downarrow{\scriptstyle \iota_D} & \searrow^{=} & \\ {}_\natural D & \longleftarrow & (\mathcal{O}^{cocart}(D), \mathcal{E}) & \longrightarrow & {}_\natural D. \end{array}$$

By Lemma 3.3(1'), ι_D is a cocartesian equivalence in $s\mathbf{Set}^+_{/S}$ via the target map. Since the cocartesian model structure on $s\mathbf{Set}^+_{/{}_\natural D}$ is created by the forgetful functor to $s\mathbf{Set}^+_{/S}$, the assertion follows. □

9.6. **Lemma.** *Let $C' \longrightarrow D'$ be a cartesian fibration of ∞-categories and let E' be a S-category. For all $s \in S$, there is a natural equivalence*

$$\widetilde{\mathrm{Fun}}_{D' \times S/S}(C' \times S, D' \times E')_s \xrightarrow{\simeq} \widetilde{\mathrm{Fun}}_{D'}(C', D' \times E'_s)$$

of cartesian fibrations over D'.

Proof. The lefthand side is defined using the span

$$(D')^\sharp \times \{s\} \longleftarrow ((D')^\sharp \times \{s\}) \times_{D' \times S} (\mathcal{O}^{cocart}(D' \times S) \times_{D'} C', \mathcal{E}') \longrightarrow S^\sharp$$

with $\mathcal{E}'$ as in the proof of Theorem 9.3. Cocartesian edges (over S) in $D' \times S$ are precisely those edges which become equivalences when projected to D', so $\mathcal{O}^{cocart}(D' \times S) \cong \mathrm{Fun}((\Delta^1)^\sharp, (D')^\sim) \times \mathcal{O}(S)$, and the identity section $\iota_{D'} : D' \longrightarrow \mathrm{Fun}((\Delta^1)^\sharp, (D')^\sim)$ is a categorical equivalence. Therefore, the map

$$(D' \times S^{s/})^\sharp \longrightarrow ((D')^\sharp \times \{s\}) \times_{D' \times S} (\mathcal{O}^{cocart}(D' \times S), \mathcal{E})$$

induced by $\iota_{D'}$ is a cocartesian equivalence in $s\mathbf{Set}^+_{/S}$. Since $C' \times S \longrightarrow D' \times S$ is a cartesian fibration, it follows that

$$(C')^\natural \times (S^{s/})^\sharp \longrightarrow ((D')^\sharp \times \{s\}) \times_{D' \times S} (\mathcal{O}^{cocart}(D' \times S) \times_{D'} C', \mathcal{E}')$$

is also a cocartesian equivalence in $s\mathbf{Set}^+_{/S}$. Finally, using the inclusion $C' \times \{s\} \longrightarrow C' \times S^{s/}$, we obtain a morphism from the span

$$(D')^\sharp \longleftarrow (C')^\natural \longrightarrow \{s\} \subset S^\sharp$$

through a cocartesian equivalence in $s\mathbf{Set}^+_{/S}$. This yields the equivalence of the lemma. □

Directly from the definition, we have that for an object $x \in D$, the fiber $\widetilde{\mathrm{Fun}}_{D/S}(C, E)_x$ is isomorphic to $\mathrm{Fun}_{\underline{x}}(C_{\underline{x}}, E_{\underline{x}})$. We now proceed to identify the S-fiber $\widetilde{\mathrm{Fun}}_{D/S}(C, E)_{\underline{x}}$.

9.7. **Proposition.** *There is a $\underline{x}$-functor*

$$\epsilon^* : \widetilde{\mathrm{Fun}}_{D/S}(C, E)_{\underline{x}} \longrightarrow \underline{\mathrm{Fun}}_{\underline{x}}(C_{\underline{x}}, E_{\underline{x}})$$

which is a cocartesian equivalence in $s\mathbf{Set}^+_{/\underline{x}}$.

Proof. We first define the $\underline{x}$-functor ϵ^*. The data of maps of marked simplicial sets

$$A \longrightarrow {}_\natural\widetilde{\mathrm{Fun}}_{D/S}(C, E)_{\underline{x}}$$
$$A \longrightarrow {}_\natural\underline{\mathrm{Fun}}_{\underline{x}}(C_{\underline{x}}, (E \times_S D)_{\underline{x}})$$

over $\underline{x}$ is identical to the data of maps

$$A \times_{\underline{x}} \underline{x}^\sharp \times_D (\mathcal{O}^{cocart}(D), \mathcal{E}) \times_D {}_\natural C \longrightarrow {}_\natural E$$
$$A \times_{\underline{x}} \mathcal{O}(\underline{x})^\sharp \times_{\mathrm{ev}_1 \circ \mathrm{ev}_1, D} {}_\natural C \longrightarrow {}_\natural E$$

over $\natural D$ (where $\mathcal{E}$ is the collection of edges e in $\mathcal{O}^{cocart}(D)$ such that $\mathrm{ev}_0(e)$ and $\mathrm{ev}_1(e)$ are cocartesian). We have a commutative square

$$\begin{array}{ccc} \mathcal{O}(\underline{x})^\sharp & \xrightarrow{\mathrm{ev}_0} & \underline{x}^\sharp \\ \downarrow{\scriptstyle \mathcal{O}(\mathrm{ev}_1)} & & \downarrow{\scriptstyle \mathrm{ev}_1} \\ (\mathcal{O}^{cocart}(D), \mathcal{E}) & \xrightarrow{\mathrm{ev}_0} & \natural D \end{array}$$

which defines the functor $\epsilon : \mathcal{O}(\underline{x}) \longrightarrow \underline{x} \times_D \mathcal{O}^{cocart}(D)$, and this in turn induces the functor ϵ^*. To show that ϵ^* is a cocartesian equivalence, it will suffice to show that ϵ is a trivial fibration, for then a choice of section σ and homotopy $\sigma \circ \epsilon \simeq \mathrm{id}$ will furnish a strong homotopy inverse to ϵ^* in the sense of [10, Proposition 3.1.3.5]. Since we have a pullback diagram

$$\begin{array}{ccc} \mathcal{O}(\underline{x}) & \longrightarrow & D \times_{\mathrm{Fun}(\Delta^1, D)} \mathrm{Fun}(\Delta^1 \times \Delta^1, D) \\ \downarrow{\scriptstyle \epsilon} & & \downarrow{\scriptstyle \epsilon'} \\ \underline{x} \times_D \mathcal{O}^{cocart}(D) & \longrightarrow & \mathrm{Fun}(\Lambda^2_1, D) \end{array}$$

it will further suffice to show that ϵ' is a trivial Kan fibration. ϵ' factors as the composition

$$D \times_{\mathrm{Fun}(\Delta^1, D)} \mathrm{Fun}(\Delta^1 \times \Delta^1, D) \xrightarrow{\epsilon''} \mathrm{Fun}(\Delta^2, D) \xrightarrow{\epsilon'''} \mathrm{Fun}(\Lambda^2_1, D)$$

where ϵ'' is defined by precomposing by the inclusion $i : \Delta^2 \longrightarrow \Delta^1 \times \Delta^1$ which avoids the degenerate edge for objects in $D \times_{\mathrm{Fun}(\Delta^1, D)} \mathrm{Fun}(\Delta^1 \times \Delta^1, D)$, and ϵ''' is precomposition by $\Lambda^2_1 \longrightarrow \Delta^2$. ϵ''' is a trivial fibration since $\Lambda^2_1 \longrightarrow \Delta^2$ is inner anodyne. To argue that ϵ'' is a trivial fibration, first note that ϵ'' inherits the property of being a categorical fibration from $i^* : \mathrm{Fun}(\Delta^1 \times \Delta^1, D) \longrightarrow \mathrm{Fun}(\Delta^2, D)$. Define an inverse σ'' by precomposing by the unique retraction $r : \Delta^1 \times \Delta^1 \longrightarrow \Delta^2$ chosen so that $r \circ i = \mathrm{id}$. Then σ'' is a section of ϵ'' and one can write down an explicit homotopy through equivalences of the identity functor on $D \times_{\mathrm{Fun}(\Delta^1, D)} \mathrm{Fun}(\Delta^1 \times \Delta^1, D)$ to $\sigma'' \circ \epsilon''$, so ϵ'' is a trivial fibration. □

D-parametrized slice. We now study another slice construction defined using the S-pairing construction.

9.8. **Construction.** Let $\phi : C \longrightarrow D$ be a S-cocartesian fibration, let $E \longrightarrow D$ be a S-fibration, and let $F : C \longrightarrow E$ be a S-functor over D. Then F defines a section S-functor

$$\tau_F : D \longrightarrow \widetilde{\mathrm{Fun}}_{D/S}(C, E)$$

as adjoint to the functor $\mathcal{O}^{cocart}(D) \times_{ev_1, D} C \longrightarrow C \xrightarrow{F} E$. Define

$$E^{(\phi,F)/S} := D \times_{\tau_F, \widetilde{\mathrm{Fun}}_{D/S}(C,E)} \widetilde{\mathrm{Fun}}_{D/S}(C \star_D D, E)$$

and let $\pi_{(\phi,F)}$ denote the projection $E^{(\phi,F)/S} \longrightarrow D$.

Given an object $x \in D$, the functor $\tau_F : D \longrightarrow \widetilde{\mathrm{Fun}}_{D/S}(C, E)$ induces via pullback a $\underline{x}$-functor

$$\tau_{F_{\underline{x}}} : \underline{x} \longrightarrow \widetilde{\mathrm{Fun}}_{D/S}(C, E)_{\underline{x}}.$$

We also have the $\underline{x}$-functor

$$\sigma_{F_{\underline{x}}} : \underline{x} \longrightarrow \underline{\mathrm{Fun}}_{\underline{x}}(C_{\underline{x}}, E_{\underline{x}})$$

adjoint to

$$\mathcal{O}(\underline{x}) \times_{\underline{x}} C_{\underline{x}} \xrightarrow{\mathrm{pr}_2} C_{\underline{x}} \xrightarrow{F_{\underline{x}}} E_{\underline{x}}.$$

An inspection of the definition of the comparison functor ϵ^* of 9.7 shows that the triangle

$$\begin{array}{ccc} \underline{x} & \xrightarrow{\tau_{F_{\underline{x}}}} & \widetilde{\mathrm{Fun}}_{D/S}(C, E)_{\underline{x}} \\ & \searrow{\scriptstyle \sigma_{F_{\underline{x}}}} & \downarrow{\scriptstyle \epsilon^*} \\ & & \underline{\mathrm{Fun}}_{\underline{x}}(C_{\underline{x}}, E_{\underline{x}}) \end{array}$$

commutes. Recalling the definitions

$$(E^{(\phi,F)/S})_{\underline{x}} = \underline{x} \times_{\widetilde{\mathrm{Fun}}_{D/S}(C,E)_{\underline{x}}} \widetilde{\mathrm{Fun}}_{D/S}(C \star_D D, E)_{\underline{x}},$$

$$(E_{\underline{x}})^{F_{\underline{x}}/\underline{x}} = \underline{x} \times_{\underline{\mathrm{Fun}}_{\underline{x}}(C_{\underline{x}},E_{\underline{x}})} \underline{\mathrm{Fun}}_{\underline{x}}(C_{\underline{x}} \star_{\underline{x}} \underline{x}, E_{\underline{x}}),$$

we therefore obtain a comparison $\underline{x}$-functor

$$\psi : (E^{(\phi,F)/S})_{\underline{x}} \longrightarrow (E_{\underline{x}})^{F_{\underline{x}}/\underline{x}}.$$

9.9. **Corollary.** *The functor ψ is a cocartesian equivalence in $s\mathbf{Set}^+_{/\underline{x}}$.*

Proof. By [10, Proposition 3.3.1.5], we have to verify that ψ induces a categorical equivalence on the fibers. But after passage to the fiber over an object $e = [x \longrightarrow y]$ in $\underline{x}$, by Lemma 4.8 ψ_e is a functor between two pullback squares in which one leg is a cartesian fibration. Therefore, by Proposition 9.7 and [10, Corollary 3.3.1.4], ψ_e is a categorical equivalence. □

9.10. **Proposition.** *Setup as in Construction 9.8, suppose in addition that $E \longrightarrow D$ is a S-cartesian fibration. Then $\pi_{(\phi,F)} : E^{(\phi,F)/S} \longrightarrow D$ is a S-cartesian fibration.*

Proof. By Lemma 9.4, $\pi_{(\phi,F)}$ is a categorical fibration. By Theorem 9.3, Lemma 9.4, and Lemma 4.8, the functor

$$(\iota_C^*)_s : \widetilde{\mathrm{Fun}}_{D/S}(C \star_D D, E)_s \longrightarrow \widetilde{\mathrm{Fun}}_{D/S}(C, E)_s$$

over D_s satisfies the hypotheses of [10, Proposition 2.4.2.11], hence is a locally cartesian fibration. To then show that $(\iota_C^*)_s$ is a cartesian fibration, it suffices to check that for every square

$$\begin{array}{ccc} \left[G : C_{\underline{x}} \star_{\underline{x}} \underline{x} \longrightarrow E_{\underline{x}}\right] & \longrightarrow & \left[G' : C_{\underline{y}} \star_{\underline{y}} \underline{y} \longrightarrow E_{\underline{y}}\right] \\ \downarrow & & \downarrow \\ \left[H : C_{\underline{x}} \star_{\underline{x}} \underline{x} \longrightarrow E_{\underline{x}}\right] & \longrightarrow & \left[H' : C_{\underline{y}} \star_{\underline{y}} \underline{y} \longrightarrow E_{\underline{y}}\right] \end{array}$$

in $\widetilde{\mathrm{Fun}}_{D/S}(C \star_D D, E)_s$ lying over an edge $e : x \longrightarrow y$ in D_s, if the horizontal edges are cartesian lifts over e and the right vertical edge is $(\iota_C^*)_{s,y}$-cartesian, then the left vertical edge is $(\iota_C^*)_{s,x}$-cartesian. In other words, if we let $e_! : C_{\underline{x}} \star_{\underline{x}} \underline{x} \longrightarrow C_{\underline{y}} \star_{\underline{y}} \underline{y}$ and $e^* : E_{\underline{y}} \longrightarrow E_{\underline{x}}$ denote choices of pushforward and pullback functors, then we want to show that given $G \simeq e^* \circ G' \circ e_!$, $H \simeq e^* \circ H' \circ e_!$, and $G'|_{\underline{y}} \simeq H'|_{\underline{y}}$, we have that $G|_{\underline{x}} \simeq H|_{\underline{x}}$. But this is clear. We deduce that $(\pi_{(\phi,F)})_s$, being pulled back from $(\iota_C^*)_s$, is a cartesian fibration.

For the final verification, let us abbreviate objects

$$(x \in D, \left[G : C_{\underline{x}} \star_{\underline{x}} \underline{x} \longrightarrow E_{\underline{x}}\right] : G|_{C_{\underline{x}}} = F_{\underline{x}}) \in E^{(\phi,F)/S}$$

as $\left[G : C_{\underline{x}} \star_{\underline{x}} \underline{x} \longrightarrow E_{\underline{x}}\right]$, the restriction to $C_{\underline{x}}$ equaling $F_{\underline{x}}$ being left implicit. We must check that given a square

$$\begin{array}{ccc} x & \xrightarrow{\widetilde{\alpha}_x} & x' \\ {\scriptstyle e}\downarrow & & \downarrow{\scriptstyle e'} \\ y & \xrightarrow{\widetilde{\alpha}_y} & y' \end{array}$$

in D lying over $\alpha : s \longrightarrow t$ with the vertical edges in the fiber and the horizontal edges cocartesian lifts of α, and given a lift of that square to a square

$$\begin{array}{ccc} \left[G : C_{\underline{x}} \star_{\underline{x}} \underline{x} \longrightarrow E_{\underline{x}}\right] & \longrightarrow & \left[G' : C_{\underline{x'}} \star_{\underline{x'}} \underline{x'} \longrightarrow E_{\underline{x'}}\right] \\ \downarrow & & \downarrow \\ \left[H : C_{\underline{y}} \star_{\underline{y}} \underline{y} \longrightarrow E_{\underline{y}}\right] & \longrightarrow & \left[H' : C_{\underline{y'}} \star_{\underline{y'}} \underline{y'} \longrightarrow E_{\underline{y'}}\right] \end{array}$$

in $E^{(\phi,F)/S}$ with the horizontal edges cocartesian lifts of α and the left vertical edge $(\pi_{(\phi,F)})_s$-cartesian, then the right vertical edge is $(\pi_{(\phi,F)})_t$-cartesian. We will once more translate this compatibility statement into a more obvious looking one so as to conclude. Let $e_!, e^*, e'_!, e'^*$ be defined as above. Let $\alpha^* : \underline{x'} \longrightarrow \underline{x}$, $\alpha^* : \underline{y'} \longrightarrow \underline{y}$ be choices of pullback functors (e.g. the first sends a cocartesian edge $f : x' \longrightarrow z$ to $f \circ \widetilde{\alpha}_x : x \longrightarrow z$), and also label related functors by α^*. Then the cocartesianness of the horizontal edges amounts to the equivalences $G' \simeq G \circ \alpha^*$ and $H' \simeq H \circ \alpha^*$, and the cartesianness of the left vertical edge amounts to the equivalence $G|_{\underline{x}} \simeq (e^* \circ H \circ e_!)|_{\underline{x}}$. Our desired assertion now is implied by the homotopy commutativity of the diagram

$$\begin{array}{ccccc} \underline{x'} & \xrightarrow{\alpha^*} & \underline{x} & \xrightarrow{G|_{\underline{x}}} & E_{\underline{x}} \\ \downarrow{\scriptstyle e'_!} & & \downarrow{\scriptstyle e_!} & & \uparrow{\scriptstyle e^*} \\ \underline{y'} & \xrightarrow{\alpha^*} & \underline{y} & \xrightarrow{H|_{\underline{y}}} & E_{\underline{y}} \end{array}$$

(the content being in the commutativity of the first square), for this demonstrates that $G'|_{\underline{x'}} \simeq (e'^* \circ H' \circ e'_!)|_{\underline{x'}}$. ∎

9.11. **Lemma.** *Let $p : W \longrightarrow S$, $q : D \longrightarrow S$ be S-categories and let $\pi : W \longrightarrow D$ be a S-fibration such that for every object $s \in S$, π_s is a cartesian fibration.*

(1) Suppose that:
   (a) For every object $x \in D$, there exists an initial object in W_x.
   (b) For every p-cocartesian edge $w \to w'$ in W, if w is an initial object in $W_{\pi(w)}$, then w' is an initial object in $W_{\pi(w')}$.

   Let $W' \subset W$ be the full simplicial subset of W spanned by those objects $w \in W$ which are initial in $W_{\pi(w)}$ and let $\pi' = \pi|_{W'}$. Then W' is a full S-subcategory of W and π' is a trivial fibration.

(2) Let $\sigma : D \longrightarrow W$ be a S-functor which is a section of π. Then σ is a left adjoint of π relative to D if and only if, for every object $x \in D$, $\sigma(x)$ is an initial object of W_x.

Proof. (1) Condition (b) ensures that W' is a S-subcategory of W. By [10, Proposition 2.4.4.9], for every object $s \in S$, π'_s is a trivial fibration. In particular, π' is S-cocartesian fibration (the compatibility condition being vacuous since all edges in W'_s are π'_s-cocartesian). By Remark 7.4, π' is a cocartesian fibration. As a cocartesian fibration with contractible fibers, π' is a trivial fibration.

(2) Since relative adjunctions are stable under base change, if σ is a left adjoint of π relative to D, passage to the fiber over $x \in D$ shows that $\sigma(x)$ is an initial object of W_x. Conversely, if for all $x \in D$, $\sigma(x)$ is an initial object of W_x, then by [10, Proposition 5.2.4.3], σ_s is left adjoint to π_s for all $s \in S$. Since σ is already given as a S-functor, this implies that σ is S-left adjoint to π; in particular, σ is left adjoint to π. The existence of σ implies the hypotheses of (1), so σ is fully faithful. Now by definition, σ is left adjoint to π relative to D.

∎

We now connect the construction $\widetilde{\mathrm{Fun}}_{D/S}(-,-)$ with $\underline{\mathrm{Fun}}_S(-,-)$. To this end, consider the commutative diagram

$$\begin{array}{ccccc} \mathcal{O}(S)^\sharp \times_S {}^\natural C & & \longrightarrow & & S^\sharp \\ & \searrow^{i} & & & \\ & \mathcal{O}(S)^\sharp \times_S (\mathcal{O}^{cocart}(D) \times_D C, \mathcal{E}) & \longrightarrow & (\mathcal{O}^{cocart}(D) \times_D C, \mathcal{E}) & \longrightarrow S^\sharp \\ & \downarrow & & \downarrow & \\ & \mathcal{O}(S)^\sharp \times_S {}^\natural D & \xrightarrow{\mathrm{pr}_D} & {}^\natural D & \\ & \downarrow{\scriptstyle \mathrm{ev}_0} & & & \\ & S^\sharp, & & & \end{array}$$

where the map i is induced by the identity section $D \longrightarrow \mathcal{O}^{cocart}(D)$.

9.12. **Lemma.** *i is a homotopy equivalence in $s\mathbf{Set}^+_{/S}$ (considered over S via $p : C \longrightarrow S$).*

Proof. Define a map $h' : \mathcal{O}(S) \times_S \mathcal{O}^{cocart}(D) \longrightarrow \mathrm{Fun}(\Delta^1, \mathcal{O}(S) \times_S \mathcal{O}^{cocart}(D))$ to be the product of the following three maps:

(1) Choose a lift σ

$$\begin{array}{ccc} \mathrm{Fun}(\Delta^{\{0,1\}}, S) & \xrightarrow{s_1} & \mathrm{Fun}(\Delta^2, S) \\ \downarrow & \overset{\sigma}{\nearrow} & \downarrow \sim \\ \mathrm{Fun}(\Lambda^2_1, S) & \xrightarrow{=} & \mathrm{Fun}(\Lambda^2_1, S) \end{array}$$

and let $\Delta^1 \times \Delta^1 \longrightarrow \Delta^2$ be the unique map so that the induced map $\mathrm{Fun}(\Delta^2, S) \longrightarrow \mathrm{Fun}(\Delta^1 \times \Delta^1, S) \cong \mathrm{Fun}(\Delta^1, \mathcal{O}(S))$ sends $(s \longrightarrow t \longrightarrow u)$ to $[s \longrightarrow t] \longrightarrow [s \longrightarrow u]$. Use these two maps to define

$$\mathcal{O}(S) \times_S \mathcal{O}^{cocart}(D) \times_D C \longrightarrow \mathcal{O}(S) \times_S \mathcal{O}(S) \cong \mathrm{Fun}(\Lambda^2_1, S) \longrightarrow \mathrm{Fun}(\Delta^1, \mathcal{O}(S)).$$

(2) Use the unique map $\Delta^1 \times \Delta^1 \longrightarrow \Delta^1$ which sends $(0,0)$ to 0 and all other vertices to 1 to define

$$\mathcal{O}(S) \times_S \mathcal{O}^{cocart}(D) \times_D C \longrightarrow \mathcal{O}^{cocart}(D) \longrightarrow \mathrm{Fun}(\Delta^1, \mathcal{O}^{cocart}(D)).$$

(3) The degeneracy map $s_0 : C \longrightarrow \mathrm{Fun}(\Delta^1, C)$ defines

$$\mathcal{O}(S) \times_S \mathcal{O}^{cocart}(D) \times_D C \longrightarrow C \longrightarrow \mathrm{Fun}(\Delta^1, C).$$

Then h' is adjoint to a map of marked simplicial sets over S

$$h : (\Delta^1)^\sharp \times \mathcal{O}(S)^\sharp \times_S (\mathcal{O}^{cocart}(D) \times_D C, \mathcal{E}) \longrightarrow \mathcal{O}(S)^\sharp \times_S (\mathcal{O}^{cocart}(D) \times_D C, \mathcal{E})$$

such that $h_0 = \mathrm{id}$ and h_1 factors as a composition

$$\mathcal{O}(S)^\sharp \times_S (\mathcal{O}^{cocart}(D) \times_D C, \mathcal{E}) \xrightarrow{r} \mathcal{O}(S)^\sharp \times_S {}_\natural C \xrightarrow{i} \mathcal{O}(S)^\sharp \times_S (\mathcal{O}^{cocart}(D) \times_D C, \mathcal{E})$$

where r is defined by

$$\mathcal{O}(S)^\sharp \times_S (\mathcal{O}^{cocart}(D) \times_D C, \mathcal{E}) \longrightarrow \mathrm{Fun}(\Lambda^2_1, S)^\sharp \times_S {}_\natural C \xrightarrow{d_1 \circ \sigma} \mathcal{O}(S)^\sharp \times_S {}_\natural C.$$

Our choice of σ ensures that $r \circ i = \mathrm{id}$, completing the proof. □

Note that for any S-fibration $\pi : X \longrightarrow D$, the S-category $\underline{\mathbf{Sect}}_{D/S}(\pi)$ defined in 8.6 may be identified with $(\mathrm{ev}_0)_*(\mathrm{pr}_D)^*({}_\natural X \xrightarrow{\pi} {}_\natural D)$. Combining Lemma 9.12, Lemma 2.27, and Lemma 2.28, we see that if E is a S-category and $C \longrightarrow D$ is S-cocartesian or S-cartesian, then the map induced by i

$$i^* : \underline{\mathbf{Sect}}_{D/S}(\widetilde{\mathrm{Fun}}_{D/S}(C, E \times_S D)) \longrightarrow \underline{\mathrm{Fun}}_S(C, E)$$

is a equivalence of S-categories. Moreover, a chase of the definitions reveals that for every S-functor $F : C \longrightarrow E$, we have an identification

$$i^* \circ \underline{\mathbf{Sect}}_{D/S}(\tau_{F \times \phi}) = \sigma_F : S \longrightarrow \underline{\mathrm{Fun}}_S(C, E).$$

We thus have a morphism of spans

$$\begin{array}{ccccc} S & \xrightarrow{\underline{\mathbf{Sect}}_{D/S}(\tau_{F\times\phi})} & \underline{\mathbf{Sect}}_{D/S}(\widetilde{\mathrm{Fun}}_{D/S}(C, E \times_S D)) & \longleftarrow & \underline{\mathbf{Sect}}_{D/S}(\widetilde{\mathrm{Fun}}_{D/S}(C \star_D D, E \times_S D)) \\ \downarrow = & & \downarrow \simeq & & \downarrow \simeq \\ S & \xrightarrow{\sigma_F} & \underline{\mathrm{Fun}}_S(C, E) & \longleftarrow & \underline{\mathrm{Fun}}_S(C \star_D D, E). \end{array}$$

The right horizontal maps are S-fibrations by Lemma 9.4 and [3, Proposition 9.11(2)], so taking pullbacks yields an equivalence

$$\underline{\mathbf{Sect}}_{D/S}((E \times_S D)^{(\phi, F\times\phi)/S}) \xrightarrow{\simeq} S \times_{\sigma_F, \underline{\mathrm{Fun}}_S(C,E)} \underline{\mathrm{Fun}}_S(C \star_D D, E). \tag{9.12.1}$$

We are now prepared to introduce the main definition of this section.

9.13. **Definition.** Let $\phi : C \longrightarrow D$ be a S-cocartesian fibration. A S-functor $\overline{F} : C \star_D D \longrightarrow E$ is a *D-parametrized S-colimit diagram* if for every object $x \in D$, the $\underline{x}$-functor $\overline{F}|_{C_{\underline{x}} \star_{\underline{x}} \underline{x}} : C_{\underline{x}} \star_{\underline{x}} \underline{x} \longrightarrow E_{\underline{s}}$ is a $\underline{s}$-colimit diagram.

9.14. **Proposition.** *Let $\phi : C \longrightarrow D$ be a S-cocartesian fibration, let $F : C \longrightarrow E$ be a S-functor, and let $\overline{F} : C \star_D D \longrightarrow E$ be a D-parametrized S-colimit diagram extending F. Then the section*

$$\mathrm{id}_S \times \sigma_{\overline{F}} : S \longrightarrow S \times_{\sigma_F, \underline{\mathrm{Fun}}_S(C,E)} \underline{\mathrm{Fun}}_S(C \star_D D, E)$$

is a S-initial object.

Proof. Combine Equation 9.12.1, Lemma 9.11(2), and Corollary 8.7. □

We have the following existence and uniqueness result for D-parametrized S-colimits.

9.15. **Theorem.** *Let $\phi : C \longrightarrow D$ be a S-cocartesian fibration and let $F : C \longrightarrow E$ be a S-functor. Suppose that for every object $x \in D$, the $\underline{s}$-functor $F|_{C_{\underline{x}}} : C_{\underline{x}} \longrightarrow E_{\underline{s}}$ admits a $\underline{s}$-colimit. Then there exists a D-parametrized S-colimit diagram $\overline{F} : C \star_D D \longrightarrow E$ extending F. Moreover, the full subcategory of $\{F\} \times_{\mathrm{Fun}_S(C,E)} \mathrm{Fun}_S(C \star_D D, E)$ spanned by the D-parametrized S-colimit diagrams coincides with that spanned by the initial objects.*

Proof. By Proposition 9.10 and Corollary 9.9, the functor

$$\pi_{(\phi, F\times\phi)} : (E \times_S D)^{(\phi, F\times\phi)/S} \longrightarrow D$$

is a S-cartesian fibration with $\underline{x}$-fibers equivalent to $(E_{\underline{s}})^{(F|_{C_{\underline{x}}}, \underline{s})/}$. Our hypothesis ensures that the conditions of Lemma 9.11(1) are satisfied, so $\pi_{(\phi,F\times\phi)}$ admits a section σ which is a S-functor that selects an initial object in each fiber. The resulting S-functor $D \longrightarrow \widetilde{\mathrm{Fun}}_{D/S}(C \star_D D, E \times_S D)$ covering $\tau_{F\times\phi}$ is adjoint to a S-functor $\overline{F} : C \star_D D \longrightarrow E$ extending F, which is a D-parametrized S-colimit diagram. Having proven existence, the second statement now follows from Proposition 9.14. □

Theorem 9.15 also admits the following 'global' consequence.

9.16. **Corollary.** *Let $\phi : C \longrightarrow D$ be a S-cocartesian fibration and E be an S-category. Suppose that for every $s \in S$ and $x \in D_s$, $E_{\underline{s}}$ admits all $S^{s/}$-colimits of shape $C_{\underline{x}}$. Then $U : \underline{\mathrm{Fun}}_S(C \star_D D, E) \longrightarrow \underline{\mathrm{Fun}}_S(C, E)$ admits a left S-adjoint L which is a section of U such that for every object $F : C_{\underline{s}} \longrightarrow E_{\underline{s}}$, $L(F)$ is a $D_{\underline{s}}$-parametrized $S^{s/}$-colimit diagram.*

Proof. By Example 7.10, Theorem 9.15 and the stability of parametrized colimit diagrams under base change, the conditions of Lemma 9.11(1) are satisfied for U. Thus U admits a section L which selects an initial object in each fiber, necessarily a parametrized colimit diagram. By Lemma 9.11(2), L is a left adjoint of U relative to $\underline{\mathrm{Fun}}_S(C, E)$; in particular, L is S-left adjoint to U. □

Application: Functor categories.

9.17. **Proposition.** *Let K, I, and C be S-categories.*

1. *Suppose that for all $s \in S$, $C_{\underline{s}}$ admits all $K_{\underline{s}}$-indexed colimits. $\overline{p} : K \star_S S \longrightarrow \underline{\mathrm{Fun}}_S(I, C)$ is a S-colimit diagram if and only if, for every object $x \in I$ over s,*

$$K_{\underline{s}} \star_{\underline{s}} \underline{s} \xrightarrow{\overline{p}_{\underline{s}}} \underline{\mathrm{Fun}}_{\underline{s}}(I_{\underline{s}}, C_{\underline{s}}) \xrightarrow{\mathrm{ev}_x} C_{\underline{s}}$$

   is a $S^{s/}$-colimit diagram.
2. *A S-functor $p : K \longrightarrow \underline{\mathrm{Fun}}_S(I, C)$ admits an extension to a S-colimit diagram $\overline{p}$ if for all $x \in I$, $\mathrm{ev}_x \circ p_{\underline{s}}$ admits an extension to a $S^{s/}$-colimit diagram.*

Proof. We prove (1), the proof for (2) being similar. Let

$$\overline{p'} : (K \times_S I) \star_I I \cong (K \star_S S) \times_S I \longrightarrow C$$

be a choice of adjoint of p under the equivalence

$$\mathrm{Fun}_S(K \star_S S, \underline{\mathrm{Fun}}_S(I, C)) \simeq \mathrm{Fun}_S((K \star_S S) \times_S I, C).$$

By Theorem 9.15 applied to the S-cocartesian fibration $K \times_S I \longrightarrow I$ and the hypothesis on C, there exists an I-parametrized S-colimit diagram p'' extending $p' = \overline{p'}|_{K \times_S I}$. By Proposition 9.14, p'' defines an S-initial object in

$$S \times_{\underline{\mathrm{Fun}}_S(K \times_S I, C)} \underline{\mathrm{Fun}}_S((K \times_S I) \star_I I, C) \simeq \underline{\mathrm{Fun}}_S(I, C)^{(p,S)/}$$

so *its* adjoint is a S-colimit diagram. For the 'if' direction, supposing that $\overline{p}$ is a S-colimit diagram, then by the uniqueness of S-initial objects, p'' is equivalent to $\overline{p'}$. Then $\mathrm{ev}_x \circ \overline{p}_{\underline{s}}$ is equivalent to $p''_{\underline{x}}$, which is a $S^{s/}$-colimit diagram by definition of I-parametrized S-colimit diagram. For the 'only if' direction, supposing that all the $\mathrm{ev}_x \, \overline{p}_{\underline{s}}$ are $S^{s/}$-colimit diagrams, we get that $\overline{p'}$ is a I-parametrized S-colimit diagram, so is equivalent to p''. □

9.18. **Corollary.** *Suppose C is S-cocomplete and I is a S-category. Then $\underline{\mathrm{Fun}}_S(I, C)$ is S-cocomplete.*

10. Kan extensions

We now combine the theory of S-colimits parametrized by a base S-category D and that of free S-cocartesian fibrations to establish the theory of left S-Kan extensions.

10.1. **Definition.** Suppose a diagram of S-categories

$$\begin{array}{ccc} C & \xrightarrow{\quad F \quad} & E \\ {\scriptstyle \phi}\big\downarrow & {\scriptstyle \eta}\Downarrow \nearrow_{G} & \\ D & & \end{array}$$

where by the '2-cell' η we mean exactly the datum of a S-functor $\eta : C \times \Delta^1 \longrightarrow E$ restricting to F on 0 and $G \circ \phi$ on 1. Let

$$G' : (C \times_D \mathcal{O}_S(D)) \star_D D \xrightarrow{\pi_D} D \xrightarrow{G} E,$$

let

$$\theta : (C \times_D \mathcal{O}_S(D)) \times \Delta^1 \longrightarrow E$$

be the natural transformation adjoint to $G_* : C \times_D \mathcal{O}_S(D) \longrightarrow \mathcal{O}_S(E)$, let

$$\eta' : (C \times_D \mathcal{O}_S(D)) \times \Delta^1 \longrightarrow C \times \Delta^1 \xrightarrow{\eta} E$$

be the natural transformation obtained from η, and let $\theta' = \theta \circ \eta'$ be a choice of composition in $\mathrm{Fun}_S(C \times_D \mathcal{O}_S(D), E)$. Let

$$r : \mathrm{Fun}_S((C \times_D \mathcal{O}_S(D)) \star_D D, E) \longrightarrow \mathrm{Fun}_S(C \times_D \mathcal{O}_S(D), E)$$

denote the restriction functor. By Lemma 4.8, we may select a r-cartesian edge e in $\mathrm{Fun}_S((C \times_D \mathcal{O}_S(D)) \star_D D, E)$ with $d_0(e) = G'$ covering θ', chosen so that $e|_D$ is degenerate. Let $G'' = d_1(e)$.

We say that G is a *left S-Kan extension* of F along ϕ if G'' is a D-parametrized S-colimit diagram.

10.2. **Remark.** The following are equivalent:

(1) G is a left S-Kan extension of F along ϕ.
(2) For all $s \in S$, $G_{\underline{s}}$ is a left $S^{s/}$-Kan extension of $F_{\underline{s}}$ along $\phi_{\underline{s}}$.
(3) For all $s \in S$ and $x \in D_s$, $G|_{\underline{x}} : \underline{x} \longrightarrow E_{\underline{s}}$ is a left $S^{s/}$-Kan extension of $F|_{C_{\underline{x}}} : C_{\underline{x}} \longrightarrow E_{\underline{s}}$ along $\phi_{\underline{x}} : C_{\underline{x}} \longrightarrow \underline{x}$.

In other words, our notion of S-Kan extension generalizes the concept of *pointwise* Kan extensions.

We can bootstrap Theorem 9.15 to prove existence and uniqueness of left S-Kan extensions.

10.3. **Theorem.** *Let $\phi : C \longrightarrow D$ and $F : C \longrightarrow E$ be S-functors. Suppose that for every object $x \in D$, the $S^{s/}$-functor*

$$C \times_D D^{/\underline{x}} \longrightarrow C_{\underline{s}} \xrightarrow{F_{\underline{s}}} E_{\underline{s}}$$

admits a $S^{s/}$-colimit. Then there exists a left S-Kan extension $G : D \longrightarrow E$ of F along ϕ, uniquely specified up to contractible choice.

Proof. We spell out the details of existence and leave the proof of uniqueness to the reader. By Theorem 9.15, there exists a D-parametrized S-colimit diagram

$$\overline{F} : (C \times_D \mathcal{O}_S(D)) \star_D D \longrightarrow E$$

extending $C \times_D \mathcal{O}_S(D) \longrightarrow C \xrightarrow{F} E$. Let $G = \overline{F}|_D$. Define a map

$$h : C \times \Delta^1 \longrightarrow (C \times_D \mathcal{O}_S(D)) \star_D D$$

over $D \times \Delta^1$ as adjoint to $(C \xrightarrow{(\mathrm{id}, \iota\phi)} C \times_D \mathcal{O}_S(D), C \xrightarrow{\phi} D)$ and let $\eta = \overline{F} \circ h$, so that η is a natural transformation from F to $G \circ \phi$.

We claim that η exhibits G as a left Kan extension of F along ϕ. To show this, we will exhibit a r-cartesian edge e from $\overline{F}$ to G' such that the restriction $r(e)$ of e to $C \times_D \mathcal{O}_S(D)$ is a choice of composition $\theta \circ \eta'$. Define

$$e' : (C \times_D \mathcal{O}_S(D)) \star_D D \times \Delta^1 \longrightarrow (C \times_D \mathcal{O}_S(D)) \star_D D$$

over $D \times \Delta^1$ as adjoint to (id, π_D), and let $e = \overline{F} \circ e'$, so that e is an edge from $\overline{F}$ to G'. Since $(\pi_D)|_D = \mathrm{id}_D$, $e|_D$ is a degenerate edge in $\mathrm{Fun}_S(D, E)$, so e is r-cartesian.

To finish the proof, we need to introduce a few more maps. Define

$$\alpha = (\mathrm{pr}_C, \alpha') : C \times_D \mathcal{O}_S(D) \times \Delta^1 \longrightarrow C \times_D \mathcal{O}_S(D)$$

where α' is adjoint to

$$C \times_D \mathcal{O}_S(D) \longrightarrow \mathcal{O}_S(D) = \widetilde{\mathrm{Fun}}_S(S \times \Delta^1, D) \xrightarrow{\min^*} \widetilde{\mathrm{Fun}}_S(S \times \Delta^1 \times \Delta^1, D).$$

Here $\min : \Delta^1 \times \Delta^1 \longrightarrow \Delta^1$ is the functor which takes the minimum. Define

$$\beta : C \times_D \mathcal{O}_S(D) \times \Delta^1 \longrightarrow \mathcal{O}_S(D) \times \Delta^1 \xrightarrow{\mathrm{ev}} D.$$

Use α and β to define

$$\gamma : C \times_D \mathcal{O}_S(D) \times \Delta^1 \times \Delta^1 \longrightarrow (C \times_D \mathcal{O}_S(D)) \star_D D$$

so that on objects $(c, \phi c \xrightarrow{f} d)$, γ sends $\Delta^1 \times \Delta^1$ to the square

$$\begin{array}{ccc} (c, \phi c = \phi c) & \longrightarrow & \phi c \\ \downarrow{\scriptstyle (\mathrm{id}, f)} & & \downarrow{\scriptstyle f} \\ (c, \phi c \xrightarrow{f} d) & \longrightarrow & d. \end{array}$$

Then $\overline{F} \circ \gamma$ defines a square

$$\begin{array}{ccc} F \circ \mathrm{pr}_C & \xrightarrow{\eta'} & G \circ \phi \circ \mathrm{pr}_C \\ \downarrow{\scriptstyle =} & & \downarrow{\scriptstyle \theta} \\ F \circ \mathrm{pr}_C & \xrightarrow{r(e)} & G'. \end{array}$$

in $\mathrm{Fun}_S(C \times_D \mathcal{O}_S(D), E)$, which proves that $r(e) \simeq \theta \circ \eta'$. □

We also have the Kan extension counterpart to Corollary 9.16.

10.4. **Definition.** Let $\phi : C \longrightarrow D$ be a S-functor and E a S-category. We say that E *admits the relevant S-colimits for ϕ* if for every $s \in S$ and $x \in D_s$, $E_{\underline{s}}$ admits all $S^{s/}$-colimits of shape $C \times_D D^{/\underline{x}}$.

10.5. **Theorem.** *Let $\phi : C \longrightarrow D$ be a S-functor and E a S-category. Suppose that E admits the relevant S-colimits for ϕ. Then the S-functor*

$$\phi^* : \underline{\mathrm{Fun}}_S(D, E) \longrightarrow \underline{\mathrm{Fun}}_S(C, E)$$

given by restriction along ϕ admits a left S-adjoint $\phi_!$ such that for every S-functor $F : C \longrightarrow E$, the unit map $F \longrightarrow \phi^* \phi_! F$ exhibits $\phi_! F$ as a left S-Kan extension of F along ϕ.

Proof. Factor ϕ as the composition

$$C \xrightarrow{\iota_C} C \times_D \mathcal{O}_S(D) \xrightarrow{i} (C \times_D \mathcal{O}_S(D)) \star_D D \xrightarrow{\pi_D} D.$$

Then ϕ^* factors as the composition

$$\underline{\mathrm{Fun}}_S(D, E) \xrightarrow{\pi_D^*} \underline{\mathrm{Fun}}_S((C \times_D \mathcal{O}_S(D)) \star_D D, E) \xrightarrow{i^*} \underline{\mathrm{Fun}}_S(C \times_D \mathcal{O}_S(D), E) \xrightarrow{\iota_C^*} \underline{\mathrm{Fun}}_S(C, E).$$

By Proposition 8.10 and Corollary 8.5, pr_C^* is left S-adjoint to ι_C^*. Since i_D is right S-adjoint to π_D, by Corollary 8.5 again i_D^* is left S-adjoint to π_D^*. By Corollary 9.16, i^* admits a left S-adjoint L which extends functors to D-parametrized S-colimit diagrams. Let $\phi_!$ be the composite of these three functors. The proof of Theorem 10.3 shows that $\phi_!(F)$ is as asserted. □

The next proposition permits us to eliminate the datum of the natural transformation η from the definition of a left S-Kan extension when ϕ is fully faithful.

10.6. **Proposition.** *Suppose $\phi : C \longrightarrow D$ is the inclusion of a full S-subcategory. Then for any left S-Kan extension G of $F : C \longrightarrow E$ along ϕ, η is a natural transformation through equivalences. Consequently, G is homotopic to a functor $\overline{F} : D \longrightarrow E$ which is both an extension of F and a left S-Kan extension (with the natural transformation $F \longrightarrow \overline{F} \circ \phi = F$ chosen to be the identity).*

Proof. Let $G'' : (C \times_D \mathcal{O}_S(D)) \star_D D \longrightarrow E$ be as in the definition of a left S-Kan extension. Because D-parametrized S-colimit diagrams are stable under restriction to S-subcategories,

$$(G'')_C : (C \times_D \mathcal{O}_S(D) \times_D C) \star_C C \longrightarrow E$$

is a C-parametrized S-colimit diagram. The additional assumption that C is a full S-subcategory has the consequence that $(C \times_D \mathcal{O}_S(D) \times_D C) \cong \mathcal{O}_S(C)$. Also, for any object $x \in C$, the inclusion $\underline{x}$-functor $i_x : \underline{x} \longrightarrow C^{/\underline{x}}$ is $\underline{x}$-final, using the first criterion of Theorem 6.7. Therefore, $\mathcal{O}_S(C) \star_C C \xrightarrow{\pi_C} C \xrightarrow{F} E$ is a C-parametrized S-colimit diagram extending $\mathcal{O}_S(C) \xrightarrow{\mathrm{ev}_0} C \xrightarrow{F} E$, so $(G'')_C \simeq F \circ \pi_C$.

The map h in the proof of Theorem 10.3 factors as

$$C \times \Delta^1 \xrightarrow{h'} \mathcal{O}_S(C) \star_C C \longrightarrow (C \times_D \mathcal{O}_S(D)) \star_D D.$$

We have the chain of equivalences

$$\eta \simeq G'' \circ h \simeq F \circ \pi_C \circ h' = F \circ \mathrm{pr}_C,$$

proving the first assertion. For the second assertion, use that

$$(\natural D \times \{1\}) \cup_{\natural C \times \{1\}} (\natural C \times (\Delta^1)^\sharp) \longrightarrow \natural D \times (\Delta^1)^\sharp$$

is a cocartesian equivalence in $s\mathbf{Set}^+_{/S}$ to extend (G, η) to a homotopy between G and an extension $\overline{F}$, which is then necessarily a left S-Kan extension. □

10.7. **Corollary.** *Suppose $\phi : C \longrightarrow D$ a fully faithful S-functor and E a S-cocomplete S-category. Then the left S-adjoint $\phi_!$ to the restriction S-functor ϕ^* exists and is fully faithful.*

Proof. Combine Theorem 10.5 and Proposition 10.6. □

As expected, S-colimit diagrams are examples of S-left Kan extensions.

10.8. **Proposition.** *Suppose $\phi : C \longrightarrow D$ a S-cocartesian fibration and $\overline{F} : C \star_D D \longrightarrow E$ a S-functor extending $F : C \longrightarrow E$. Then $\overline{F}$ is a D-parametrized S-colimit diagram if and only if $\overline{F}$ is a S-left Kan extension of F.*

Proof. We may check the assertion objectwise on D, so let $x \in D_s$. Consider the commutative diagram

$$\begin{array}{ccc} C_{\underline{x}} & \hookrightarrow & C_{\underline{s}} \\ {\scriptstyle\theta}\downarrow & \nearrow{\scriptstyle \mathrm{pr}_C} & \downarrow{\scriptstyle F_{\underline{s}}} \\ C \times_{C \star_D D} (C \star_D D)^{/\underline{x}} & \longrightarrow & E_{\underline{s}}. \end{array}$$

The value of a D-parametrized colimit of F on x is computed as the $S^{s/}$-colimit of $(F_{\underline{s}})|_{C_{\underline{x}}}$, and that of a S-left Kan extension of F as the $S^{s/}$-colimit of $F_{\underline{s}} \circ \mathrm{pr}_C$. Therefore, it suffices to prove that θ is

$\underline{x}$-final. Let $f : x \to y$ be an object in $\underline{x}$, i.e. a cocartesian edge in D, which lies over $s \longrightarrow t$. Then θ_f is equivalent to the inclusion

$$C_y \cong C_y \times_{(C_y)^{\rhd}} ((C_y)^{\rhd})^{/\{\infty\}} \longrightarrow C_t \times_{C_t \star_{D_t} D_t} (C_t \star_{D_t} D_t)^{/y}.$$

Applying Lemma 10.9 to the map $C_t \longrightarrow C_t \star_{D_t} D_t$ of cocartesian fibrations over D_t, we deduce that θ_f is final. □

10.9. **Lemma.** *Let $X \longrightarrow Y$ be a map of cocartesian fibrations over Z and let $y \in Y$ be an object over $z \in S$. Then the inclusion $X_z \times_{Y_z} Y_z^{/y} \longrightarrow X \times_Y Y^{/y}$ is final.*

Proof. By the dual of [12, Lemma 3.4.1.10], $X \times_Y Y^{/y} \longrightarrow Z^{/z}$ is a cocartesian fibration. We have a pullback square

$$\begin{array}{ccc} X_z \times_{Y_z} Y_z^{/y} & \longrightarrow & X \times_Y Y^{/y} \\ \big\downarrow & & \big\downarrow \\ \{z\} & \xrightarrow{\mathrm{id}_z} & Z^{/z}. \end{array}$$

Since the bottom horizontal map is final and cocartesian fibrations are smooth, the top horizontal map is final. □

As with S-colimits, S-left Kan extensions reduce to the usual notion of left Kan extension when taken in a S-category of objects.

10.10. **Proposition.** *Suppose a diagram of S-categories*

$$\begin{array}{ccc} C & \xrightarrow{F} & \underline{E}_S \\ {\scriptstyle\phi}\big\downarrow & \overset{\eta}{\Downarrow} \nearrow_{G} & \\ D & & \end{array}.$$

The following are equivalent:

1. *(1) G is a left S-Kan extension of F along ϕ.*
2. *(2) $G^\dagger$ is a left Kan extension of $F^\dagger$ along ϕ.*
3. *(3) For all objects $s \in S$, $G^\dagger|_{D_s}$ is a left Kan extension of $F^\dagger|_{C_s}$ along ϕ_s.*

Proof. We first prove that (1) and (2) are equivalent. Factor $\phi : C \longrightarrow D$ through the free S-cocartesian fibration on ϕ:

$$\phi : C \xrightarrow{\iota_C} C \times_D \mathcal{O}_S D \xrightarrow{\mathrm{Fr}^{cocart}(\phi)} D.$$

Since ι_C is S-left adjoint to pr_C, it is also left adjoint. Therefore, the S-left Kan extension resp. the left Kan extension of F resp. $F^\dagger$ along ι_C is computed by $F \circ \mathrm{pr}_C$ resp. $F^\dagger \circ \mathrm{pr}_C$. By transitivity of Kan extensions, we thereby reduce to the case that ϕ is S-cocartesian. The claim now follows easily by combining Proposition 5.5 and Proposition 10.8.

We next prove that (2) and (3) are equivalent. For this, it suffices to observe that for all objects $d \in D$ over some $s \in S$, $C_s \times_{D_s} D_s^{/d} \longrightarrow C \times_D D^{/d}$ is final by Lemma 10.9 applied to $C \longrightarrow D$. □

11. Yoneda lemma

By Proposition 5.5, $\underline{\mathbf{Spc}}_S$ is S-cocomplete, so by Corollary 9.18, the S-category of presheaves

$$\mathbf{P}_S(C) := \underline{\mathrm{Fun}}_S(C^{vop}, \underline{\mathbf{Spc}}_S)$$

is S-cocomplete. The S-Yoneda embedding $j : C \longrightarrow \mathbf{P}_S(C)$ was constructed in [3, §10] via S-straightening the left fibration $\widetilde{\mathcal{O}}_S(C) \longrightarrow C^{vop} \times_S C$ given fiberwise by twisted arrows. It was shown there that j is fully faithful [2, Theorem 10.4]. In this section, we first prove the S-Yoneda lemma and then establish the universal property of $\mathbf{P}_S(C)$ as the free S-cocompletion of C.

11.1. **Lemma** (S-Yoneda lemma)**.** *Let $j : C \longrightarrow \mathbf{P}_S(C)$ denote the S-Yoneda embedding. Then the identity on $\mathbf{P}_S(C)$ is a S-left Kan extension of j along itself.*

Proof. By Proposition 9.17, it suffices to show that for every $s \in S$ and object $x \in C_s$, $\mathrm{ev}_x : \mathbf{P}_{\underline{s}}(C_{\underline{s}}) \longrightarrow \underline{\mathbf{Spc}}_{\underline{s}}$ is a $S^{s/}$-left Kan extension of $\mathrm{ev}_x\, j_{\underline{s}}$. To ease notation, let us replace $S^{s/}$ by S and suppose that $s \in S$ is an initial object.

We claim that $(\mathrm{ev}_x\, j)^\dagger : C \longrightarrow \mathbf{Spc}$ is homotopic to $\mathrm{Map}_C(x, -)$. By definition of the S-Yoneda embedding, $(\mathrm{ev}_x\, j)^\dagger$ classifies the left fibration

$$\mathrm{ev}_1 : \widetilde{\mathcal{O}}_S(C)_{x\to} \longrightarrow C$$

pulled back from $\widetilde{\mathcal{O}}_S(C) \longrightarrow C^{vop} \times_S C$ via the cocartesian section $\sigma : S \longrightarrow C^{vop}$ defined by $\sigma(s) = x$. By [10, Proposition 4.4.4.5], it suffices to show that id_x is an initial object in $\widetilde{\mathcal{O}}_S(C)_{x\to}$. For this, because $s \in S$ is an initial object we reduce to checking that for all edges $\alpha : s \to t$, the pushforward of id_x by α is an initial object in the fiber $(\widetilde{\mathcal{O}}_S(C)_{x\to})_t$. But this fiber is equivalent to $\widetilde{\mathcal{O}}(C_t)_{\alpha_! x\to} \simeq (C_t)^{\alpha_! x/}$.

Applying Proposition 10.10, we reduce to showing that for all $t \in S$, $(\mathrm{ev}_x)^\dagger|_{\mathbf{P}_S(C)_t}$ is a left Kan extension of $(\mathrm{ev}_x\, j)^\dagger|_{C_t}$. Note that for y any cocartesian pushforward of x over the essentially unique edge $s \to t$, we have both that $(\mathrm{ev}_x\, j)^\dagger|_{C_t}$ is homotopic to $\mathrm{Map}_{C_t}(y, -)$ and $(\mathrm{ev}_x)^\dagger|_{\mathbf{P}_S(C)_t}$ is homotopic to ev_y (regarding y as an object in $C_{\underline{t}}^{vop}$). The inclusion

$$C_t \longrightarrow \mathbf{P}_S(C)_t \simeq \mathrm{Fun}(C_{\underline{t}}^{vop}, \mathbf{Spc})$$

factors through $\mathbf{P}(C_t)$ with $\mathbf{P}(C_t) \longrightarrow \mathrm{Fun}(C_{\underline{t}}^{vop}, \mathbf{Spc})$ left adjoint to precomposition by the inclusion $i : C_t^{op} \longrightarrow C_{\underline{t}}^{vop}$. By the usual Yoneda lemma for ∞-categories, $\mathrm{ev}_y : \mathbf{P}(C_t) \longrightarrow \mathbf{Spc}$ is the left Kan extension of $\mathrm{Map}_{C_t}(y, -)$. The left Kan extension of ev_y to $\mathbf{P}_S(C)_t$ is then given by precomposition by i, so is again ev_y. □

To state the universal property of $\mathbf{P}_S(C)$, we need to introduce a bit of terminology.

11.2. **Definition.** Let $F : C \longrightarrow D$ be a S-functor. We say that F *strongly preserves S-(co)limits* if for all $s \in S$, $F_{\underline{s}}$ preserves $S^{s/}$-(co)limits.

11.3. **Remark.** If F strongly preserves S-colimits then F preserves S-colimits. However, the converse is not necessarily true.

11.4. **Notation.** Suppose that C and D are S-cocomplete S-categories. Let $\mathrm{Fun}^L_S(C, D)$ denote the full subcategory of $\mathrm{Fun}_S(C, D)$ on the S-functors F which strongly preserve S-colimits. Let $\underline{\mathrm{Fun}}^L_S(C, D)$ denote the full S-subcategory of $\underline{\mathrm{Fun}}_S(C, D)$ with fibers $\mathrm{Fun}^L_{S^{s/}}(C, D)$ over $s \in S$.

11.5. **Theorem.** *Let E be a S-cocomplete S-category. Then restriction along the S-Yoneda embedding defines equivalences*

$$\mathrm{Fun}^L_S(\mathbf{P}_S(C), E) \xrightarrow{\simeq} \mathrm{Fun}_S(C, E)$$
$$\underline{\mathrm{Fun}}^L_S(\mathbf{P}_S(C), E) \xrightarrow{\simeq} \underline{\mathrm{Fun}}_S(C, E)$$

with the inverse given by S-left Kan extension.

We prepare for the proof of Theorem 11.5 with some necessary results concerning S-mapping spaces. Recall that given an ∞-category C, we have a number of equivalent options for describing mapping spaces in C. The relevant ones to consider for us are:

(1) Straightening the left fibration $\widetilde{\mathcal{O}}(C) \longrightarrow C^{op} \times C$, we obtain the mapping space functor
$$\mathrm{Map}_C(-, -) : C^{op} \times C \longrightarrow \mathbf{Spc};$$
(2) Fixing an object $x \in C$, straightening the left fibration $C^{x/} \longrightarrow C$ also yields the functor
$$\mathrm{Map}_C(x, -) : C \longrightarrow \mathbf{Spc};$$
(3) Fixing objects $x, y \in C$, we have that the space $\mathrm{Map}_C(x, y)$ is given by
$$\{x\} \times_C \mathcal{O}(C) \times_C \{y\}.$$

Likewise, given a S-category C, we have these possibilities:

(1) The S-functor
$$\underline{\mathrm{Map}}_C(-,-) : C^{vop} \times_S C \longrightarrow \underline{\mathbf{Spc}}_S$$
given by the S-straightening of $\widetilde{\mathcal{O}}_S(C) \longrightarrow C^{vop} \times_S C$;

(2) Fixing an object $x \in C$, we have the left fibration $C^{\underline{x}/} = \underline{x} \times_C \mathcal{O}_S(C) \longrightarrow C$, which S-straightens to
$$\underline{\mathrm{Map}}_C(x,-) : C \longrightarrow \underline{\mathbf{Spc}}_S;$$

(3) Fixing an object $x \in C$, we have the left fibration $C^{x/} \longrightarrow C$, which S-straightens to
$$\underline{\mathrm{Map}}_C(x,-) : C \longrightarrow \underline{\mathbf{Spc}}_S;$$

(4) Fixing objects $x \in C$ and $y \in C_s$, we have the $S^{s/}$-space
$$\underline{\mathrm{Map}}_C(x,y) = \underline{x} \times_C \mathcal{O}_S(C) \times_C \underline{y} \longrightarrow \underline{y} \xrightarrow{\simeq} S^{s/}.$$

In the proof of Lemma 11.1, we showed that (1) and (3) were equivalent, and by Proposition 4.31, (2) and (3) are equivalent. Finally, (2) specializes to (4) by definition. We are thus justified in our abuse of notation when we interchangeably refer to any of these options by $\underline{\mathrm{Map}}_C(-,-)$.

Our next goal is to prove that $\underline{\mathrm{Map}}_C(-,-)$ preserves S-limits in the second variable, and dually, takes S-colimits in the first variable to S-limits. For this, we need a few lemmas.

11.6. **Lemma.** *Let $F : X \longrightarrow Y$ be a map of S-cocartesian or S-cartesian fibrations over an S-category C. The following are equivalent:*

(1) F is an equivalence.

(2) For all $s \in S$ and $S^{s/}$-functors $Z \longrightarrow C_{\underline{s}}$,
$$\underline{\mathrm{Fun}}_{/C_{\underline{s}},S^{s/}}(Z, X_{\underline{s}}) \longrightarrow \underline{\mathrm{Fun}}_{/C_{\underline{s}},S^{s/}}(Z, Y_{\underline{s}})$$
is an equivalence.

(3) For all $s \in S$ and $c \in C_s$,
$$\underline{\mathrm{Fun}}_{/C_{\underline{s}},S^{s/}}(\underline{c}, X_{\underline{s}}) \longrightarrow \underline{\mathrm{Fun}}_{/C_{\underline{s}},S^{s/}}(\underline{c}, Y_{\underline{s}})$$
is an equivalence.

(4) For all $c \in C$, $F_c : X_c \longrightarrow Y_c$ is an equivalence.

If X and Y are S-left or S-right fibrations over C, then all instances of $\underline{\mathrm{Fun}}$ can be replaced by $\underline{\mathrm{Map}}$.[19]

Proof. (1) ⇒ (2): If F is an equivalence, so is $F_{\underline{s}}$ for all $s \in S$. The map in question is then induced by a map of pullbacks through equivalences in which two matching legs are S-fibrations, so is an equivalence.

(2) ⇒ (3) is obvious.

(3) ⇒ (4): Given $c \in C_s$, take fibers over $\{s\} \in \underline{s}$ and note that
$$\underline{\mathrm{Fun}}_{/C_{\underline{s}},S^{s/}}(\underline{c}, X_{\underline{s}})_s \simeq \mathrm{Fun}_{/C_c}(\{c\}, X_s) \simeq X_c.$$

(4) ⇒ (1): We must check that F_s is an equivalence for all $s \in S$, for which it suffices to check fiberwise over C_s by the hypothesis. □

11.7. **Lemma.** *Let $\overline{q} : S \star_S K \longrightarrow \underline{\mathbf{Spc}}_S$ be a S-functor which extends $q : K \longrightarrow \underline{\mathbf{Spc}}_S$. Let $\overline{X} \longrightarrow S \star_S K$ be a left fibration which is an unstraightening of $\overline{q}^\dagger$, and let $X = \overline{X} \times_{S \star_S K} K$. Then $\overline{q}$ is a S-limit diagram if and only if the restriction S-functor*
$$R : \underline{\mathrm{Map}}_{/S \star_S K,S}(S \star_S K, \overline{X}) \longrightarrow \underline{\mathrm{Map}}_{/S \star_S K,S}(K, \overline{X}) \cong \underline{\mathrm{Map}}_{/K,S}(K, X)$$
is an equivalence.

Proof. In view of [10, Corollary 3.3.3.4], R_s is a map from the limit of $\overline{q}^\dagger|_{\underline{s} \star_{\underline{s}} K_{\underline{s}}}$ to the limit of $q^\dagger|_{K_{\underline{s}}}$ induced by precomposition on the diagram. But by Proposition 5.6, $\overline{q}$ is a S-limit diagram if and only if $\overline{q}^\dagger$ is a right Kan extension of $q^\dagger$, in which case both of the limits in question are equivalent to $\overline{q}^\dagger(s)$. The assertion now follows. □

[19] $\underline{\mathrm{Map}}$ refers here to the maximal sub-left fibration of $\underline{\mathrm{Fun}}$ and not the S-mapping space functor.

11.8. **Proposition.** *Let $\overline{p} : S \star_S K \longrightarrow C$ be a S-functor. The following are equivalent:*

(1) *$\overline{p}$ is a S-limit diagram.*
(2) *For all $s \in S$ and $c \in C_s$,*

$$\underline{\mathrm{Map}}_{C_{\underline{s}}}(c, \overline{p}_{\underline{s}}(-)) : \underline{s} \star_{\underline{s}} K_{\underline{s}} \longrightarrow \underline{\mathbf{Spc}}_{S^{s/}}$$

is a $S^{s/}$-limit diagram.
(3) *For all $s \in S$ and $c \in C_s$,*

$$\underline{\mathrm{Map}}_{/C_{\underline{s}}, S^{s/}}(\underline{c}, C_{\underline{s}}^{/(\overline{p}_{\underline{s}}, S^{s/})}) \longrightarrow \underline{\mathrm{Map}}_{/C_{\underline{s}}, S^{s/}}(\underline{c}, C_{\underline{s}}^{/(p_{\underline{s}}, S^{s/})})$$

is an equivalence.

Moreover, if the above conditions obtain, then

$$\underline{\mathrm{Map}}_{/C_{\underline{s}}, S^{s/}}(\underline{c}, C_{\underline{s}}^{/(p_{\underline{s}}, S^{s/})}) \simeq \underline{\mathrm{Map}}_{C_{\underline{s}}}(c, \overline{p}_{\underline{s}}(v))$$

where v is the cone point $\{s\} \in \underline{s} \star_{\underline{s}} K_{\underline{s}}$.

Proof. (2) $\Leftrightarrow$ (3): We will show that the statements match after fixing $c \in C_s$. To ease notation, let us replace $S^{s/}$ by S and suppose that $s \in S$ is an initial object. By Lemma 11.7 and using that $C^{\underline{c}/}$ is the S-unstraightening of $\underline{\mathrm{Map}}_C(c, -)$, $\underline{\mathrm{Map}}_C(c, \overline{p}(-))$ is a S-limit diagram if and only if

$$\underline{\mathrm{Map}}_{/C,S}(S \star_S K, C^{\underline{c}/}) \longrightarrow \underline{\mathrm{Map}}_{/C,S}(K, C^{\underline{c}/})$$

is an equivalence. By Corollary 4.27, this map is equivalent by a zig-zag to the map

$$\underline{\mathrm{Map}}_{/C,S}(\underline{c}, C^{/(\overline{p},S)}) \longrightarrow \underline{\mathrm{Map}}_{/C,S}(\underline{c}, C^{/(p,S)}).$$

The assertion now follows. The last assertion also follows in view of the equivalence $C^{/(\overline{p},S)} \simeq C^{/\underline{\overline{p}(v)}}$ and $\underline{\mathrm{Map}}_{/C,S}(\underline{c}, C^{/\underline{\overline{p}(v)}}) \simeq \underline{c} \times_C C^{/\underline{\overline{p}(v)}} \simeq \underline{\mathrm{Map}}_C(c, \overline{p}(v))$.

(1) $\Leftrightarrow$ (3): This follows from Lemma 11.6 applied to $C^{/(\overline{p},S)} \longrightarrow C^{/(p,S)}$, which is a map of S-right fibrations over C. □

11.9. **Corollary.** *Let $F : C \longrightarrow D$ be a S-functor. Then*

(1) *F strongly preserves S-limits if and only if for all $s \in S$ and $d \in D_s$,*

$$\underline{\mathrm{Map}}_{D_{\underline{s}}}(d, F_{\underline{s}}(-)) : C_{\underline{s}} \longrightarrow \underline{\mathbf{Spc}}_{S^{s/}}$$

preserves $S^{s/}$-limits.
(2) *F strongly preserves S-colimits if and only if for all $s \in S$ and $d \in D_s$,*

$$\underline{\mathrm{Map}}_{D_{\underline{s}}}(F_{\underline{s}}(-), d) = \underline{\mathrm{Map}}_{D_{\underline{s}}^{vop}}(d, F_{\underline{s}}^{vop}(-)) : C_{\underline{s}}^{vop} \longrightarrow \underline{\mathbf{Spc}}_{S^{s/}}$$

preserves $S^{s/}$-limits.

11.10. **Corollary.** *Let C be a S-category. The Yoneda embedding $j : C \longrightarrow \mathbf{P}_S(C)$ strongly preserves and detects S-limits.*

Proof. Combine Proposition 11.8 and Proposition 9.17. □

Proof of Theorem 11.5. By Theorem 10.5, we have a S-adjunction

$$j_! : \underline{\mathrm{Fun}}_S(C, E) \rightleftarrows \underline{\mathrm{Fun}}_S(\mathbf{P}_S(C), E) : j^*$$

with $j^* j_! \simeq \mathrm{id}$ and the essential image of $j_!$ spanned by the left $S^{s/}$-Kan extensions ranging over all $s \in S$. By Proposition 8.4, taking cocartesian sections yields an adjunction

$$j_! : \mathrm{Fun}_S(C, E) \rightleftarrows \mathrm{Fun}_S(\mathbf{P}_S(C), E) : j^*$$

again with $j^* j_! \simeq \mathrm{id}$ and the essential image of $j_!$ spanned by the left S-Kan extensions. Both assertions will therefore follow if we prove that for a S-functor $F : \mathbf{P}_S(C) \longrightarrow E$, F strongly preserves S-colimits if and only if F is a left S-Kan extension of its restriction $f = F|_C$.

For the 'only if' direction, because $\mathrm{id}_{\mathbf{P}_S(C)}$ is a S-left Kan extension of j by the S-Yoneda lemma 11.1, $F = F \circ \mathrm{id}_{\mathbf{P}_S(C)}$ is a left S-Kan extension as it is the postcomposition of $\mathrm{id}_{\mathbf{P}_S(C)}$ with a strongly S-colimit preserving functor.

For the 'if' direction, we use the criterion of Corollary 11.9. Replacing $S^{s/}$ by S and supposing that $s \in S$ is an initial object, we reduce to showing that for all $x \in E_s$, $\underline{\mathrm{Map}}_E(F(-), x) : \mathbf{P}_S(C)^{vop} \longrightarrow \underline{\mathbf{Spc}}_S$ preserves S-limits. We first observe that F^{vop} is a S-right Kan extension (of f^{vop}), hence so is $\underline{\mathrm{Map}}_E(F(-), x) = \underline{\mathrm{Map}}_{E^{vop}}(x, -) \circ F^{vop}$ as the postcomposition of a S-right Kan extension with a strongly S-limit preserving functor. However, by the vertical opposite of the S-Yoneda lemma, for any S-functor $G : C^{vop} \longrightarrow \underline{\mathbf{Spc}}_S$, the strongly S-limit preserving S-functor $\underline{\mathrm{Map}}_{\mathbf{P}_S(C)}(-, G)$ is a S-right Kan extension of G. Applying this for $G = \underline{\mathrm{Map}}_E(f(-), x)$, we conclude. □

12. Bousfield–Kan formula

In this section, we prove two decomposition formulas for S-colimits which resemble the classical Bousfield–Kan formula for computing homotopy colimits. We first study the situation when $S = \Delta^0$.

12.1. **Notation.** Let K be a simplicial set and let $\Delta_{/K}$ be the nerve of the category of simplices of K. We denote the first vertex map by $\upsilon_K : \Delta^{op}_{/K} \longrightarrow K$ and the last vertex map by $\mu_K : \Delta_{/K} \longrightarrow K$.

By [10, Proposition 4.2.3.14], μ_K is final. Unfortunately, this is the wrong direction for the purposes of obtaining a Bousfield–Kan type formula, since $\Delta_{/K}$ is a *cartesian* fibration over Δ. To rectify this state of affairs, we prove that υ_K is in fact final.

12.2. **Proposition.** *Let K be a simplicial set. Then the first vertex map $\upsilon_K : \Delta^{op}_{/K} \longrightarrow K$ is final. Equivalently, the last vertex map $\mu_{K^{op}}$ is initial.*

Proof. Note that υ_K is natural in K and that $\Delta^{op}_{/(-)} : s\mathbf{Set} \longrightarrow s\mathbf{Set}$ preserves colimits. Recall from [10, Proposition 4.1.2.5] that a map $f : X \longrightarrow Y$ is final if and only if it is a contravariant equivalence in $s\mathbf{Set}_{/Y}$. It follows that the class of final maps is stable under filtered colimits, so we may suppose that K has finitely many nondegenerate simplices. Using left properness of the contravariant model structure, by induction we reduce to the assertion for $K = \Delta^n$. But in this case υ_K is final by the proof of [10, Variant 4.2.3.15] (which proves the result when K is the nerve of a category).

For the second assertion, we note that the reversal isomorphism $\Delta_{/K^{op}} \cong \Delta_{/K}$ interchanges $\mu_{K^{op}}$ and $(\upsilon_K)^{op}$. □

12.3. **Corollary** (Bousfield–Kan formula)**.** *Suppose that C admits (finite) coproducts. Then for a (finite) simplicial set K and a map $p : K \longrightarrow C$, the colimit of p exists if and only if the geometric realization*

$$\left| \coprod_{x \in K_0} p(x) \Longleftarrow \coprod_{\alpha \in K_1} p(\alpha(0)) \Lleftarrow \coprod_{\sigma \in K_2} p(\sigma(0)) \ \dots \right|$$

exists, in which case the colimit of p is computed by the geometric realization.

Proof. The fibers of the cocartesian fibration $\pi_K : \Delta^{op}_{/K} \longrightarrow \Delta^{op}$ are the discrete sets K_n. Therefore, the left Kan extension of $p \circ \upsilon_K$ along π_K exists. By Proposition 12.2, $\operatorname{colim} p \simeq \operatorname{colim} p \circ \upsilon_K$, and the latter is computed as the colimit of $(\pi_K)_!(p \circ \upsilon_K)$ by the transitivity of left Kan extensions. □

We also have a variant of Cor 12.3 where the coproducts over K_n are replaced by colimits indexed by the spaces $\mathrm{Map}(\Delta^n, K)$. To formulate this, we need to introduce some auxiliary constructions. Let $\xi : W \longrightarrow \Delta^{op}$ be the opposite of the relative nerve of the inclusion $\Delta \longrightarrow s\mathbf{Set}$; this is a cartesian fibration which is an explicit model for the tautological cartesian fibration over Δ^{op} pulled back from the universal cartesian fibration over $\mathbf{Cat}^{op}_\infty$. Let $\lambda : \Delta^{op} \longrightarrow W$ be the 'first vertex' section of ξ which sends an n-simplex $\Delta^{a_0} \leftarrow ... \leftarrow \Delta^{a_n}$ to the n-simplex

$$\begin{array}{ccccccc}
\Delta^n & \longleftarrow & \dots & \longleftarrow & \Delta^{\{n-1,n\}} & \longleftarrow & \Delta^{\{n\}} \\
\downarrow{\scriptstyle (\lambda a)_0} & & & & \downarrow{\scriptstyle (\lambda a)_{n-1}} & & \downarrow{\scriptstyle (\lambda a)_n} \\
\Delta^{a_0} & \longleftarrow & \dots & \longleftarrow & \Delta^{a_{n-1}} & \longleftarrow & \Delta^{a_n}
\end{array}$$

of W specified by $(\lambda a)_i(0) = 0$ for all $0 \leq i \leq n$.

For an ∞-category C, let $Z_C = \widetilde{\mathrm{Fun}}_{\Delta^{op}}(W, C \times \Delta^{op})$ and let $Z'_C \subset Z_C$ be the sub-simplicial set on the simplices σ such that every edge of σ is cocartesian (with respect to the structure map to Δ^{op}), so that $Z'_C \longrightarrow \Delta^{op}$ is the maximal sub-left fibration in $Z_C \longrightarrow \Delta^{op}$. Define a Δ^{op}-functor $\Delta^{op}_{/C} \longrightarrow Z_C$ as adjoint to the map $\Delta^{op}_C \times_{\Delta^{op}} W \longrightarrow C$ which sends an n-simplex

$$\begin{array}{ccccccc}
\Delta^n & \longleftarrow & \dots & \longleftarrow & \Delta^{\{n-1,n\}} & \longleftarrow & \Delta^{\{n\}} \\
\downarrow{\scriptstyle (\lambda a)_0} & & & & \downarrow{\scriptstyle (\lambda a)_{n-1}} & & \downarrow{\scriptstyle (\lambda a)_n} \\
\Delta^{a_0} & \longleftarrow & \dots & \longleftarrow & \Delta^{a_{n-1}} & \longleftarrow & \Delta^{a_n} \\
\downarrow{\scriptstyle \tau} & \swarrow & & \swarrow & & & \\
C & & & & & &
\end{array}$$

to $\tau \circ (\lambda a)_0 \in C_n$. Note that since $\Delta^{op}_{/C} \longrightarrow \Delta^{op}$ is a left fibration, this functor factors through Z'_C.

Define a 'first vertex' functor $\Upsilon_C : Z_C \longrightarrow C$ by precomposition with ι (using the isomorphism $\widetilde{\mathrm{Fun}}_{\Delta^{op}}(\Delta^{op}, C \times \Delta^{op}) \cong C \times \Delta^{op}$). We then have a factorization of the first vertex map as

$$\Delta^{op}_{/C} \longrightarrow Z'_C \longrightarrow Z_C \xrightarrow{\Upsilon_C} C.$$

12.4. **Proposition.** *The functors Υ_C and $\Upsilon'_C = (\Upsilon_C)|_{Z'_C}$ are final.*

Proof. We first prove that Υ_C is final by verifying the hypotheses of [10, Theorem 4.1.3.1]. Let $c \in C$. The map $Z_C \longrightarrow C$ is functorial in C, so we have a map $Z_{C_{c/}} \longrightarrow Z_C \times_C C_{c/}$. We claim that this map is a trivial Kan fibration. Unwinding the definitions, this amounts to showing that for every cofibration $A \longrightarrow B$ of simplicial sets over Δ^{op}, we can solve the lifting problem

$$\begin{array}{ccc}
B \cup_A A \times_{\Delta^{op}} W & \longrightarrow & C_{c/} \\
\downarrow & \nearrow & \downarrow \\
B \times_{\Delta^{op}} W & \longrightarrow & C.
\end{array}$$

Since the class of left anodyne morphisms is right cancellative, we may suppose $A = \varnothing$. It thus suffices to prove that $\lambda_B = B \times_{\Delta^{op}} \lambda : B \longrightarrow B \times_{\Delta^{op}} W$ is left anodyne for any map of simplicial sets $B \longrightarrow \Delta^{op}$. Observe that even though λ is not a cartesian section, it is a left adjoint relative to Δ^{op} to ξ by [12, Proposition 7.3.2.6] and the uniqueness of adjoints, since on the fibers it restricts to the adjunction $\{0\} \rightleftarrows \Delta^n$. Consequently, for any ∞-category B and functor $B \longrightarrow \Delta^{op}$, by [12, Proposition 7.3.2.5] λ_B is a left adjoint, hence left anodyne. From this, we deduce the general case by using the characterization in [10, Proposition 4.1.2.1] of the left anodyne maps $X \longrightarrow Y$ as the trivial cofibrations in $s\mathbf{Set}_{/Y}$ equipped with the covariant model structure. Indeed, arguing as in the proof of Proposition 12.2, by induction on the nondegenerate simplices of B we reduce to the known case $B = \Delta^n$.

We next prove that Z_C is weakly contractible if C is, which will conclude the proof for Υ_C. For this, another application of (the opposite of) [12, Proposition 7.3.2.6] shows that the Δ^{op}-functor $C \times \Delta^{op} \longrightarrow Z_C$ defined by precomposition by ξ is a left adjoint relative to Δ^{op} to the functor $(\Upsilon_C, \mathrm{id}_{\Delta^{op}})$, because it restricts to the adjunction $\iota\colon C \rightleftarrows \mathrm{Fun}(\Delta^n, C) :\mathrm{ev}_0$ on the fibers. Hence, $|Z_C| \simeq |C \times \Delta^{op}| \simeq |C|$, and the latter is contractible by hypothesis.

We employ the same strategy to show that Υ'_C is final. Since $C_{c/} \longrightarrow C$ is conservative, the trivial Kan fibration above restricts to yield a trivial Kan fibration $Z'_{C_{c/}} \longrightarrow Z'_C \times_C C_{c/}$. Thus it suffices to show that Z'_C is weakly contractible if C is. By (the opposite of) [6, Proposition 7.3], the cocartesian fibration $Z'_C \longrightarrow \Delta^{op}$ is classified by the functor

$$\Delta^{op} \xrightarrow{i^{op}} \mathbf{Cat}_\infty \xrightarrow{\mathrm{Map}(-,C)} \mathbf{Spc}.$$

Let R denote the right adjoint to the colimit-preserving functor $L : \mathrm{Fun}(\Delta^{op}, \mathbf{Spc}) \longrightarrow \mathbf{Cat}_\infty$ left Kan extended from the inclusion $i : \Delta \subset \mathbf{Cat}_\infty$; R sends an ∞-category to its corresponding complete

Segal space. Then $R(C) \simeq \mathrm{Map}(-, C) \circ i^{op}$. For any $X_\bullet \in \mathrm{Fun}(\Delta^{op}, \mathbf{Spc})$, we have $\operatorname{colim} X \simeq |L(X_\bullet)|$, hence

$$\operatorname{colim} R(C) \simeq |(L \circ R)(C)| \simeq |C|,$$

where $L \circ R \simeq \mathrm{id}$ by [11, Corollary 4.3.16]. By [10, Corollary 3.3.4.6], $|Z'_C| \simeq \operatorname{colim} R(C)$, so we conclude that $|Z'_C|$ is contractible. $\square$

The following corollary was previously proven by Mazel-Gee in [15].

12.5. **Corollary** (Bousfield–Kan formula, 'simplicial' variant)**.** *Suppose that C admits colimits indexed by spaces. Then for any ∞-category K and functor $p : K \longrightarrow C$, the colimit of p exists if and only if the geometric realization*

$$\left| \operatorname*{colim}_{x \in \mathrm{Map}(\Delta^0, K)} p(x) \leftleftarrows \operatorname*{colim}_{\alpha \in \mathrm{Map}(\Delta^1, K)} p(\alpha(0)) \,\substack{\longleftarrow\\\longleftarrow\\\longleftarrow}\, \operatorname*{colim}_{\sigma \in \mathrm{Map}(\Delta^2, K)} p(\sigma(0)) \;\cdots \right|$$

exists, in which case the colimit of p is computed by the geometric realization.

Proof. Using Proposition 12.4, we may repeat the proof of Corollary 12.3, now using the span

$$\Delta^{op} \leftarrow Z'_K \xrightarrow{\Upsilon'_K} K.$$

$\square$

We now proceed to relativize the above picture, starting with the map Υ_C. Let $C \longrightarrow S$ be a S-category. Define the map

$$\Upsilon_{C,S} : \widetilde{\mathrm{Fun}}_{\Delta^{op} \times S/S}(W \times S, \Delta^{op} \times C) \longrightarrow C$$

to be the composition of the map to $\widetilde{\mathrm{Fun}}_{\Delta^{op} \times S/S}(\Delta^{op} \times S, \Delta^{op} \times C)$ given by precomposition by $\lambda \times \mathrm{id}_S$, together with the equivalence of Lemma 9.5 of this to $\Delta^{op} \times C$ and the projection to C. Define $\Upsilon'_{C,S}$ to be the restriction of $\Upsilon_{C,S}$ to the maximal sub-left fibration (with respect to $\Delta^{op} \times S$).

12.6. **Theorem.** *The S-functors $\Upsilon_{C,S}$ and $\Upsilon'_{C,S}$ are S-final.*

Proof. For every object $s \in S$, we have a commutative diagram

$$\begin{array}{ccccc}
\widetilde{\mathrm{Fun}}_{\Delta^{op} \times S/S}(W \times S, \Delta^{op} \times C)_s & \xrightarrow{(\lambda \times \mathrm{id}_S)^*_s} & \widetilde{\mathrm{Fun}}_{\Delta^{op} \times S/S}(\Delta^{op} \times S, \Delta^{op} \times C)_s & \longrightarrow & C_s \\
\downarrow \simeq & & \downarrow \simeq & & \downarrow = \\
\widetilde{\mathrm{Fun}}_{\Delta^{op}}(W, \Delta^{op} \times C_s) & \xrightarrow{\lambda^*} & \widetilde{\mathrm{Fun}}_{\Delta^{op}}(\Delta^{op}, \Delta^{op} \times C_s) \cong \Delta^{op} \times C_s & \xrightarrow{\mathrm{pr}_{C_s}} & C_s
\end{array}$$

where the left two vertical maps are given by the natural categorical equivalences of Lemma 9.6; the only point to note is that the equivalences of Lemma 9.5 and Lemma 9.6 coincide when the first variable is trivial. By Proposition 12.4, Υ_{C_s} is final, so $(\Upsilon_{C,S})_s$ is final. By the S-cofinality Theorem 6.7, $\Upsilon_{C,S}$ is S-final. A similar argument shows that $\Upsilon'_{C,S}$ is S-final. $\square$

The process of relativizing υ_C is considerably more involved. We begin with some preliminaries on the relative nerve construction. Let J be a category.

12.7. **Lemma.** *The adjunctions*

$$\mathfrak{F}_J : s\mathbf{Set}_{/N(J)} \rightleftarrows \mathrm{Fun}(J, s\mathbf{Set}) : N_J$$
$$\mathfrak{F}^+_J : s\mathbf{Set}^+_{/N(J)} \rightleftarrows \mathrm{Fun}(J, s\mathbf{Set}^+) : N^+_J$$

of [10, §3.2.5] *are simplicial.*

Proof. Let $\underline{K} : J \longrightarrow s\mathbf{Set}$ denote the constant functor at a simplical set K. We have an obvious map $\chi_K : N(J) \times K \longrightarrow N_J(\underline{K})$ natural in K and hence a map

$$(\eta_X, \chi_K \circ \mathrm{pr}) : X \times K \longrightarrow N_J(\mathfrak{F}_J X \times \underline{K}) \cong N_J \mathfrak{F}_J X \times N_J(\underline{K})$$

natural in X and K. We want to show the adjoint

$$\theta_{X,K} : \mathfrak{F}_J(X \times K) \longrightarrow \mathfrak{F}_J(X) \times \underline{K}$$

is an isomorphism. Both sides preserve colimits separately in each variable, so we may suppose $X = \Delta^n \longrightarrow J$ and $K = \Delta^m$. By [10, Example 3.2.5.6], $\mathfrak{F}_I(I)(-) \cong N(I_{/-})$, and by [10, Remark 3.2.5.8], for any functor $f : I \longrightarrow J$, the square

$$\begin{array}{ccc} s\mathbf{Set}_{/N(I)} & \xrightarrow{f_!} & s\mathbf{Set}_{/N(J)} \\ \downarrow{\scriptstyle \mathfrak{F}_I} & & \downarrow{\scriptstyle \mathfrak{F}_J} \\ \mathrm{Fun}(I, s\mathbf{Set}) & \xrightarrow{f_!} & \mathrm{Fun}(J, s\mathbf{Set}) \end{array}$$

commutes. Letting $I = \Delta^n \times \Delta^m$ and $f : I \longrightarrow J$ be the structure map, we have

$$\mathfrak{F}_I(\Delta^n \times \Delta^m)(k,l) \cong (\Delta^n)_{/k} \times (\Delta^m)_{/l} \cong \Delta^k \times \Delta^l.$$

Factoring f as $\Delta^n \times \Delta^m \xrightarrow{g} \Delta^n \xrightarrow{h} J$, we then have

$$g_! \mathfrak{F}_I(\Delta^n \times \Delta^m)(k) \cong \Delta^i \times \Delta^m.$$

Let $G = g_! \mathfrak{F}_I(\Delta^n \times \Delta^m)$, so that $\mathfrak{F}_J(\Delta^n \times \Delta^m)(j) \cong (h_! G)(j)$. Then

$$(h_! G)(j) \cong \operatorname*{colim}_{\Delta^n \times_J J_{/j}} \left((k, h(k) \to j) \mapsto \Delta^k\right) \times \Delta^m \cong \mathfrak{F}_J(\Delta^n)(j) \times \Delta^m$$

and one can verify that $\theta_{X,K}$ implements this isomorphism. For the assertion about $\mathfrak{F}^+_J \dashv N^+_J$, recall that the simplicial tensor $s\mathbf{Set} \times s\mathbf{Set}^+ \longrightarrow s\mathbf{Set}^+$ is given by $(K, X) \mapsto K^\sharp \times X$. Consequently, in the above argument we may simply replace Δ^m by $(\Delta^m)^\sharp$ to conclude. □

Since $N^+_J(\underline{S^\sharp}) = N(J) \times S^\sharp$, the adjunction $\mathfrak{F}^+_J \dashv N^+_J$ lifts to an adjunction

$$\mathfrak{F}^+_{J,S} \colon s\mathbf{Set}^+_{/N(J)\times S} \rightleftarrows \mathrm{Fun}(J, s\mathbf{Set}^+_{/S}) : N^+_{J,S}$$

between the overcategories. Moreover, for any functor $f : T \longrightarrow S$, the square

$$\begin{array}{ccc} \mathrm{Fun}(J, s\mathbf{Set}^+_{/S}) & \xrightarrow{N^+_{J,S}} & s\mathbf{Set}^+_{/N(J)\times S} \\ \downarrow{\scriptstyle f^*} & & \downarrow{\scriptstyle (\mathrm{id}\times f)^*} \\ \mathrm{Fun}(J, s\mathbf{Set}^+_{/T}) & \xrightarrow{N^+_{J,T}} & s\mathbf{Set}^+_{/N(J)\times T}, \end{array}$$

commutes.

12.8. **Proposition.** *Equip* $s\mathbf{Set}^+_{/N(J)\times S}$ *with the cocartesian model structure and* $\mathrm{Fun}(J, s\mathbf{Set}^+_{/S})$ *with the projective model structure, where* $s\mathbf{Set}^+_{/S}$ *has the cocartesian model structure. Then the adjunction*

$$\mathfrak{F}^+_{J,S} \colon s\mathbf{Set}^+_{/N(J)\times S} \rightleftarrows \mathrm{Fun}(J, s\mathbf{Set}^+_{/S}) : N^+_{J,S}$$

is a Quillen equivalence.

Proof. We first prove that the adjunction is Quillen. Because this is a simplicial adjunction between left proper simplicial model categories, it suffices to show that $\mathfrak{F}^+_{J,S}$ preserves cofibrations and $N^+_{J,S}$ preserves fibrant objects. Observe that the slice model structure on

$$s\mathbf{Set}^+_{/N(J)\times S} \cong (s\mathbf{Set}^+_{/N(J)})_{/(N(J)\times S)^\sharp}$$

is a localization of the cocartesian model structure. Similarly, the slice model structure on

$$\mathrm{Fun}(J, s\mathbf{Set}^+_{/S}) \cong \mathrm{Fun}(J, s\mathbf{Set}^+)_{/\underline{S^\sharp}}$$

is a localization of the projective model structure, since the trivial fibrations for the two model structures coincide and postcomposition by $\pi_! : s\mathbf{Set}^+_{/S} \longrightarrow s\mathbf{Set}^+$ gives a Quillen left adjoint between the projective model structures. Since the lift of a Quillen adjunction $L\colon M \rightleftarrows N : R$ to the adjunction $\widetilde{L}\colon M_{/R(x)} \rightleftarrows N_{/x} : \widetilde{R}$ is Quillen for the slice model structures, we deduce that $\mathfrak{F}^+_{J,S}$ preserves cofibrations.

Now suppose $F : J \longrightarrow s\mathbf{Set}^+_{/S}$ is fibrant. Since S is an ∞-category, $F \to \underline{S}$ is a fibration in $\mathrm{Fun}(J, s\mathbf{Set})$. Hence $N_{J,S}(F) \longrightarrow N(J) \times S$ is a categorical fibration. We verify that it is a cocartesian fibration (with every marked edge cocartesian) by solving the lifting problem ($n \geq 1$)

$$\begin{array}{ccc} {}_\natural\Lambda^n_0 & \longrightarrow & N^+_{J,S}(F) \\ \big\downarrow & \nearrow & \big\downarrow \\ {}_\natural\Delta^n & \xrightarrow[(j_\bullet, s_\bullet)]{} & (N(J) \times S)^\sharp. \end{array}$$

Unwinding the definitions, this amounts to solving the lifting problem

$$\begin{array}{ccc} {}_\natural\Lambda^n_0 & \longrightarrow & F(j_n) \\ \big\downarrow & \nearrow & \big\downarrow \\ {}_\natural\Delta^n & \xrightarrow[s_\bullet]{} & S^\sharp, \end{array}$$

and the dotted lift exists because $F(j_n)$ is cocartesian over S with the cocartesian edges marked. Finally, it is easy to see that marked edges compose and are stable under equivalence. We conclude that $N^+_{J,S}(F)$ is fibrant in $s\mathbf{Set}^+_{/N(J)\times S}$.

To prove that the Quillen adjunction is a Quillen equivalence, we will show that the induced adjunction of ∞-categories

$$\mathfrak{F}'^+_{J,S}\colon N((s\mathbf{Set}^+_{/N(J)\times S})^\circ) \rightleftarrows N(\mathrm{Fun}(J, s\mathbf{Set}^+_{/S})^\circ) : N'^+_{J,S}$$

is an adjoint equivalence, where $N'^+_{J,S}$ is the simplicial nerve of $N^+_{J,S}$ and $\mathfrak{F}'^+_{J,S}$ is any left adjoint to $N'^+_{J,S}$. We first check that $N'^+_{J,S}$ is conservative. Indeed, for this we may work in the model category: for a natural transformation $\alpha : F \to G$ in $\mathrm{Fun}(J, s\mathbf{Set}^+_{/S})$, $N^+_{J,S}(F) \longrightarrow N^+_{J,S}(G)$ on fibers is given by $F(j)_s \longrightarrow G(j)_s$, hence if F, G are fibrant and $N^+_{J,S}(\alpha)$ is an equivalence then α is as well. It now suffices to show that the unit transformation $\eta : \mathrm{id} \longrightarrow N'^+_{J,S}\mathfrak{F}'^+_{J,S}$ is an equivalence. We have the known equivalence $N((s\mathbf{Set}^+_{/N(J)\times S})^\circ) \simeq \mathrm{Fun}(N(J) \times S, \mathbf{Cat}_\infty)$ so it further suffices to check that the map

$$(\mathrm{id} \times i_s)^* \longrightarrow (\mathrm{id} \times i_s)^* N'^+_{J,S}\mathfrak{F}'^+_{J,S} \simeq N'^+_J i_s^* \mathfrak{F}'^+_{J,S}$$

is an equivalence for all $s \in S$, $i_s : \{s\} \longrightarrow S$ the inclusion. Equivalently, since $\mathfrak{F}^+_J \dashv N^+_J$ is a Quillen equivalence by [10, Proposition 3.2.5.18], we must show that the adjoint map

$$\mathfrak{F}'^+_J i_s^* \longrightarrow (\mathrm{id} \times i_s)^* \mathfrak{F}'^+_{J,S}$$

is an equivalence. This statement is in turn equivalent to the adjoint map

$$\theta : N'^+_{J,S}(i_s)_* \longrightarrow (\mathrm{id} \times i_s)_* N'^+_J$$

being an equivalence. Recall that for a functor $f : T \longrightarrow S$, $f_* : \mathrm{Fun}(T, \mathbf{Cat}_\infty) \longrightarrow \mathrm{Fun}(S, \mathbf{Cat}_\infty)$ is induced by $\pi_* \rho^* : s\mathbf{Set}^+_{/T} \longrightarrow s\mathbf{Set}^+_{/S}$ for the span

$$S^\sharp \xleftarrow{\pi} (\mathcal{O}(S) \times_S T)^\sharp \xrightarrow{\rho} T^\sharp$$

with π given by evaluation at 0 and ρ projection to T. Moreover, for a functor $\mathrm{id} \times f : U \times T \longrightarrow U \times S$, we may elect to use the span

$$(U \times S)^\sharp \xleftarrow{\mathrm{id}\times\pi} (U \times \mathcal{O}(S) \times_S T)^\sharp \xrightarrow{\mathrm{id}\times\rho} (U \times T)^\sharp$$

to model $(\mathrm{id} \times f)_*$. Letting $f = i_s$, we see that θ is induced by the map

$$N^+_{J,S}\pi_*\rho^* \longrightarrow (\mathrm{id} \times \pi)_* N^+_{J,S^{s/}}\rho^* \cong (\mathrm{id} \times \pi)_*(\mathrm{id} \times \rho)^* N^+_J.$$

where the first map is adjoint to the isomorphism $(\mathrm{id}\times\pi)^* N^+_{J,S} \cong N^+_{J,S^{s/}}\pi^*$. Direct computation reveals that this map is an equivalence on fibrant $F : J \longrightarrow s\mathbf{Set}^+$. □

We now return to the situation of interest. Let C be a S-category with structure map $\pi : C \longrightarrow S$. We first extend our existing notation $\underline{x}$ for objects $x \in C$.

12.9. **Notation.** For an n-simplex σ of C, define

$$\underline{\sigma} = \{\sigma\} \times_{\mathrm{Fun}(\Delta^n\times\{0\},C)} \mathrm{Fun}((\Delta^n)^\flat \times (\Delta^1)^\sharp, {}_\natural C) \times_{\mathrm{Fun}(\Delta^n\times\{1\},S)} S.$$

12.10. **Lemma.** *There exists a map $b_\sigma : \underline{\sigma} \longrightarrow \{\pi\sigma(n)\} \times_S \mathcal{O}(S) = S^{\pi\sigma(n)/}$ which is a trivial Kan fibration.*

Proof. First define a map $b'_\sigma : \underline{\sigma} \longrightarrow \underline{\pi\sigma}$ to be the pullback of the map

$$(e_0, \mathcal{O}(\pi))_* : \mathrm{Fun}(\Delta^n, \mathcal{O}^{cocart}(C)) \longrightarrow C^{\Delta^n} \times_{S^{\Delta^n}} \mathrm{Fun}(\Delta^n, \mathcal{O}(S))$$

over $\{\sigma\}$ and S. Since $(e_0, \mathcal{O}(\pi))$ is a trivial Kan fibration, so is b'_σ. Next, let K be the pushout $\Delta^n \times \{0\} \cup_{\{n\}\times\{0\}} \{n\} \times \Delta^1$. We claim that the map $\mathrm{Fun}(\Delta^n, \mathcal{O}(S)) \times_{S^{\Delta^n}} S \longrightarrow \mathrm{Fun}(K, S)$ induced by $K \subset \Delta^n \times \Delta^1$ is a trivial Kan fibration. For a monomorphism $A \longrightarrow B$, we need to solve the lifting problem

$$\begin{array}{ccc} A & \longrightarrow & \mathrm{Fun}(\Delta^n, \mathcal{O}(S)) \times_{S^{\Delta^n}} S \\ \downarrow & \nearrow & \downarrow \\ B & \longrightarrow & \mathrm{Fun}(K, S). \end{array}$$

This transposes to

$$\begin{array}{ccc} A \times \Delta^n \bigcup_{A\times\{n\}} B \times \{n\} & \longrightarrow & \mathcal{O}(S) \\ \downarrow & \nearrow & \downarrow \mathrm{ev}_0 \\ B \times \Delta^n & \longrightarrow & S \end{array}$$

and the lefthand map is right anodyne by [10, Corollary 2.1.2.7], hence the dotted lift exists as ev_0 is a cartesian fibration. Now define b''_σ to be the pullback

$$\underline{\pi\sigma} = \{\pi\sigma\} \times_{S^{\Delta^n}} \mathrm{Fun}(\Delta^n, \mathcal{O}(S)) \times_{S^{\Delta^n}} S \longrightarrow \{\pi\sigma\} \times_{S^{\Delta^n}} \mathrm{Fun}(K, S) \cong S^{\pi\sigma(n)/};$$

this is also a trivial Kan fibration. Finally, let $b_\sigma = b''_\sigma \circ b'_\sigma$. □

We will regard $\underline{\sigma}$ as a $S^{\pi\sigma(n)/}$ or S-category via b_σ. We also have a target map $\underline{\sigma} \longrightarrow C^{\Delta^n}$ induced by $\Delta^n \times \{1\} \subset \Delta^n \times \Delta^1$. This covers the target map $S^{\pi\sigma(n)/} \longrightarrow S$ and is a S-functor.

Define a functor $F_C : \Delta^{op} \longrightarrow s\mathbf{Set}^+_{/S}$ on objects $[n]$ by

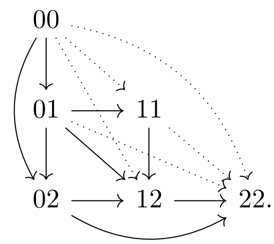
$$F_C([n]) = \bigsqcup_{\sigma\in C_n} \underline{\sigma}^\sharp$$

and on morphisms $\alpha : [m] \to [n]$ by the map $\underline{\sigma} \longrightarrow \underline{\sigma\alpha}$ induced by precomposition by $\alpha : \Delta^m \longrightarrow \Delta^n$.

12.11. **Remark.** The map $\underline{\sigma} \longrightarrow \underline{\sigma(n)}$ is compatible with the maps b_σ and $b_{\sigma(n)}$ of Lemma 12.10, hence is a categorical equivalence (in fact, a trivial Kan fibration). Consequently, given a morphism $f : x \to y$ in C, by choosing an inverse to $\underline{f} \xrightarrow{\simeq} \underline{y}$ we obtain a map $f^* : \underline{y} \longrightarrow \underline{x}$, unique up to contractible choice. Moreover, if f lies over an equivalence, then $\underline{f} \longrightarrow \underline{x}$ is a trivial Kan fibration, so we also obtain a map $f_! : \underline{x} \longrightarrow \underline{y}$.

In order to define the S-first vertex map $N^+_{\Delta^{op},S}(F_C) \longrightarrow C$, we need to introduce a few preliminary constructions. Let $A_n \subset \mathcal{O}(\Delta^n)$ be the sub-simplicial set where a k-simplex $x_0y_0 \to \ldots \to x_ky_k$ is in

A_n if and only if $x_k \leq y_0$. For the reader's aid we draw a picture of the inclusion $A_n \subset \mathcal{O}(\Delta^n)$ for $n = 2$, where dashed edges are not in A_2:



12.12. **Lemma.** *The inclusion* $A_n \longrightarrow \mathcal{O}(\Delta^n)$ *is inner anodyne.*

Proof. In this proof we adopt the notation $[x_0y_0, ..., x_ky_k]$ for a k-simplex of $\mathcal{O}(\Delta^n)$. Let E be the collection of edges $[ab, xy]$ in $\mathcal{O}(\Delta^n)$ where $x > b$, and choose a total ordering $\leq$ on E such that if we have a factorization

$$\begin{array}{ccc} ab & \longrightarrow & xy \\ \downarrow & & \downarrow \\ a'b' & \longrightarrow & x'y' \end{array}$$

then $[a'b', x'y'] \leq [ab, xy]$. Index edges in E by $I = \{0, ..., N\}$. Define simplicial subsets $A_{n,i}$ of $\mathcal{O}(\Delta^n)$ such that $A_{n,i}$ is obtained by expanding A_n to contain every k-simplex $[x_0y_0, ..., x_ky_k]$ with $[x_0y_0, x_ky_k]$ in $E_{<i}$. We will show that each inclusion $A_{n,i} \longrightarrow A_{n,i+1}$ is inner anodyne. We may divide the nondegenerate k-simplices $[x_0y_0, x_1y_1, ..., x_ky_k]$ in $A_{n,i+1}$ but not in $A_{n,i}$ into six classes:

- $A1$: $x_1y_1 \neq x_0(y_0+1)$ and $y_1 > y_0$.
- $A2$: $x_1y_1 = x_0(y_0+1)$.
- $B1$: $x_1y_1 = (x_0+1)y_0$, $y_2 > y_0$, and $x_2y_2 \neq (x_0+1)(y_0+1)$.
- $B2$: $x_1y_1 = (x_0+1)y_0$ and $x_2y_2 = (x_0+1)(y_0+1)$.
- $C1$: $x_1y_1 \neq (x_0+1)y_0$ and $y_1 = y_0$.
- $C2$: $x_1y_1 = (x_0+1)y_0$ and $y_2 = y_0$.

We have bijections between classes of form 1 and classes of form 2 given by

- A: $[x_0y_0, x_1y_1, ..., x_ky_k] \mapsto [x_0y_0, x_0(y_0+1), x_1y_1, ..., x_ky_k]$.
- B: $[x_0y_0, x_0+1y_1, x_2y_2, ..., x_ky_k] \mapsto [x_0y_0, (x_0+1)y_0, (x_0+1)(y_0+1), x_2y_2, ..., x_ky_k]$.
- C: $[x_0y_0, x_1y_1, ..., x_ky_k] \mapsto [x_0y_0, (x_0+1)y_0, x_1y_1, ..., x_ky_k]$.

Moreover, this identifies simplices in a class of form 1 as inner faces of simplices in the corresponding class of form 2. Let P be the collection of pairs $\tau \subset \tau'$ of nondegenerate $k-1$ and k-simplices matched by this bijection. Choose a total ordering on P where pairs are ordered first by the dimension of the smaller simplex, and then by $A < B < C$, and then randomly. Let $J = \{0, ..., M\}$ be the indexing set for P. We define a sequence of inner anodyne maps

$$A_{n,i} = A_{n,i,0} \longrightarrow A_{n,i,1} \longrightarrow ... \longrightarrow A_{n,i,M+1} = A_{n,i+1}$$

such that $A_{n,i,j+1}$ is obtained from $A_{n,i,j}$ by attaching the jth pair $\tau \subset \tau'$ along an inner horn. For this to be valid, we need the other faces of τ' to already be in $A_{n,i,j}$. The ordering on E was chosen so that the outer faces of τ' are in $A_{n,i}$. The argument for the inner faces proceeds by cases:

- τ' is in class $A2$: The other inner faces are also in class $A2$ since they contain $x_0(y_0+1)$, hence were added at some earlier stage.
- τ' is in class $B2$: The other inner faces of $[x_0y_0, (x_0+1)y_0, (x_0+1)(y_0+1), x_2y_2, ..., x_ky_k]$ are all in class $B2$, except for $[x_0y_0, (x_0+1)(y_0+1), x_2y_2, ..., x_ky_k]$, which is in class $A1$. Both of these were added at an earlier stage.
- τ' is in class $C2$: The other inner faces are in class $C2$ or $B1$ since they contain $(x_0+1)y_0$, hence were added at some earlier stage.

$\square$

Let $E_n \subset (A_n)_1 \subset \mathcal{O}(\Delta^n)_1$ be the subset of edges $x_0y_0 \to x_1y_1$ where $y_0 = y_1$. Define simplicial sets C' and C'' to be the pullbacks

$$\begin{array}{ccc} C'_\bullet & \longrightarrow & \mathrm{Hom}((\mathcal{O}(\Delta^\bullet), E_\bullet), {}_\natural C) \\ \downarrow & & \downarrow \\ \mathrm{Hom}(\Delta^\bullet, S) & \xrightarrow{\mathrm{ev}_0^*} & \mathrm{Hom}(\mathcal{O}(\Delta^\bullet), S) \end{array}, \quad \begin{array}{ccc} C''_\bullet & \longrightarrow & \mathrm{Hom}((A_\bullet, E_\bullet), {}_\natural C) \\ \downarrow & & \downarrow \\ \mathrm{Hom}(\Delta^\bullet, S) & \xrightarrow{\mathrm{ev}_0^*} & \mathrm{Hom}(A_\bullet, S). \end{array}$$

We now show that the map $C' \longrightarrow C''$ induced by precomposition by $A_\bullet \longrightarrow \mathcal{O}(\Delta^\bullet)$ is a trivial Kan fibration. Indeed, in order to solve the lifting problem

$$\begin{array}{ccc} \partial\Delta^n & \longrightarrow & C' \\ \downarrow & \nearrow & \downarrow \\ \Delta^n & \longrightarrow & C'' \end{array}$$

we must supply a lift

$$\begin{array}{ccc} A_n \bigcup_{\cup A_{n-1}} (\bigcup \mathcal{O}(\Delta^{n-1})) & \longrightarrow & C \\ \downarrow & \nearrow & \downarrow \\ \mathcal{O}(\Delta^n) & \longrightarrow & S \end{array}$$

and the left vertical map is a trivial cofibration by Lemma 12.12. Let $\sigma : C'' \longrightarrow C'$ be any section. Also let $\delta : C' \longrightarrow C$ be the map induced by precomposition by the identity section $\Delta^\bullet \longrightarrow \mathcal{O}(\Delta^\bullet)$.

Define a map $\upsilon_{C,S} : N^+_{\Delta^{op},S}(F_C) \longrightarrow C$ over S as follows: the data of an n-simplex of $N^+_{\Delta^{op},S}(F_C)$ consists of

- an n-simplex $\Delta^{a_0} \leftarrow ... \leftarrow \Delta^{a_n}$ in Δ^{op} (so we have maps $f_{ij} : \Delta^{a_j} \longrightarrow \Delta^{a_i}$ for $i \leq j$);
- an n-simplex $s_\bullet : \Delta^n \longrightarrow S$;
- a choice of a_0-simplex $\sigma_0 \in C_{a_0}$;
- for $0 \leq i \leq n$, a map $\gamma_i : \Delta^i \longrightarrow \underline{\sigma_i}$, where $\sigma_i = \sigma_0 \circ f_{0i}$

such that for all $0 \leq i \leq j \leq n$, the diagram

$$\begin{array}{ccc} \Delta^i & \xrightarrow{\gamma_i} & \underline{\sigma_i} \\ {\scriptstyle \{0,\dots,i\}\subset[j]}\downarrow & & \downarrow {\scriptstyle f_{ij}^*} \\ \Delta^j & \xrightarrow{\gamma_j} & \underline{\sigma_j} \\ & {\scriptstyle (s_\bullet)|_{\{0,\dots,j\}}}\searrow & \downarrow \\ & & S \end{array}$$

commutes. Let $\overline{\gamma_i} : \Delta^i \times \Delta^{a_i} \times \Delta^1 \longrightarrow C$ denote the adjoint map.

We now define a map $A_n \longrightarrow C$ to be that uniquely specified by sending for all $0 \leq k \leq n$ the rectangle $\Delta^k \times \Delta^{n-k} \subset A_n$ given by $00 \mapsto 0k$ and $k(n-k) \mapsto kn$ to

$$\Delta^k \times \Delta^{n-k} \xrightarrow{\mathrm{id}\times(\lambda a)_k} \Delta^k \times \Delta^{a_k} \times \{1\} \xrightarrow{\overline{\gamma_i}|_{\{1\}}} C$$

where the maps $(\lambda a)_k$ are obtained from the first vertex section of $W \longrightarrow \Delta^{op}$ restricted to $a_\bullet$ as before. One may check that the composite $A_n \longrightarrow C \longrightarrow S$ factors as $A_n \longrightarrow \Delta^n \xrightarrow{s_\bullet} S$, so this defines a n-simplex of C''. This procedure is natural in $\Delta^n \in \Delta$, so yields a map $N^+_{\Delta^{op},S}(F_C) \longrightarrow C''$. Finally, postcomposition by $\delta \circ \sigma : C'' \longrightarrow C$ define our desired map $\upsilon_{C,S}$. By Proposition 12.8, $N^+_{\Delta^{op},S}(F_C) \xrightarrow{\pi'} S$ is an S-category with an edge π'-cocartesian if and only if it is degenerate when projected to Δ^{op}. These edges are evidently sent to π-cocartesian edges in C, so υ_C is a S-functor.

12.13. **Theorem.** *The S-first vertex map $\upsilon_{C,S} : N^+_{\Delta^{op},S}(F_C) \longrightarrow C$ is fiberwise a weak homotopy equivalence. Moreover, $\upsilon_{C,S}$ is S-final if either $C \longrightarrow S$ is a left fibration, or S is equivalent to the nerve of a 1-category.*

Proof. Let $t \in S$ be an object and $i_t : \{t\} \longrightarrow S$ the inclusion. Then $N^+_{\Delta^{op},S}(F_C)_t \cong N^+_{\Delta^{op}}(i_t^* F_C)$. We have a map

$$N^+_{\Delta^{op}}(i_t^* F_C) \longrightarrow \Delta^{op}_{/C} \cong N^+_{\Delta^{op}}(C_\bullet)$$

of left fibrations over Δ^{op} induced by the natural transformation $i_t^* F_C \longrightarrow C_\bullet$ which collapses each $\underline{\sigma} \times_S \{t\}$ to a point. Moreover, this natural transformation is objectwise a Kan fibration, so the map itself is a left fibration. Also define a map

$$N^+_{\Delta^{op}}(i_t^* F_C) \longrightarrow (S^{/t})^{op}$$

as follows: in the above notation, the γ_0 map in the data of an n-simplex $(a_\bullet, \gamma_i : \Delta^i \longrightarrow \underline{\sigma_i} \times_S \{t\})$ yields a map $\pi\gamma_0 : \Delta^{a_0} \longrightarrow \mathcal{O}(S) \times_S \{t\} = S^{/t}$, and we send the n-simplex to

$$\Delta^n \xrightarrow{(\lambda a^{rev})_0} (\Delta^{a_0})^{op} \xrightarrow{(\pi\gamma_0)^{op}} (S^{/t})^{op}$$

where $a_\bullet^{rev}$ is $(\Delta^{a_0})^{op} \leftarrow \ldots \leftarrow (\Delta^{a_n})^{op}$. Using these maps we obtain a commutative square

$$\begin{array}{ccc} N^+_{\Delta^{op}}(i_t^* F_C) & \longrightarrow & C^{op} \times_{S^{op}} (S^{/t})^{op} \\ \big\downarrow & & \big\downarrow \\ \Delta^{op}_{/C} & \xrightarrow{\mu_C^{op}} & C^{op}. \end{array}$$

We claim that the map

$$\theta_{C,t} : N^+_{\Delta^{op}}(i_t^* F_C) \longrightarrow (\Delta^{op}_{/C}) \times_{C^{op}} (C \times_S S^{/t})^{op}$$

is a categorical equivalence. Since $\theta_{C,t}$ is a map of left fibrations over $\Delta^{op}_{/C}$, it suffices to check that for every object $\sigma \in \Delta^{op}_{/C}$, the map on fibers

$$\underline{\sigma} \times_S \{t\} \longrightarrow (S^{op})^{t/} \times_{S^{op}} \{\pi\sigma(n)\} \simeq \{\pi\sigma(n)\} \times_S S^{/t}$$

is a homotopy equivalence. But this is the pullback of the trivial Kan fibration of Lemma 12.10 over $\{t\}$.

We next define a map $N^+_{\Delta^{op}}(i_t^* F_C) \longrightarrow S^{/t}$ by sending $(a_\bullet, \gamma_i)$ to $\pi\gamma_0 \circ (\lambda a)_0$. Then the outer rectangle

$$\begin{array}{ccccc} N^+_{\Delta^{op}}(i_t^* F_C) & \overset{\upsilon'_{C,t}}{\dashrightarrow} & C \times_S S^{/t} & \longrightarrow & S^{/t} \\ \big\downarrow & & \big\downarrow & & \big\downarrow \\ \Delta^{op}_{/C} & \xrightarrow{\upsilon_C} & C & \xrightarrow{\pi} & S \end{array}$$

commutes so we obtain the dotted map $\upsilon'_{C,t}$.

Next, we choose a section P of the trivial Kan fibration $\mathcal{O}^{cocart}(C) \longrightarrow C \times_S \mathcal{O}(S)$ which restricts to the identity section on C. P restricts to a map $P_t : C \times_S S^{/t} \longrightarrow \mathcal{O}^{cocart}(C) \times_S \{t\}$, and it is tedious but straightforward to construct a homotopy between the composition $(\mathrm{ev}_1 P_t) \circ \upsilon'_{C,t}$ and $(\upsilon_{C,S})_t$. Finally, we define a map $\upsilon''_{C,t} : \Delta^{op}_{/C \times_S S^{/t}} \longrightarrow N^+_{\Delta^{op}}(i_t^* F_C)$ as follows: given an n-simplex

$$\begin{array}{ccccc} \Delta^{a_0} & \longleftarrow & \ldots & \longleftarrow & \Delta^{a_n} \\ \big\downarrow{\scriptstyle \tau_0} & & \swarrow{\scriptstyle \tau_n} & & \\ C \times_S S^{/t} & & & & \end{array}$$

let $\sigma_i = \mathrm{pr}_C \circ \tau_i$, and define $\gamma_i : \Delta^i \longrightarrow \underline{\sigma_i} \times_S \{t\}$ as the composition of the projection to Δ^0 and the adjoint of the map $P_t \circ \tau_i$. Then $(a_\bullet, \gamma_i)$ assembles to yield an n-simplex of $N^+_{\Delta^{op}}(i_t^* F_C)$.

Unwinding the definitions of the various maps, we identify the composition $\upsilon'_{C,t} \circ \upsilon''_{C,t}$ as given by $\upsilon_{C \times_S S^{/t}}$, and the composition $\theta_{C,t} \circ \upsilon''_{C,t}$ as given by the map $\Delta^{op}_{/\,\mathrm{pr}_C}$ to the factor $\Delta^{op}_{/C}$ and the map

$(\mu_{C\times_S S^{/t}})^{op}$ to the factor $(C \times_S S^{/t})^{op}$. By Proposition 12.2 and the fact that final maps pull back along cocartesian fibrations, we deduce that in

$$\Delta^{op}_{/C\times_S S^{/t}} \longrightarrow \Delta^{op}_{/C} \times_{C^{op}} (C \times_S S^{/t})^{op} \longrightarrow (C \times_S S^{/t})^{op}$$

the long composition and the second map are both final. Consequently, $\theta_{C,t} \circ \upsilon''_{C,t}$ is a weak homotopy equivalence. Moreover, if S is equivalent to the nerve of a 1-category then $\theta_{C,t} \circ \upsilon''_{C,t}$ is a categorical equivalence, as may be verified by checking that the map is a fiberwise equivalence over $\Delta^{op}_{/C}$. Since $\theta_{C,t}$ is a categorical equivalence, $\upsilon''_{C,t}$ is then a weak homotopy equivalence resp. a categorical equivalence. Since $\upsilon_{C\times_S S^{/t}}$ is final, $\upsilon'_{C,t}$ is then a weak homotopy equivalence resp. final.

For the last step, let $j_t : C_t \longrightarrow C \times_S S^{/t}$ denote the inclusion. As the inclusion of the fiber over a final object into a cocartesian fibration, j_t is final. $(\mathrm{ev}_1 P_t) \circ j_t = \mathrm{id}_{C_t}$, so by right cancellativity of final maps, $\mathrm{ev}_1 P_t$ is final. We conclude that $(\upsilon_{C,S})_t$ is a weak homotopy equivalence resp. final. In addition, if $C \longrightarrow S$ is a left fibration, $(\upsilon_{C,S})_t$ has target a Kan complex, so is final by [12, Lemma 2.3.4.6]. Invoking the S-cofinality Theorem 6.7, we conclude the proof. □

12.14. **Remark.** The above proof that the S-first vertex map $\upsilon_{C,S}$ is final in special cases hinges upon the finality of the map $\theta_{C,t} \circ \upsilon''_{C,t}$. We believe, but are currently unable to prove, that this map is always final.

We conclude this section with our main application to decomposing S-colimits.

12.15. **Corollary.** *Suppose that S^{op} admits multipullbacks. Then C is S-cocomplete if and only C admits all S-coproducts and geometric realizations.*

Proof. We prove the if direction, the only if direction being obvious. Let K be a $S^{s/}$-category and $p : K \longrightarrow C_{\underline{s}}$ a $S^{s/}$-diagram. First suppose that $K \longrightarrow S^{s/}$ is a left fibration. Consider the diagram

$$\begin{array}{ccc} N^+_{\Delta^{op},S^{s/}}(F_K) \xrightarrow{\upsilon_{K,S^{s/}}} K \xrightarrow{p} C_{\underline{s}} \\ \downarrow{\rho} \\ \Delta^{op} \times S^{s/}. \end{array}$$

By Theorem 12.13, the $S^{s/}$-colimit of p is equivalent to that of $p\circ \upsilon_{K,S^{s/}}$. Since ρ is S-cocartesian, by Theorem 9.15 the $S^{s/}$-left Kan extension of $p\circ\upsilon_{K,S^{s/}}$ along ρ exists provided that for all $n \in \Delta^{op}$ and $f : s \to t$, the $S^{t/}$-colimit exists for $(p\circ\upsilon_{K,S^{s/}})_{\underline{(n,f)}}$. To understand the domain of this map, note that because the pullback of ρ along $f^* : \Delta^{op} \times S^{t/} \longrightarrow \Delta^{op} \times S^{s/}$ is given by $N^+_{\Delta^{op},S^{t/}}(f^*F_K)$, the assumption that S^{op} admits multipullbacks ensures that the $\underline{(n,f)}$-fibers of ρ decompose as coproducts of representable left fibrations. Therefore, these colimits exist since C is assumed to admit S-coproducts. Now by transitivity of left $S^{s/}$-Kan extensions, the $S^{s/}$-colimit of $p \circ \upsilon_{K,S^{s/}}$ is equivalent to that of $\rho_!(p \circ \upsilon_{K,S^{s/}})$, and this exists since C is assumed to admit geometric realizations.

Now suppose that $K \longrightarrow S^{s/}$ is any cocartesian fibration. Consider the diagram

$$\begin{array}{ccc} \widetilde{\iota\mathrm{Fun}}_{\Delta^{op}\times S^{s/}}(W \times S^{s/}, \Delta^{op} \times K) \xrightarrow{\Upsilon'_{K,S^{s/}}} K \xrightarrow{p} C_{\underline{s}} \\ \downarrow{\rho'} \\ \Delta^{op} \times S^{s/}. \end{array}$$

By Theorem 12.6, the $S^{s/}$-colimit of p is equivalent to that of $p \circ \Upsilon'_{K,S^{s/}}$. By Proposition 9.7, the $\underline{(n,f)}$-fiber of ρ' is equivalent to $\iota\underline{\mathrm{Fun}}_{S^{t/}}(\Delta^n \times S^{t/}, K \times_{S^{s/}} S^{t/})$, which in any case remains a left fibration. We just showed that for all $t \in S$, $C_{\underline{t}}$ admits $S^{t/}$-colimits indexed by left fibrations. We are thereby able to repeat the above proof in order to show that the $S^{s/}$-colimit of p exists. □

13. Appendix: Fiberwise fibrant replacement

In this appendix, we formulate a result (Proposition 13.4) which will allow us to recognize a map as a cocartesian equivalence if it is a marked equivalence on the fibers. We begin by introducing a marked variant of Lurie's mapping simplex construction.

13.1. **Definition.** Suppose a functor $\phi : [n] \longrightarrow s\mathbf{Set}^+$, $A_0 \longrightarrow ... \longrightarrow A_n$. Define $M(\phi)$ to be the simplicial set which is the opposite of the mapping simplex construction of [10, §3.2.2], so that a m-simplex of $M(\phi)$ is given by the data of a map $\alpha : \Delta^m \longrightarrow \Delta^n$ together with a map $\beta : \Delta^m \longrightarrow A_{\alpha(0)}$. Endow $M(\phi)$ with a marking by declaring an edge $e = (\alpha, \beta)$ of $M(\phi)$ to be marked if and only if β is a marked edge of $A_{\alpha(0)}$. Note that if each A_i is given the degenerate marking, then the marking on $M(\phi)$ is that of [10, Notation 3.2.2.3].

13.2. **Lemma.** *Suppose $\eta : \phi \longrightarrow \psi$ is a natural transformation between functors $[n] \longrightarrow s\mathbf{Set}^+$ such that for all $0 \leq i \leq n$, $\eta_i : A_i \longrightarrow B_i$ is a cocartesian equivalence. Then $M(\eta) : M(\phi) \longrightarrow M(\psi)$ is a cocartesian equivalence in $s\mathbf{Set}^+_{/\Delta^n}$.*

Proof. Using the decomposition of $M(\phi)$ as the pushout

$$M(\phi') \cup_{A_0 \times \Delta^{n-1}} A_0 \times \Delta^n$$

for $\phi' : A_1 \longrightarrow ... \longrightarrow A_n$, this follows by an inductive argument in view of the left properness of $s\mathbf{Set}^+_{/\Delta^n}$. □

13.3. **Construction.** Let $X \longrightarrow \Delta^n$ be a cocartesian fibration, let σ be a section of the trivial Kan fibration $\mathcal{O}^{cocart}(X) \longrightarrow X \times_{\Delta^n} \mathcal{O}(\Delta^n)$ which restricts to the identity section on X, and let $P = \mathrm{ev}_1 \circ \sigma$ be the corresponding choice of pushforward functor. For $0 \leq i < n$, define $f_i : X_i \times \Delta^1 \longrightarrow X$ by $P \circ (\mathrm{id}_{X_i} \times f_i')$ where $f_i' : \Delta^1 \longrightarrow \mathcal{O}(\Delta^n)$ is the edge $(i = i) \longrightarrow (i \longrightarrow i+1)$, and let $\phi : X_0^\sim \longrightarrow ... \longrightarrow X_n^\sim$ be the sequence obtained from the $f_i \times \{1\}$. We will explain how to produce a map $M(\phi) \longrightarrow X$ over Δ^n via an inductive procedure. Begin by defining the map $M(\phi)_n = X_n \longrightarrow X_n$ to be the identity. Proceeding, observe that $M(\phi)$ is the pushout

$$\begin{array}{ccc} X_0 \times \Delta^{\{1,\dots,n\}} & \longrightarrow & X_0 \times \Delta^n \\ \downarrow{\scriptstyle \gamma} & & \downarrow \\ M(\phi') & \longrightarrow & M(\phi) \end{array}$$

with ϕ' the composable sequence $X_1 \longrightarrow ... \longrightarrow X_n$ and the map γ given by $X_0 \times \Delta^{n-1} \longrightarrow X_1 \times \Delta^{n-1} \longrightarrow M(\phi')$. Given a map $g' : M(\phi') \longrightarrow X$ over Δ^{n-1}, we have a commutative square

$$\begin{array}{ccc} X_0 \times \Delta^1 \cup_{X_0 \times \Delta^{\{1\}}} X_0 \times \Delta^{\{1,\dots,n\}} & \xrightarrow{(f_0,\, g' \circ \gamma)} & X \\ \downarrow & \nearrow & \downarrow \\ X_0 \times \Delta^n & \longrightarrow & \Delta^n, \end{array}$$

and the left vertical map is inner anodyne by [10, Lemma 2.1.2.3] and [10, Corollary 2.3.2.4]. Thus a dotted lift exists and we may extend g' to $g : M(\phi) \longrightarrow X$.

Note that g_i is the identity for all $0 \leq i \leq n$. Therefore, if we instead take the marking on $M(\phi)$ which arises from the degenerate marking on the X_i, then g is (the opposite of) a quasi-equivalence in the terminology of [10, Definition 3.2.2.6], hence a cocartesian equivalence in $s\mathbf{Set}^+_{/\Delta^n}$ by [10, Proposition 3.2.2.14]. Now by Lemma 13.2, g with the given marking is a cocartesian equivalence.

This construction of $M(\phi) \longrightarrow X$ enjoys a convenient functoriality property: given a cofibration $F : X \longrightarrow Y$ between cocartesian fibrations over Δ^n, we may first choose σ_X as above, and then define

σ_Y to be a lift in the diagram

$$\begin{array}{ccc} (X \times_{\Delta^n} \mathcal{O}(\Delta^n)) \cup_X Y & \xrightarrow{(F \circ \sigma_X, \iota)} & \mathcal{O}^{cocart}(Y) \\ \downarrow & \overset{\sigma_Y}{\nearrow} & \downarrow \sim \\ Y \times_{\Delta^n} \mathcal{O}(\Delta^n) & \xrightarrow{=} & Y \times_{\Delta^n} \mathcal{O}(\Delta^n). \end{array}$$

Consequently, we obtain compatible pushforward functors and a natural transformation $\eta : \phi_X \longrightarrow \phi_Y$, which yields, by a similar argument, a commutative square

$$\begin{array}{ccc} M(\phi_X) & \xrightarrow{M(\eta)} & M(\phi_Y) \\ \downarrow & & \downarrow \\ X & \xrightarrow{F} & Y. \end{array}$$

where the vertical maps are cocartesian equivalences in $s\mathbf{Set}^+_{/\Delta^n}$.

13.4. **Proposition.** *Let $p : X \longrightarrow S$ and $q : Y \longrightarrow S$ be cocartesian fibrations over S and let $F : X \longrightarrow Y$ be a S-functor. Suppose collections of edges $\mathcal{E}_X$, $\mathcal{E}_Y$ of X, Y such that*

(1) $\mathcal{E}_X$ resp. $\mathcal{E}_Y$ contains the p resp. q-cocartesian edges;
(2) For $\mathcal{E}^0_X \subset \mathcal{E}_X$ the subset of edges which are either p-cocartesian or lie in a fiber, we have that $(X, \mathcal{E}^0_X) \subset (X, \mathcal{E}_X)$ is a cocartesian equivalence in $s\mathbf{Set}^+_{/S}$, and ditto for Y;
(3) $F(\mathcal{E}_X) \subset \mathcal{E}_Y$;
(4) For all $s \in S$, $F_s : (X_s, (\mathcal{E}_X)_s) \longrightarrow (Y_s, (\mathcal{E}_Y)_s)$ is a cocartesian equivalence in $s\mathbf{Set}^+$.

Let $X' = (X, \mathcal{E}_X)$, $Y' = (Y, \mathcal{E}_Y)$, and $F' : X' \longrightarrow Y'$ be the map given on underlying simplicial sets by F. Then for all simplicial sets U and maps $U \longrightarrow S$, F'_U is a cocartesian equivalence in $s\mathbf{Set}^+_{/U}$.

Proof. Without loss of generality, we may assume that an edge e is in $\mathcal{E}_X$ if and only if either e is p-cocartesian or $p(e)$ is degenerate, and ditto for $\mathcal{E}_Y$. First suppose that F is a trivial fibration in $s\mathbf{Set}^+_{/S}$ and for all $s \in S$, F'_s reflects marked edges. Then F' is again a trivial fibration because F' has the right lifting property against all cofibrations. For the general case, factor F as $X \xrightarrow{G} Z \xrightarrow{H} Y$ where G is a cofibration and H is a trivial fibration, and let $Z' = (Z, \mathcal{E}_Z)$ for $\mathcal{E}_Z$ the collection of edges e where e is in $\mathcal{E}_Z$ if and only if $H(e)$ is in $\mathcal{E}_Y$. Then for all $s \in S$, $Z'_s \longrightarrow Y'_s$ is a trivial fibration in $s\mathbf{Set}^+$, so as we just showed $H' : Z' \longrightarrow Y'$ is a trivial fibration. We thereby reduce to the case that F is a cofibration.

Let $\mathcal{U}$ denote the collection of simplicial sets U such that for every map $U \longrightarrow S$, F'_U is a cocartesian equivalence in $s\mathbf{Set}^+_{/U}$. We need to prove that every simplicial set belongs to $\mathcal{U}$. For this, we will verify the hypotheses of [10, Lemma 2.2.3.5]. Conditions (i) and (ii) are obvious, condition (iv) follows from left properness of the cocartesian model structure and [12, Proposition B.2.9], and condition (v) follows from the stability of cocartesian equivalences under filtered colimits and [12, Proposition B.2.9]. It remains to check that every n-simplex belongs to $\mathcal{U}$, so suppose $S = \Delta^n$. Let

$$\begin{array}{ccc} M(\phi_X) & \xrightarrow{M(\eta)} & M(\phi_Y) \\ \downarrow & & \downarrow \\ X & \xrightarrow{F} & Y \end{array}$$

be as in Construction 13.3. Let ϕ'_X be the sequence $X'_0 \longrightarrow ... \longrightarrow X'_n$, where the maps are the same as in ϕ_X, and similarly define ϕ'_Y and η'. Then we have pushout squares

$$\begin{array}{ccc} M(\phi_X) & \longrightarrow & M(\phi'_X) \\ \downarrow & & \downarrow \\ X & \longrightarrow & X'' \end{array}, \qquad \begin{array}{ccc} M(\phi_Y) & \longrightarrow & M(\phi'_Y) \\ \downarrow & & \downarrow \\ Y & \longrightarrow & Y'' \end{array}$$

with all four vertical maps cocartesian equivalences in $s\mathbf{Set}^+_{/\Delta^n}$. Here we replace X' by X'', which has the same underlying simplicial set X but more edges marked with $X' \subset X''$ left marked anodyne, so that the vertical maps $M(\phi'_X) \longrightarrow X''$ are defined and the squares are pushout squares (again, ditto for Y''). Note that F defines a map $F'' : X'' \longrightarrow Y''$.

Finally, we have the commutative square

$$\begin{array}{ccc} M(\phi'_X) & \xrightarrow{M(\eta')} & M(\phi'_Y) \\ \downarrow & & \downarrow \\ X'' & \xrightarrow{F''} & Y''. \end{array}$$

By assumption, $\eta' : \phi'_X \longrightarrow \phi'_Y$ is a natural transformation through cocartesian equivalences in $s\mathbf{Set}^+$. By Lemma 13.2, $M(\eta')$ is a cocartesian equivalence in $s\mathbf{Set}^+_{/\Delta^n}$. We deduce that F'', hence F', is as well. $\square$

13.5. **Remark.** By a simple modification of the above arguments, we may further prove that for any marked simplicial set $A \longrightarrow S$, F'_A is a cocartesian equivalence in $s\mathbf{Set}^+_{/A}$. We leave the details of this to the reader.

PARAMETRIZED HIGHER CATEGORY THEORY II: UNIVERSAL CONSTRUCTIONS

JAY SHAH

Abstract. We develop parametrized generalizations of a number of fundamental concepts in the theory of ∞-categories, including factorization systems, free fibrations, exponentiable fibrations, relative colimits and relative Kan extensions, filtered and sifted diagrams, and the universal constructions **Ind** and $\mathbf{P}^{\Sigma}$.

Contents

1. Introduction

In this paper, we continue our development of the foundations of *parametrized* (i.e., *indexed*) higher category theory from [Sha21]. Let $\mathcal{T}$ be an ∞-category.

1.1. **Definition.** A $\mathcal{T}$-∞-*category* is a cocartesian fibration $\mathcal{C} \longrightarrow \mathcal{T}^{\mathrm{op}}$. Given two $\mathcal{T}$-∞-categories $\mathcal{C}$ and $\mathcal{D}$, a $\mathcal{T}$-*functor* $F : \mathcal{C} \longrightarrow \mathcal{D}$ is a morphism of cocartesian fibrations, i.e., a functor over $\mathcal{T}^{\mathrm{op}}$ that preserves cocartesian edges.

1.2. **Warning.** In [Sha21], we set $S = \mathcal{T}^{\mathrm{op}}$ and instead spoke of S-∞-categories as cocartesian fibrations $\mathcal{C} \longrightarrow S$. As this is purely an issue of nomenclature, we will not hesitate in referring to results from [Sha21] with our opposite convention in force.

The basic idea of parametrized higher category theory is to develop a theory of ∞-categories internal to the $(\infty, 2)$-category of $\mathcal{T}$-∞-categories. The most fundamental new complication that arises is that of a broader notion of *point*; points should now be thought of as encompassing all the corepresentable left fibrations over $\mathcal{T}^{\mathrm{op}}$. For example, taking $\mathcal{T} = \mathbf{O}_G$ to be the orbit category of a finite group, the theory of G-colimits essentially amalgamates the usual theory of colimits together with that of coproducts indexed by G-orbits.[1] Our original motivation for this project lay in the necessity of having robust ∞-categorical foundations for equivariant homotopy theory – see [BDG+16] and the introduction of [Sha21] for more details on this. However, nothing in [Sha21] or this paper is specific to that application. In principle, the foundational work that we undertake here should prove useful wherever classical indexed category theory has found application, or for base ∞-categories $\mathcal{T}$ of algebro-geometric origin (e.g., in a motivic context). It

Date: January 11, 2022.

[1]See Theorem B for a precise statement.

will also be essential for our development of the theory of *parametrized* ∞*-operads* in [NS], which underpins the work of Horev and his collaborators [Hor19, HHK$^+$20] on equivariant factorization homology.

Recall that in [Sha21] we accomplished the following primary objectives:

(1) We introduced the concepts of $\mathcal{T}$-(co)limits and $\mathcal{T}$-Kan extensions.[2] We also proved the basic existence and uniqueness theorem for $\mathcal{T}$-Kan extensions (cf. [Sha21, Thm. 10.3] and [Sha21, Thm. 10.5]).

(2) Say that $\mathcal{T}$ is *orbital* if its finite coproduct completion $\mathbf{F}_{\mathcal{T}}$ admits pullbacks. Supposing that $\mathcal{T}$ is orbital, we proved as [Sha21, Cor. 12.15] that a $\mathcal{T}$-∞-category $\mathcal{C}$ is $\mathcal{T}$-cocomplete [Sha21, Def. 5.13] if and only if $\mathcal{C}$ admits all $\mathcal{T}$-coproducts [Sha21, Def. 5.10], fiberwise geometric realizations, and the restriction functors preserve geometric realizations. This was done by a $\mathcal{T}$-colimit decomposition technique in the form of the parametrized Bousfield–Kan formula; cf. [Sha21, Thm. 12.6] and [Sha21, Thm. 12.13] coupled with the parametrized Quillen's Theorem A [Sha21, Thm. 6.7].

(3) We proved a parametrized Yoneda lemma [Sha21, Lem. 11.1] and subsequently established the universal property of the $\mathcal{T}$-∞-category of presheaves [Sha21, Thm. 11.5].

For more involved applications, we need to establish generalizations of all three of these results. Firstly, recall that Lurie in [Lur09, §4.3] set up a theory of *relative Kan extensions.* The idea is that given a commutative diagram

$$\begin{array}{ccc} \mathcal{C} & \xrightarrow{F} & \mathcal{E} \\ {\scriptstyle i}\downarrow & \nearrow & \downarrow{\scriptstyle \pi} \\ \mathcal{D} & \longrightarrow & \mathcal{B} \end{array}$$

of ∞-categories, one can give a pointwise criterion for the existence of an initial filler $i_! F$. If π is in addition a cocartesian fibration, then as a corollary one sees that $i_! F$ always exists if we suppose that for all objects $b \in \mathcal{B}$, the fiber $\mathcal{E}_b$ admits all colimits, and for all morphisms $f : b \longrightarrow b'$, the pushforward functor $f_! : \mathcal{E}_b \longrightarrow \mathcal{E}_{b'}$ preserves all colimits.

We will establish the theory of *relative* $\mathcal{T}$*-colimits* and *relative* $\mathcal{T}$*-left Kan extensions* and thereby obtain a generalization of Lurie's result in the parametrized setting in the form of Theorem 6.2.[3] Since the definitions of relative $\mathcal{T}$-colimit and relative $\mathcal{T}$-left Kan extension are technically involved (cf. Definition 5.1 and Definition 6.1), at this point we will only state a simplified corollary of our main existence result that nonetheless covers the case of most relevance. To formulate the analogous existence criterion in the parametrized context, we need the notion of a *parametrized fiber* of a $\mathcal{T}$-functor:

1.3. **Definition** ([Sha21, Notn. 2.29]). Let $\mathcal{B}$ be a $\mathcal{T}$-∞-category, $b \in \mathcal{B}_t$ an object, and let $\mathrm{Ar}^{cocart}(\mathcal{B})$ be the full subcategory of $\mathrm{Ar}(\mathcal{B})$ on the cocartesian edges in $\mathcal{B}$. We let $\underline{b} := \{b\} \times_{\mathcal{B},\mathrm{ev}_0} \mathrm{Ar}^{cocart}(\mathcal{B})$. Note then that the functor $\underline{b} \longrightarrow (\mathcal{T}^{/t})^{\mathrm{op}} \cong \{t\} \times_{\mathcal{T}^{\mathrm{op}}} \mathrm{Ar}(\mathcal{T}^{\mathrm{op}})$ induced by the structure map of $\mathcal{B}$ is a trivial fibration [Sha21, Lem. 12.10] and $\mathrm{ev}_1 : \underline{b} \longrightarrow \mathcal{B}$ is a $\mathcal{T}$-functor covering $(\mathcal{T}^{/t})^{\mathrm{op}} \longrightarrow \mathcal{T}^{\mathrm{op}}$.

Now suppose $\pi : \mathcal{E} \longrightarrow \mathcal{B}$ is a $\mathcal{T}$-functor. The *parametrized fiber* of π over b is the $\mathcal{T}^{/t}$-∞-category

$$\mathcal{E}_{\underline{b}} := \underline{b} \times_{\mathrm{ev}_1, \mathcal{B}, \pi} \mathcal{E}.$$

Theorem A. *Suppose we have a commutative diagram of* $\mathcal{T}$*-*∞*-categories*

$$\begin{array}{ccc} \mathcal{C} & \longrightarrow & \mathcal{E} \\ {\scriptstyle i}\downarrow & \nearrow & \downarrow{\scriptstyle \pi} \\ \mathcal{D} & \longrightarrow & \mathcal{B} \end{array}$$

in which i *is the inclusion of a full* $\mathcal{T}$*-subcategory* [Sha21, Def. 2.2] *and* π *is in addition a cocartesian fibration. Consider the restriction functor*

$$i^* : \mathrm{Fun}_{/\mathcal{B},\mathcal{T}}(\mathcal{D}, \mathcal{E}) \longrightarrow \mathrm{Fun}_{/\mathcal{B},\mathcal{T}}(\mathcal{C}, \mathcal{E})$$

where $\mathrm{Fun}_{/\mathcal{B},\mathcal{T}}(-,-)$ *denotes the full subcategory of* $\mathrm{Fun}_{/\mathcal{B}}(-,-)$ *spanned by the* $\mathcal{T}$*-functors. Suppose that for all* $b \in \mathcal{B}_t$*, the parametrized fiber* $\mathcal{E}_{\underline{b}}$ *admits all* $\mathcal{T}^{/t}$*-colimits, and for all* $f : b \longrightarrow b' \in \mathcal{B}_t$*, the induced pushforward* $\mathcal{T}^{/t}$*-functor* $f_! : \mathcal{E}_{\underline{b}} \longrightarrow \mathcal{E}_{\underline{b'}}$ *preserves all* $\mathcal{T}^{/t}$*-colimits. Then* i^* *admits a left adjoint* $i_!$*. Moreover, the unit transformation* $\mathrm{id} \Rightarrow i^* i_!$ *is an equivalence, so* $i_!$ *is fully faithful.*

[2] We give a rapid review of these concepts in Section 2.

[3] Of course, one may dualize appropriately to obtain analogous results involving relative $\mathcal{T}$-limits and relative $\mathcal{T}$-right Kan extensions; cf. [Sha21, Cor. 5.25].

1.4. **Remark.** As with the ordinary theory of Kan extensions, the full faithfulness assertion in Theorem A is where the pointwise formula for $i_!$ comes into play. In particular, even if we assumed the relevant presentability hypotheses, it would not suffice to appeal to the adjoint functor theorem to verify this property.

Secondly, we develop the theory of $\mathcal{T}$-κ-small, $\mathcal{T}$-filtered, and $\mathcal{T}$-sifted $\mathcal{T}$-∞-categories. In order to speak of small and large simplicial sets and ∞-categories, we henceforth fix two strongly inaccessible cardinals $\delta_0 < \delta_1$.

1.5. **Convention.** For simplicity, we now also suppose throughout that the base ∞-category $\mathcal{T}$ is small.

Let **Cat** denote the (large) ∞-category of small ∞-categories and let $\mathbf{Cat}_{\mathcal{T}} := \mathbf{Cat}^{cocart}_{/\mathcal{T}^{\mathrm{op}}} \simeq \mathrm{Fun}(\mathcal{T}^{\mathrm{op}}, \mathbf{Cat})$ be the ∞-category of $\mathcal{T}$-small $\mathcal{T}$-∞-categories.[4]

1.6. **Definition** (Definition 8.2)**.** Let $\Delta_{\mathcal{T}} \subset \mathbf{Cat}_{\mathcal{T}}$ be the full subcategory spanned by the objects

$$\{\Delta^n \times \mathrm{Map}_{\mathcal{T}}(-, t)\}_{t \in \mathcal{T}, n \geq 0}.$$

Then for every regular cardinal κ, we define the full subcategory $\mathbf{Cat}_{\mathcal{T}}^{\kappa\text{-small}} \subset \mathbf{Cat}_{\mathcal{T}}$ to be the smallest full subcategory that contains $\Delta_{\mathcal{T}}$ and is closed under all colimits indexed by κ-small simplicial sets. We say that a $\mathcal{T}$-small $\mathcal{T}$-∞-category $\mathcal{C}$ is $\mathcal{T}$-*κ-small* if it belongs to $\mathbf{Cat}_{\mathcal{T}}^{\kappa\text{-small}}$. If $\kappa = \omega$, we also say that $\mathcal{C}$ is $\mathcal{T}$-*finite*.

1.7. **Remark.** Adopting the terminology of Definition 1.6 entails speaking of a host of seemingly redundant expressions such "$\mathcal{T}$-finite $\mathcal{T}$-∞-category". We avoid simply writing e.g. "finite $\mathcal{T}$-∞-category" because of the possible ambiguity as to whether, given some $\mathcal{T}$-∞-category $\mathcal{C}$, "finite" refers to $\mathcal{C}$ being finite as an ∞-category or as a $\mathcal{T}$-∞-category.

We then have the following generalization of [Sha21, Cor. 12.15], whose proof turns out to be far simpler than our earlier strategy of appealing to the parametrized Bousfield–Kan formula. We give the most useful formulation of this here; a slightly more general statement is recorded as Theorem 8.6.

Theorem B. *Suppose that $\mathcal{T}$ is orbital. Let $\mathcal{C}$ be an $\mathcal{T}$-∞-category and κ a regular cardinal. Then $\mathcal{C}$ strongly admits*[5] *all $\mathcal{T}$-κ-small $\mathcal{T}$-colimits if and only if*

(1) For every $t \in \mathcal{T}$, the fiber $\mathcal{C}_t$ admits all κ-small colimits, and for every $\alpha : s \longrightarrow t$, the restriction functor $\alpha^* : \mathcal{C}_t \longrightarrow \mathcal{C}_s$ preserves κ-small colimits.

(2) For every map $\alpha : U \longrightarrow V$ of finite $\mathcal{T}$-sets,[6] *the restriction functor $\alpha^* : \mathcal{C}_V \longrightarrow \mathcal{C}_U$ admits a left adjoint $\alpha_!$.*[7]

(3) $\mathcal{C}$ satisfies the Beck-Chevalley condition*, i.e., for every pullback square*

$$\begin{array}{ccc} U' & \xrightarrow{\beta'} & U \\ \downarrow{\scriptstyle \alpha'} & & \downarrow{\scriptstyle \alpha} \\ V' & \xrightarrow{\beta} & V \end{array}$$

in $\mathbf{F}_{\mathcal{T}}$, the mate

$$\alpha'_! \beta'^* \Rightarrow \beta^* \alpha_! : \mathcal{C}_U \longrightarrow \mathcal{C}_{V'}$$

is an equivalence.

1.8. **Remark.** Again supposing that $\mathcal{T}$ is orbital, note that by [Sha21, Prop. 5.12] $\mathcal{C}$ admits finite $\mathcal{T}$-coproducts if and only if conditions (2) and (3) in Theorem B hold. Moreover, the ordinary (∞-categorical) Bousfield–Kan formula shows that an ∞-category is cocomplete if and only if it admits coproducts and geometric realizations (cf. [Sha21, Cor. 12.3]). Taking κ to be our fixed inaccessible cardinal δ_0, we then see that the hypotheses of Theorem B are equivalent to those of [Sha21, Cor. 12.15].

[4]Since we suppose that $\mathcal{T}$ is small, a $\mathcal{T}$-∞-category $\mathcal{C}$ is $\mathcal{T}$-small if and only if $\mathcal{C}$ is small.

[5]We recall this notion as Definition 2.8.

[6]A finite $\mathcal{T}$-set is defined to be an object of the finite coproduct completion $\mathbf{F}_{\mathcal{T}}$ of $\mathcal{T}$.

[7]For a finite $\mathcal{T}$-set U with orbit decomposition $U_1 \sqcup ... \sqcup U_n$, we write $\mathcal{C}_U := \prod_{i=1}^n \mathcal{C}_{U_i}$, and the contravariant functoriality in the finite $\mathcal{T}$-set is inherited from that for orbits.

1.9. **Remark.** In [Nar16], Nardin implicitly *defines* a $\mathcal{T}$-∞-category to strongly admit $\mathcal{T}$-finite $\mathcal{T}$-(co)limits[8] if conditions (1) through (3) in Theorem B are satisfied. Moreover, using his formulation, a $\mathcal{T}$-stable $\mathcal{T}$-∞-category [Nar16, Def. 7.1] by definition strongly admits all $\mathcal{T}$-finite $\mathcal{T}$-colimits and $\mathcal{T}$-finite $\mathcal{T}$-limits. One practical consequence of Theorem B is that $\mathcal{T}$-stable $\mathcal{T}$-∞-categories then strongly admit $\mathcal{T}$-(co)limits indexed by an *a priori* larger class of $\mathcal{T}$-diagrams; for instance, when $\mathcal{T} = \mathbf{O}_G$ this includes those G-spaces that admit the structure of a finite G-CW complex.

Moving onto the theory of $\mathcal{T}$-κ-filtered and $\mathcal{T}$-sifted $\mathcal{T}$-∞-categories, we may make the following definitions as the evident parametrized generalizations of [Lur09, Def. 5.3.1.7] and [Lur09, Def. 5.5.8.1].

1.10. **Definition** (Definition 8.8)**.** Let $\mathcal{J}$ be a $\mathcal{T}$-∞-category and let κ be a regular cardinal. We say that $\mathcal{J}$ is $\mathcal{T}$-*κ-filtered* if for all $t \in \mathcal{T}$ and $\mathcal{T}^{/t}$-κ-small $\mathcal{K}$, every $\mathcal{T}^{/t}$-functor $p : \mathcal{K} \longrightarrow \mathcal{J}_{\underline{t}}$ admits an extension to a $\mathcal{T}^{/t}$-functor $\overline{p} : \mathcal{K}^{\underline{\triangleright}} \longrightarrow \mathcal{J}_{\underline{t}}$.[9]

1.11. **Notation.** For a finite $\mathcal{T}$-set U with orbit decomposition $U_1 \sqcup ... \sqcup U_n$, we write

$$\underline{U} := \coprod_{i=1}^{n} (\mathcal{T}^{\mathrm{op}})^{U_i/}$$

for the $\mathcal{T}$-∞-category given by the coproduct of corepresentable left fibrations; this straightens to the presheaf $\mathrm{Map}_{\mathbf{F}_{\mathcal{T}}}(-, U)|_{\mathcal{T}^{\mathrm{op}}}$.

Recall from [Sha21] that we write $\underline{\mathrm{Fun}}_{\mathcal{T}}(-,-)$ for the internal hom for $\mathcal{T}$-∞-categories (defined at the level of marked simplicial sets as [Sha21, Def. 3.2]); for every $t \in \mathcal{T}$ we have that $\underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{C}, \mathcal{D})_t \simeq \mathrm{Fun}_{\mathcal{T}^{/t}}(\mathcal{C}_{\underline{t}}, \mathcal{D}_{\underline{t}})$, and for every $\alpha : s \longrightarrow t$, the restriction functor α^* is given by restricting $\mathcal{T}^{/t}$-functors to $\mathcal{T}^{/s}$-functors.

1.12. **Definition** (Definition 8.14)**.** Let $\mathcal{J}$ be a $\mathcal{T}$-∞-category. Then $\mathcal{J}$ is $\mathcal{T}$-*sifted* if for all $t \in \mathcal{T}$ and finite $\mathcal{T}^{/t}$-sets U, the diagonal $\mathcal{T}^{/t}$-functor $\delta : \mathcal{J}_{\underline{t}} \longrightarrow \underline{\mathrm{Fun}}_{\mathcal{T}^{/t}}(\underline{U}, \mathcal{J}_{\underline{t}})$ is $\mathcal{T}^{/t}$-cofinal in the sense of [Sha21, Def. 6.8], i.e. δ is fiberwise cofinal.

Our main theorems about these concepts should be read as confirming the following expectation: $\mathcal{T}$-filtered and $\mathcal{T}$-sifted $\mathcal{T}$-colimits are computed as ordinary filtered and ordinary sifted colimits in the fibers. To say this precisely, we need another definition.

1.13. **Definition** (Definition 9.5)**.** Let $\mathcal{J}$ be a $\mathcal{T}$-∞-category. We say that $\mathcal{J}$ is *cofinal-constant* (cc) if for all morphisms $\alpha : s \longrightarrow t$ in $\mathcal{T}$, the restriction functor $\alpha^* : \mathcal{J}_t \longrightarrow \mathcal{J}_s$ is cofinal.

1.14. **Remark.** Let $\mathcal{J}$ be a cofinal-constant $\mathcal{T}$-∞-category and $p : \mathcal{J} \longrightarrow \mathcal{C}$ a $\mathcal{T}$-functor. Moreover, suppose that $\mathcal{T}$ has a terminal object t. Then by our hypothesis on $\mathcal{J}$ and [Sha21, Thm. 6.7], the $\mathcal{T}$-functor $\chi : \mathcal{J}_t \times \mathcal{T}^{\mathrm{op}} \longrightarrow \mathcal{J}$ uniquely determined by the inclusion $\mathcal{J}_t \subset \mathcal{J}$ is $\mathcal{T}$-cofinal. Consequently, we obtain an equivalence

$$\mathrm{colim}^{\mathcal{T}}_{\mathcal{J}} p \simeq \mathrm{colim}^{\mathcal{T}}_{\mathcal{J}_t \times \mathcal{T}^{\mathrm{op}}} p \circ \chi$$

provided that either $\mathcal{T}$-colimit exists.

Now let **Spc** denote the (large) ∞-category of small spaces and let $\underline{\mathbf{Spc}}_{\mathcal{T}}$ be the $\mathcal{T}$-∞-category of small $\mathcal{T}$-spaces [Sha21, Exm. 3.12].

Theorem C (Theorem 8.11 and Theorem 8.13)**.** *Suppose that $\mathcal{T}$ is orbital. Let $\mathcal{J}$ be a $\mathcal{T}$-∞-category and let κ be a regular cardinal. The following conditions are equivalent:*

(1) $\mathcal{J}$ is $\mathcal{T}$-κ-filtered.
(2) For all $t \in \mathcal{T}$, $\mathcal{J}_t$ is κ-filtered, and $\mathcal{J}$ is cofinal-constant.
(3) The $\mathcal{T}$-colimit $\mathcal{T}$-functor

$$\underline{\mathrm{colim}}^{\mathcal{T}}_{\mathcal{J}} : \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{J}, \underline{\mathbf{Spc}}_{\mathcal{T}}) \longrightarrow \underline{\mathbf{Spc}}_{\mathcal{T}}$$

strongly preserves $\mathcal{T}$-κ-small $\mathcal{T}$-limits.

[8]Note that Nardin writes instead "finite $\mathcal{T}$-(co)limits" for this notion and he also doesn't use the adjective "strongly"; see Remark 1.7.

[9]We recall the parametrized cone as Definition 2.2. Here, for the $\mathcal{T}^{/t}$-∞-category $\mathcal{K}$, $\mathcal{K}^{\underline{\triangleright}}$ is notation for $\mathcal{K} \star_{(\mathcal{T}^{/t})^{\mathrm{op}}} (\mathcal{T}^{/t})^{\mathrm{op}}$.

(4) For all $t \in \mathcal{T}$ *and* $\mathcal{T}^{/t}$*-*κ*-small* $\mathcal{K}$*, the diagonal* $\mathcal{T}^{/t}$*-functor*

$$\delta : \mathcal{J}_{\underline{t}} \longrightarrow \underline{\mathrm{Fun}}_{\mathcal{T}^{/t}}(\mathcal{K}, \mathcal{J}_{\underline{t}})$$

is $\mathcal{T}^{/t}$*-cofinal.*

Theorem D (Theorem 8.15)**.** *Suppose that* $\mathcal{T}$ *is orbital and let* $\mathcal{J}$ *be a* $\mathcal{T}$*-*∞*-category. The following conditions are equivalent:*

(1) $\mathcal{J}$ *is* $\mathcal{T}$*-sifted.*
(2) For all $t \in \mathcal{T}$*,* $\mathcal{J}_t$ *is sifted, and* $\mathcal{J}$ *is cofinal-constant.*
(3) The $\mathcal{T}$*-colimit* $\mathcal{T}$*-functor*

$$\underline{\mathrm{colim}}^{\mathcal{T}}_{\mathcal{J}} : \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{J}, \underline{\mathbf{Spc}}_{\mathcal{T}}) \longrightarrow \underline{\mathbf{Spc}}_{\mathcal{T}}$$

preserves finite $\mathcal{T}$*-products.*

Thirdly, building upon our earlier discussion of $\mathcal{T}$-presheaves, we introduce the universal constructions $\underline{\mathbf{Ind}}^{\kappa}_{\mathcal{T}}(\mathcal{C})$ and $\underline{\mathbf{P}}^{\Sigma}_{\mathcal{T}}(\mathcal{C})$ that freely adjoin $\mathcal{T}$-κ-filtered $\mathcal{T}$-colimits and $\mathcal{T}$-sifted $\mathcal{T}$-colimits to $\mathcal{C}$, respectively (Definition 9.9). These are essentially defined to be the minimal full $\mathcal{T}$-subcategories of $\underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C}) := \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{C}^{\mathrm{vop}}, \underline{\mathbf{Spc}}_{\mathcal{T}})$ closed under the relevant $\mathcal{T}$-colimits. However, in view of condition (2) in Theorem C and Theorem D, it turns out that $\underline{\mathbf{Ind}}^{\kappa}_{\mathcal{T}}(-)$ and $\underline{\mathbf{P}}^{\Sigma}_{\mathcal{T}}(-)$ are obtained by fiberwise application of $\mathbf{Ind}^{\kappa}$ and $\mathbf{P}^{\Sigma}$ (cf. Variant 9.8).

Our main result identifies these constructions in terms of $\mathcal{T}$-presheaves that strongly preserve certain $\mathcal{T}$-limits if $\mathcal{C}$ admits sufficiently many $\mathcal{T}$-colimits.

1.15. **Notation.** Let $\mathcal{D}$ and $\mathcal{E}$ be $\mathcal{T}$-∞-categories, and suppose in the following that $\mathcal{D}, \mathcal{E}$ strongly admit the relevant $\mathcal{T}$-(co)limits. We introduce notation for certain full $\mathcal{T}$-subcategories of $\underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{D}, \mathcal{E})$, which may be specified by indicating over each $t \in \mathcal{T}$ what $\mathcal{T}^{/t}$-functors $\mathcal{D}_{\underline{t}} \longrightarrow \mathcal{E}_{\underline{t}}$ span the fiber:

(1) $\underline{\mathrm{Fun}}^{L}_{\mathcal{T}}(\mathcal{D}, \mathcal{E})$: take those $\mathcal{T}^{/t}$-functors that strongly preserve all (small) $\mathcal{T}^{/t}$-colimits.
(2) $\underline{\mathrm{Fun}}^{\times}_{\mathcal{T}}(\mathcal{D}, \mathcal{E})$: take those $\mathcal{T}^{/t}$-functors that preserve finite $\mathcal{T}^{/t}$-products.[10]
(3) $\underline{\mathrm{Fun}}^{\sqcup}_{\mathcal{T}}(\mathcal{D}, \mathcal{E})$: take those $\mathcal{T}^{/t}$-functors that preserve finite $\mathcal{T}^{/t}$-coproducts.
(4) $\underline{\mathrm{Fun}}^{\kappa\text{-lex}}_{\mathcal{T}}(\mathcal{D}, \mathcal{E})$: take those $\mathcal{T}^{/t}$-functors that strongly preserve $\mathcal{T}$-κ-small $\mathcal{T}^{/t}$-limits.
(5) $\underline{\mathrm{Fun}}^{\kappa\text{-rex}}_{\mathcal{T}}(\mathcal{D}, \mathcal{E})$: take those $\mathcal{T}^{/t}$-functors that strongly preserve $\mathcal{T}$-κ-small $\mathcal{T}^{/t}$-colimits.

We only state the most important points here and refer the reader to the main body of the paper for the more comprehensive theorem.

Theorem E (Theorem 9.11)**.** *Suppose that* $\mathcal{T}$ *is orbital and let* $\mathcal{C}$ *be a* $\mathcal{T}$*-*∞*-category.*

(1) Suppose that $\mathcal{C}$ *admits finite* $\mathcal{T}$*-coproducts. We then have an equality*

$$\underline{\mathbf{P}}^{\Sigma}_{\mathcal{T}}(\mathcal{C}) = \underline{\mathrm{Fun}}^{\times}_{\mathcal{T}}(\mathcal{C}^{\mathrm{vop}}, \underline{\mathbf{Spc}}_{\mathcal{T}}).$$

Moreover, $\underline{\mathbf{P}}^{\Sigma}_{\mathcal{T}}(\mathcal{C})$ *is* $\mathcal{T}$*-cocomplete, and given any* $\mathcal{T}$*-cocomplete* $\mathcal{T}$*-*∞*-category* $\mathcal{D}$*, restriction along the* $\mathcal{T}$*-Yoneda embedding* $j^{\Sigma}_{\mathcal{T}} : \mathcal{C} \hookrightarrow \underline{\mathbf{P}}^{\Sigma}_{\mathcal{T}}(\mathcal{C})$ *implements an equivalence*

$$\underline{\mathrm{Fun}}^{L}_{\mathcal{T}}(\underline{\mathbf{P}}^{\Sigma}_{\mathcal{T}}(\mathcal{C}), \mathcal{D}) \xrightarrow{\simeq} \underline{\mathrm{Fun}}^{\sqcup}_{\mathcal{T}}(\mathcal{C}, \mathcal{D})$$

with inverse given by $\mathcal{T}$*-left Kan extension.*

(2) Suppose that $\mathcal{C}$ *strongly admits* $\mathcal{T}$*-*κ*-small* $\mathcal{T}$*-colimits. We then have an equality*

$$\underline{\mathbf{Ind}}^{\kappa}_{\mathcal{T}}(\mathcal{C}) = \underline{\mathrm{Fun}}^{\kappa\text{-lex}}_{\mathcal{T}}(\mathcal{C}^{\mathrm{vop}}, \underline{\mathbf{Spc}}_{\mathcal{T}}).$$

Moreover, $\underline{\mathbf{Ind}}^{\kappa}_{\mathcal{T}}(\mathcal{C})$ *is* $\mathcal{T}$*-cocomplete, and given any* $\mathcal{T}$*-cocomplete* $\mathcal{T}$*-*∞*-category* $\mathcal{D}$*, restriction along the* $\mathcal{T}$*-Yoneda embedding* $j^{\kappa}_{\mathcal{T}} : \mathcal{C} \hookrightarrow \underline{\mathbf{Ind}}^{\kappa}_{\mathcal{T}}(\mathcal{C})$ *implements an equivalence*

$$\underline{\mathrm{Fun}}^{L}_{\mathcal{T}}(\underline{\mathbf{Ind}}^{\kappa}_{\mathcal{T}}(\mathcal{C}), \mathcal{D}) \xrightarrow{\simeq} \underline{\mathrm{Fun}}^{\kappa\text{-rex}}_{\mathcal{T}}(\mathcal{C}, \mathcal{D})$$

with inverse given by $\mathcal{T}$*-left Kan extension.*

[10] Note that there is no distinction between strongly preserving and preserving finite $\mathcal{T}^{/t}$-products, and likewise for finite $\mathcal{T}^{/t}$-coproducts.

Lastly, we also lay parametrized foundations for two other important concepts in the theory of ∞-categories: *factorization systems* and *exponentiable* (i.e., *flat*) *fibrations*.[11] We defer the statements of these results to their respective sections 3 and 4. Most notably, we use the theory of $\mathcal{T}$-factorization systems to establish the universal property of the free $\mathcal{T}$-cocartesian fibration (Example 3.8), while we use the theory of $\mathcal{T}$-flat fibrations and the associated $\mathcal{T}$-*pairing construction* (Theorem-Construction 4.2) to study $\mathcal{T}$-(co)limits in a $\mathcal{T}$-∞-category of sections (Theorem 4.16).

1.16. **Remark.** In the case $\mathcal{T} = *$, our main Theorem 3.6 on parametrized factorization systems applies to give a common generalization of the proof of the universal property of the usual free cocartesian fibration ([GHN17, Thm. 4.5]) with that of the universal property of the $\mathcal{O}$-monoidal envelope for an ∞-operad $\mathcal{O}$ ([Lur17, Prop. 2.2.4.9]).[12] In [NS], we will apply Theorem 3.6 to establish the theory of $\mathcal{O}$-monoidal envelopes for a $\mathcal{T}$-∞-operad $\mathcal{O}$.

1.17. **Remark.** Our main interest in Theorem 4.16 lies in using it in [NS] to study $\mathcal{T}$-(co)limits in a $\mathcal{T}$-∞-category of $\mathcal{O}$-algebras for a $\mathcal{T}$-∞-operad $\mathcal{O}$. Also see [BH21, Prop. 7.6] for a similar type of statement in the context of normed E_∞-algebras in motivic homotopy theory.

In the appendix, we take the opportunity to give the correct[13] definition of an exponentiable fibration of ∞-operads and then the construction of $\mathcal{O}$-*promonoidal Day convolution* with respect to a base ∞-operad $\mathcal{O}^\otimes$ (Theorem-Construction 10.6). This generalizes Lurie's construction in [Lur17, §2.2.6], which supposes that the source ∞-operad in question is $\mathcal{O}$-monoidal. We saw fit to include this material here because the main lemma behind it (Lemma 10.1) is also used to establish the theory of $\mathcal{T}$-flat fibrations.

1.18. **Remark.** Vladimir Hinich has informed us that our treatment of $\mathcal{O}$-promonoidal Day convolution is a slightly reorganized version of his discussion in [Hin20, §2.8]. In particular, our Theorem-Construction 10.6 is essentially his [Hin20, Prop. 2.8.3], and Lemma 10.1 when specialized to the context of ∞-operads is his [Hin20, Lem. 2.8.4].

Notation and terminology. We collect a few miscellaneous pieces of notation and terminology from [Sha21] that we have not introduced yet in our discussion.

1.19. **Convention.** Let $X, Y \longrightarrow Z$ be maps of simplicial sets. Unless otherwise indicated, when we write $X \times_Z \mathrm{Ar}(Z) \times_Z Y$ we mean $X \times_{Z,\mathrm{ev}_0} \mathrm{Ar}(Z) \times_{\mathrm{ev}_1,Z} Y$ (i.e., evaluation at the source goes to the left and evaluation at the target goes to the right).

We will need to use the theory of marked simplicial sets in various places in this paper; see [Sha21, §2] for a review.

1.20. **Notation.** (1) Given a simplicial set X, we let $X^\flat$ be the minimal marking on X and $X^\sharp$ the maximal marking on X.
(2) If $p : X \longrightarrow S$ is a cocartesian fibration, then we let ${}_\natural X$ denote X with its p-cocartesian edges marked.

1.21. **Notation.** We will generally write $\mathcal{T}^{\mathrm{op}}$ as $*_\mathcal{T}$ when we wish to think of it as the terminal $\mathcal{T}$-∞-category.

1.22. **Definition.** Let $\mathcal{C}$ be a $\mathcal{T}$-∞-category. We define the $\mathcal{T}$-∞-*category of arrows* in $\mathcal{C}$ to be

$$\mathrm{Ar}_\mathcal{T}(\mathcal{C}) := \mathcal{T}^{\mathrm{op}} \times_{\mathrm{Ar}(\mathcal{T}^{\mathrm{op}})} \mathrm{Ar}(\mathcal{C})$$

where the map $\mathcal{T}^{\mathrm{op}} \longrightarrow \mathrm{Ar}(\mathcal{T}^{\mathrm{op}})$ is the identity section.

1.23. **Recollection** ([Sha21, Def. 4.1])**.** Let S be a simplicial set, let $\iota : \partial\Delta^1 \times S \subset \Delta^1 \times S$ be the inclusion functor, and consider the right adjoint

$$\iota_* : \mathbf{sSet}_{/\partial\Delta^1 \times S} \longrightarrow \mathbf{sSet}_{/\Delta^1 \times S}$$

[11] Some authors (e.g., Ayala and Francis [AF20]) reserve the term *exponentiable* for the homotopy invariant definition, but we will elide this distinction in our narrative here.

[12] This line of reasoning is well-known to experts and has also appeared in the literature as [AMGR17, Prop. B.1]; we thank Rune Haugseng for the pointer.

[13] If $\mathcal{O}^\otimes$ is the commutative ∞-operad, then it turns out that our earlier definition of symmetric promonoidal given in [BGS20] was insufficiently general; see Example 10.4. We thank Yonatan Harpaz for alerting us to this issue.

to pullback along ι. Then for maps $p, q : X, Y \longrightarrow S$ of simplicial sets, we define the *S-join* $X \star_S Y$ to be $\iota_*(X, Y)$; this recovers the ordinary join if $S = *$. Note that if we let $\chi : S \times \Delta^1 \longrightarrow S \star S$ be the map adjoint to $\mathrm{id}_{S\times\partial\Delta^1}$ (using the universal property of the ordinary join), then we have a canonical isomorphism

$$X \star_S Y \cong S \times \Delta^1 \underset{\chi, S\star S, p\star q}{\times} X \star Y,$$

so the S-join is the *relative join* in the sense of Lurie [Lur21, Tag 0241]. In keeping with the terminology of [Sha21], however, we will prefer to generically call this the parametrized join.

Now if $S = \mathcal{T}^{\mathrm{op}}$ and we have $\mathcal{T}$-∞-categories $\mathcal{C}$ and $\mathcal{D}$, the $\mathcal{T}^{\mathrm{op}}$-join $\mathcal{C} \star_{\mathcal{T}^{\mathrm{op}}} \mathcal{D}$ is again a $\mathcal{T}$-∞-category, and in fact the structure map to $\mathcal{T}^{\mathrm{op}} \times \Delta^1$ is a $\mathcal{T}$-functor (cf. [Sha21, Prop. 4.3]).

1.24. **Recollection** ([Sha21, Def. 8.3]). Let $\mathcal{C}$ and $\mathcal{D}$ be $\mathcal{T}$-∞-categories and let $F\colon \mathcal{C} \rightleftarrows \mathcal{D} : G$ be a relative adjunction with respect to $\mathcal{T}^{\mathrm{op}}$ [Lur17, Def. 7.3.2.2]. Then we say that $F \dashv G$ is a *$\mathcal{T}$-adjunction* if F and G are both $\mathcal{T}$-functors.

1.25. **Recollection** ([Sha21, Def. 7.1]). Let $p : \mathcal{X} \longrightarrow \mathcal{B}$ be a $\mathcal{T}$-functor. We say that p is a *$\mathcal{T}$-fibration* if p is a categorical fibration. In this case, p is *$\mathcal{T}$-cocartesian*, resp. *$\mathcal{T}$-cartesian* if

1. For every object $t \in \mathcal{T}$, $p_t : \mathcal{X}_t \longrightarrow \mathcal{B}_t$ is a cocartesian, resp. cartesian fibration.
2. For every morphism $\alpha : s \longrightarrow t$, the restriction functor $\alpha^* : \mathcal{X}_t \longrightarrow \mathcal{X}_s$ carries p_t-cocartesian, resp. p_t-cartesian edges to p_s-cocartesian, resp. p_s-cartesian edges.

If $p : \mathcal{X} \longrightarrow \mathcal{B}$ and $q : \mathcal{Y} \longrightarrow \mathcal{B}$ are two $\mathcal{T}$-cocartesian fibrations, we say that a $\mathcal{T}$-functor $F : \mathcal{X} \longrightarrow \mathcal{Y}$ over $\mathcal{B}$ is a *morphism of $\mathcal{T}$-cocartesian fibrations* if F preserves fiberwise (with respect to $\mathcal{T}$) cocartesian edges. Similarly, we have the analogous definition of a morphism of $\mathcal{T}$-cartesian fibrations.

Finally, note that p is $\mathcal{T}$-cocartesian if and only if p is a cocartesian fibration [Sha21, Rem. 7.4].

Acknowledgements. I would like to thank Denis Nardin for helpful conversations on the subject matter of this paper. I would also like to acknowledge that Dylan Wilson has obtained similar results in unpublished work. 2. Recollections on parametrized limits and colimits

In this section, we give a streamlined exposition of the concepts of parametrized (co)limits and Kan extensions introduced in [Sha21]. This is done primarily to fix notation and make this paper more self-contained. For the reader already familiar with [Sha21], the only points to bear in mind are our more concise notation for parametrized cones (Definition 2.2) and the notion of strongly admitting and preserving $\mathcal{K}$-indexed $\mathcal{T}$-colimits with respect to certain collections $\mathcal{K}$ of parametrized diagrams (Definition 2.8).

2.1. **Notation** ([Sha21, Notn. 3.5]). Let $p : \mathcal{K} \longrightarrow \mathcal{C}$ be a $\mathcal{T}$-functor. We then let

$$\sigma_p : *_{\mathcal{T}} \longrightarrow \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K}, \mathcal{C})$$

denote the cocartesian section given by adjointing the map $\mathrm{Ar}(\mathcal{T}^{\mathrm{op}})^\sharp \times_{\mathcal{T}^{\mathrm{op}}} {}_\natural\mathcal{K} \xrightarrow{\mathrm{pr}} {}_\natural\mathcal{K} \xrightarrow{p} {}_\natural\mathcal{C}$. This is an explicit choice of $\mathcal{T}$-functor corresponding to p under the equivalence

$$\mathrm{Fun}_{\mathcal{T}}(*_{\mathcal{T}}, \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K}, \mathcal{C})) \simeq \mathrm{Fun}_{\mathcal{T}}(\mathcal{K}, \mathcal{C})$$

of [Sha21, Prop. 3.4].

2.2. **Definition** (Cones and slices). Let $\mathcal{C}$ be a $\mathcal{T}$-∞-category. We let

$$\mathcal{C}^{\underline{\triangleright}} := \mathcal{C} \star_{\mathcal{T}^{\mathrm{op}}} \mathcal{T}^{\mathrm{op}}\,, \qquad \mathcal{C}^{\underline{\triangleleft}} := \mathcal{T}^{\mathrm{op}} \star_{\mathcal{T}^{\mathrm{op}}} \mathcal{C}$$

denote the *$\mathcal{T}$-right* and *$\mathcal{T}$-left cones* on $\mathcal{C}$. We also write $v : *_{\mathcal{T}} \subset \mathcal{C}^{\underline{\triangleright}}$ or $\mathcal{C}^{\underline{\triangleleft}}$ for the inclusion of the cone $\mathcal{T}$-point.

For a $\mathcal{T}$-functor $p : \mathcal{K} \longrightarrow \mathcal{C}$, we then let

$$\mathcal{C}^{(p,\mathcal{T})/} := *_{\mathcal{T}} \times_{\sigma_p, \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K},\mathcal{C})} \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K}^{\underline{\triangleright}}, \mathcal{C})\,, \qquad \mathcal{C}^{/(p,\mathcal{T})} := *_{\mathcal{T}} \times_{\sigma_p, \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K},\mathcal{C})} \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K}^{\underline{\triangleleft}}, \mathcal{C})$$

denote the *slice* $\mathcal{T}$-∞-categories.

We will also need in a few places the following smaller model for slicing over and under a $\mathcal{T}$-object.

2.3. **Definition.** Let $\mathcal{C}$ be a $\mathcal{T}$-∞-category. For any object $x \in \mathcal{C}_t$, we write

$$\mathcal{C}^{/\underline{x}} := \mathrm{Ar}_{\mathcal{T}}(\mathcal{C}) \times_{\mathcal{C}} \underline{x}\,, \qquad \mathcal{C}^{\underline{x}/} := \underline{x} \times_{\mathcal{C}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{C})$$

and regard these as $\mathcal{T}^{/t}$-∞-categories via composition of the projection to $\underline{x}$ with the trivial fibration $\underline{x} \xrightarrow{\simeq} (\mathcal{T}^{/t})^{\mathrm{op}}$ ([Sha21, Lem. 12.10]).

2.4. **Observation** ([Sha21, Prop. 4.30])**.** In Definition 2.3, if we write $i_x : \underline{x} \longrightarrow \mathcal{C}_{\underline{t}}$ for the $\mathcal{T}^{/t}$-functor defined by x, then we have canonical equivalences

$$\mathcal{C}^{/\underline{x}} \simeq (\mathcal{C}_{\underline{t}})^{/(i_x, \mathcal{T}^{/t})}\,, \qquad \mathcal{C}^{\underline{x}/} \simeq (\mathcal{C}_{\underline{t}})^{(i_x, \mathcal{T}^{/t})/}$$

of $\mathcal{T}^{/t}$-∞-categories over $\mathcal{C}_{\underline{t}}$. Similarly, for a cocartesian section $\sigma : *_{\mathcal{T}} \longrightarrow \mathcal{C}$, we have canonical equivalences

$$\mathrm{Ar}_{\mathcal{T}}(\mathcal{C}) \times_{\mathcal{C},\sigma} *_{\mathcal{T}} \simeq \mathcal{C}^{/(\sigma,\mathcal{T})}\,, \qquad *_{\mathcal{T}} \times_{\sigma,\mathcal{C}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{C}) \simeq \mathcal{C}^{(\sigma,\mathcal{T})/}$$

of $\mathcal{T}$-∞-categories over $\mathcal{C}$.

We now proceed to our discussion on parametrized colimits; the case of parametrized limits is dual in view of [Sha21, Cor. 5.25] and hence will not be explicitly considered.

2.5. **Definition** ([Sha21, Def. 5.1-2])**.** Let $\mathcal{C}$ be a $\mathcal{T}$-∞-category. A $\mathcal{T}$-functor $\sigma : *_{\mathcal{T}} \longrightarrow \mathcal{C}$ is a $\mathcal{T}$-*initial object* if and only if $\sigma(t) \in \mathcal{C}_t$ is an initial object for all $t \in \mathcal{T}$. A $\mathcal{T}$-functor $\overline{p} : \mathcal{K}^{\underline{\triangleright}} \longrightarrow \mathcal{C}$ is then a $\mathcal{T}$-*colimit diagram* if and only if the $\mathcal{T}$-functor

$$(\mathrm{id}, \sigma_{\overline{p}}) : *_{\mathcal{T}} \longrightarrow \mathcal{C}^{(p,\mathcal{T})/} = *_{\mathcal{T}} \times_{\sigma_p, \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K},\mathcal{C})} \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K}^{\underline{\triangleright}}, \mathcal{C})$$

is a $\mathcal{T}$-initial object. Lastly, we say that a $\mathcal{T}$-functor $p : \mathcal{K} \longrightarrow \mathcal{C}$ *admits a* $\mathcal{T}$-*colimit* if p admits an extension to a $\mathcal{T}$-colimit diagram $\overline{p}$, and we then write $\mathrm{colim}^{\mathcal{T}}_{\mathcal{K}} p = \overline{p}|_v$. If $\mathcal{T}$ moreover has a terminal object t, we will also identify the cocartesian section $\mathrm{colim}^{\mathcal{T}}_{\mathcal{K}} p$ with its value at t.[14]

2.6. **Notation.** Let $p : \mathcal{K} \longrightarrow \mathcal{C}$ be a $\mathcal{T}$-functor and let $\delta : \mathcal{C} \longrightarrow \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K}, \mathcal{C})$ be the constant $\mathcal{T}$-functor. We then write

$$\underline{\mathrm{colim}}^{\mathcal{T}}_{\mathcal{K}} : \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K}, \mathcal{C}) \dashrightarrow \mathcal{C}$$

for the partially-defined[15] $\mathcal{T}$-left adjoint of δ.

The next observation is the trivial case of [Sha21, Cor. 9.16] where we let $\mathcal{D} = \mathcal{T}^{\mathrm{op}}$ there.

2.7. **Observation.** For a $\mathcal{T}$-functor $p : \mathcal{K} \longrightarrow \mathcal{C}$, $\underline{\mathrm{colim}}^{\mathcal{T}}_{\mathcal{K}}$ is defined on an object $p : \mathcal{K}_{\underline{t}} \longrightarrow \mathcal{C}_{\underline{t}}$ in the fiber $\underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K}, \mathcal{C})_t \simeq \mathrm{Fun}_{\mathcal{T}^{/t}}(\mathcal{K}_{\underline{t}}, \mathcal{C}_{\underline{t}})$ if and only if p admits a $\mathcal{T}^{/t}$-colimit, in which case $\underline{\mathrm{colim}}^{\mathcal{T}}_{\mathcal{K}} p \simeq (\mathrm{colim}^{\mathcal{T}^{/t}}_{\mathcal{K}_{\underline{t}}} p)(t)$. In particular, if for each $t \in \mathcal{T}$ the parametrized fiber $\mathcal{C}_{\underline{t}}$ admits all $\mathcal{K}_{\underline{t}}$-indexed $\mathcal{T}^{/t}$-colimits, then $\underline{\mathrm{colim}}^{\mathcal{T}}_{\mathcal{K}}$ is defined on its entire domain.

Passing to cocartesian sections, we then see that

$$\mathrm{colim}^{\mathcal{T}}_{\mathcal{K}} : \mathrm{Fun}_{\mathcal{T}}(\mathcal{K}, \mathcal{C}) \dashrightarrow \mathrm{Fun}_{\mathcal{T}}(*_{\mathcal{T}}, \mathcal{C})$$

is a partial left adjoint to the functor given by precomposing with the structure map of $\mathcal{K}$, and $\mathrm{colim}^{\mathcal{T}}_{\mathcal{K}}$ is defined on its entire domain if $\underline{\mathrm{colim}}^{\mathcal{T}}_{\mathcal{K}}$ is (but possibly not conversely).

This observation already highlights the need to systematically distinguish between $\mathcal{T}$-colimits in $\mathcal{C}$ and $\mathcal{T}^{/t}$-colimits in the parametrized fibers $\mathcal{C}_{\underline{t}}$. We do this as follows:

2.8. **Definition.** Let $\mathcal{C}$ be a $\mathcal{T}$-∞-category.

(1) $\mathcal{C}$ *strongly admits* all $\mathcal{T}$-colimits, i.e., is $\mathcal{T}$-*cocomplete* [Sha21, Def. 5.13], if for each $t \in \mathcal{T}$, $\mathcal{C}_{\underline{t}}$ admits all $\mathcal{T}^{/t}$-colimits.
(2) If $\mathcal{C}$ and $\mathcal{D}$ are $\mathcal{T}$-cocomplete $\mathcal{T}$-∞-categories, then a $\mathcal{T}$-functor $F : \mathcal{C} \longrightarrow \mathcal{D}$ *strongly preserves* all $\mathcal{T}$-colimits if for each $t \in \mathcal{T}$, $F_{\underline{t}} : \mathcal{C}_{\underline{t}} \longrightarrow \mathcal{D}_{\underline{t}}$ preserves all $\mathcal{T}^{/t}$-colimits [Sha21, Def. 11.2].

[14]If $t \in \mathcal{T}^{\mathrm{op}}$ is an initial object, then cocartesian sections are uniquely specified by their value at t.

[15]For a $\mathcal{T}$-functor $R : \mathcal{C} \longrightarrow \mathcal{D}$, the domain of its partial $\mathcal{T}$-left adjoint L is the largest full $\mathcal{T}$-subcategory $\mathcal{D}_0 \subset \mathcal{D}$ for which L_t is a partial left adjoint to R_t for all $t \in \mathcal{T}$ and $f^* L_t \xrightarrow{\simeq} L_s f^*$ for all $(f : s \longrightarrow t) \in \mathcal{T}$.

More generally, if we have a collection $\mathcal{K} = \{\mathcal{K}_t : t \in \mathcal{T}\}$ where $\mathcal{K}_t$ is a class of small $\mathcal{T}^{/t}$-∞-categories such that for each morphism $f : s \longrightarrow t$ in $\mathcal{T}$, $f^*(\mathcal{K}_t) \subset \mathcal{K}_s$, then we have analogous notions of strongly admitting and preserving $\mathcal{K}$-indexed $\mathcal{T}$-colimits. We will typically leave the collection $\{\mathcal{K}_t\}$ implicit when referring to $\mathcal{K}$. Abusing notation, we will also let $\mathcal{K}$ refer to the class of $\mathcal{T}$-∞-categories $\mathcal{K}$ such that $\mathcal{K}_{\underline{t}} \in \mathcal{K}_t$ for all $t \in \mathcal{T}$.

2.9. **Remark.** In this paper, all $\mathcal{T}$-colimits will be indexed by small $\mathcal{T}$-∞-categories, and we will typically suppress the adjective 'small' in this context (as was already done in Definition 2.8).

We next review the theory of $\mathcal{T}$-left Kan extensions along fully faithful $\mathcal{T}$-functors. We first need an auxiliary construction.

2.10. **Remark.** Let $\mathcal{C}$ be a $\mathcal{T}$-∞-category. By definition, the $\mathcal{T}$-right cone $\mathcal{C}^{\underline{\triangleright}}$ has a universal mapping property with respect to maps going *in*. In the following we will also need a universal mapping property of $\mathcal{C}^{\underline{\triangleright}}$ for maps going *out*. Namely, by [Sha21, Lem. 4.5] we have a homotopy pushout square of $\mathcal{T}$-∞-categories

$$\begin{array}{ccc} \mathcal{C} \times \{1\} & \hookrightarrow & \mathcal{C} \times \Delta^1 \\ \downarrow{\scriptstyle p} & & \downarrow{\scriptstyle f} \\ *_{\mathcal{T}} & \xhookrightarrow{v} & \mathcal{C}^{\underline{\triangleright}} \end{array}$$

where f is defined as the adjoint to $(\mathrm{id}_{\mathcal{C}}, p)$.

Now suppose that $\sigma : *_{\mathcal{T}} \longrightarrow \mathcal{C}$ is a $\mathcal{T}$-final object. Then we may construct a homotopy $h : \mathcal{C} \times \Delta^1 \longrightarrow \mathcal{C}$ from $\mathrm{id}_{\mathcal{C}}$ to σ, which yields a $\mathcal{T}$-functor

$$h' : \mathcal{C}^{\underline{\triangleright}} \longrightarrow \mathcal{C}$$

such that $h'|_{\mathcal{C}} = \mathrm{id}_{\mathcal{C}}$ and $h'|_v = \sigma$. Moreover, if one considers the bifibration (cf. [Sha21, Lem. 4.8])

$$(f, g) : \mathrm{Fun}_{\mathcal{T}}(\mathcal{C}^{\underline{\triangleright}}, \mathcal{C}) \longrightarrow \mathrm{Fun}_{\mathcal{T}}(\mathcal{C}, \mathcal{C}) \times \mathrm{Fun}_{\mathcal{T}}(*_{\mathcal{T}}, \mathcal{C})$$

then h' is obtained by taking a f-cartesian lift with target $[\mathcal{C}^{\underline{\triangleright}} \xrightarrow{\overline{p}} *_{\mathcal{T}} \xrightarrow{\sigma} \mathcal{C}]$ in $\mathrm{Fun}_{\mathcal{T}}(\mathcal{C}^{\underline{\triangleright}}, \mathcal{C})$ over the edge $\mathrm{id}_{\mathcal{C}} \longrightarrow \sigma \circ p$ in $\mathrm{Fun}_{\mathcal{T}}(\mathcal{C}, \mathcal{C})$ specified by h.

2.11. **Construction.** Let $\mathcal{D}$ be a $\mathcal{T}$-∞-category and let $x \in \mathcal{D}_t$. We then construct a $\mathcal{T}^{/t}$-functor

$$\theta_x : (\mathcal{D}^{/\underline{x}})^{\underline{\triangleright}} \longrightarrow \mathcal{D}_{\underline{t}}$$

as follows (where the parametrized right cone is formed with respect to the base $\mathcal{T}^{/t}$). First, we adjoint the projection $\mathcal{D}^{/\underline{x}} \longrightarrow \mathrm{Ar}_{\mathcal{T}}(\mathcal{D})$ to obtain a $\mathcal{T}^{/t}$-functor $h_x : \mathcal{D}^{/\underline{x}} \times \Delta^1 \longrightarrow \mathcal{D}_{\underline{t}}$. We then let θ_x be the composite of h_x and the $\mathcal{T}^{/t}$-functor

$$(h', \pi) : (\mathcal{D}^{/\underline{x}})^{\underline{\triangleright}} \longrightarrow \mathcal{D}^{/\underline{x}} \times \Delta^1,$$

where π is the structure map to Δ^1 of the parametrized join and h' is as in Remark 2.10 (note that any choice of cocartesian section $j_x : *_{\mathcal{T}^{/t}} \longrightarrow \mathcal{D}^{/\underline{x}}$ determined by id_x is a $\mathcal{T}^{/t}$-final object).

Now suppose given a $\mathcal{T}$-functor $G : \mathcal{D} \longrightarrow \mathcal{E}$ and a full $\mathcal{T}$-subcategory $\mathcal{C} \subset \mathcal{D}$. We let $F := G|_{\mathcal{C}}$, and for any $x \in \mathcal{D}_t$ we let $\mathcal{C}^{/\underline{x}} := \mathcal{C} \times_{\mathcal{D}} \mathcal{D}^{/\underline{x}}$. We then write

$$G^x : (\mathcal{C}^{/\underline{x}})^{\underline{\triangleright}} \longrightarrow (\mathcal{D}^{/\underline{x}})^{\underline{\triangleright}} \xrightarrow{\theta_x} \mathcal{D}_{\underline{t}} \xrightarrow{G_{\underline{t}}} \mathcal{E}_{\underline{t}}$$

for the composite $\mathcal{T}^{/t}$-functor. Note that $G^x|_{\mathcal{C}^{/\underline{x}}}$ factors as $\mathcal{C}^{/\underline{x}} \longrightarrow \mathcal{C}_{\underline{t}} \xrightarrow{F_{\underline{t}}} \mathcal{E}_{\underline{t}}$; we write F^x for this $\mathcal{T}^{/t}$-functor.

The following is a simplification of [Sha21, Def. 10.1] in which we have chosen the datum of the natural transformation η present there to be the identity, which allows us to dispense with the auxiliary construction of $G'' : (\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{D})) \star_{\mathcal{D}} \mathcal{D} \longrightarrow \mathcal{E}$ in that definition.

2.12. **Definition.** Let $\mathcal{D}$ be a $\mathcal{T}$-∞-category and $\mathcal{C} \subset \mathcal{D}$ a full $\mathcal{T}$-subcategory. We say that a $\mathcal{T}$-functor $G : \mathcal{D} \longrightarrow \mathcal{E}$ is a $\mathcal{T}$-*left Kan extension* of its restriction $F = G|_{\mathcal{C}}$ if for all $x \in \mathcal{D}_t$, the $\mathcal{T}^{/t}$-functor G^x of Construction 2.11 is a $\mathcal{T}^{/t}$-colimit diagram.

A $\mathcal{T}$-functor $F : \mathcal{C} \longrightarrow \mathcal{E}$ then *admits a* $\mathcal{T}$-*left Kan extension to* $\mathcal{D}$ if there exists such a G, and we say that $\{F^x\}_{x \in \mathcal{D}}$ constitutes the set of *relevant diagrams* for the extension problem.

The author proved the following existence and uniqueness theorem for $\mathcal{T}$-left Kan extensions as [Sha21, Thm. 10.3], [Sha21, Thm. 10.5], and [Sha21, Prop. 10.6].

2.13. **Theorem.** *Let $\mathcal{D}$ be a $\mathcal{T}$-∞-category and $\mathcal{C} \subset \mathcal{D}$ a full $\mathcal{T}$-subcategory (with inclusion $\mathcal{T}$-functor ϕ).*

(1) A $\mathcal{T}$-functor $F : \mathcal{C} \longrightarrow \mathcal{E}$ admits a $\mathcal{T}$-left Kan extension G over $\mathcal{D}$ if and only if all the relevant diagrams for F admit parametrized colimits. Moreover, G is then uniquely specified up to contractible choice.

(2) The partial $\mathcal{T}$-left adjoint $\phi_!$ to the restriction $\mathcal{T}$-functor $\phi^* : \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{D}, \mathcal{E}) \longrightarrow \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{C}, \mathcal{E})$ is defined on all $F : \mathcal{C}_{\underline{t}} \longrightarrow \mathcal{E}_{\underline{t}}$ that admit a $\mathcal{T}^{/t}$-left Kan extension G, in which case $\phi_! F \simeq G$. In particular, $\phi_!$ is defined on its entire domain if for every $x \in \mathcal{D}_t$, the parametrized fiber $\mathcal{E}_{\underline{t}}$ admits all $\mathcal{C}^{/\underline{x}}$-indexed $\mathcal{T}^{/t}$-colimits.

In fact, constructing $\mathcal{T}$-left Kan extensions along fully faithful $\mathcal{T}$-functors suffices to handle the general case:

2.14. **Remark.** Let $\phi : \mathcal{C} \longrightarrow \mathcal{D}$ be a $\mathcal{T}$-functor and let $\pi : \mathcal{M} \longrightarrow \Delta^1 \times \mathcal{T}^{\mathrm{op}}$ be a cocartesian fibration classified by ϕ (so $\mathcal{M}$ is a $\mathcal{T}$-∞-category and $\mathcal{C} \simeq \mathcal{M}_0 \subset \mathcal{M}$ is the inclusion of a full $\mathcal{T}$-subcategory). Suppose that we have a $\mathcal{T}$-functor $\overline{G} : \mathcal{M} \longrightarrow \mathcal{E}$ that is a $\mathcal{T}$-left Kan extension of its restriction $F = \overline{G}|_{\mathcal{C}}$. Let $G = \overline{G}|_{\mathcal{D}}$. We then may construct a natural transformation $\eta : F \Rightarrow \phi^* G$ such that η exhibits G as the $\mathcal{T}$-left Kan extension of F along ϕ in the sense of [Sha21, Def. 10.1]. Indeed, consider the trivial fibration[16]

$$p = (\mathrm{ev}_0, \pi) : \mathrm{Ar}_{\mathcal{T}}^{cocart}(\mathcal{M}) \longrightarrow \mathcal{M} \times_{\Delta^1} \mathrm{Ar}(\Delta^1)$$

and let σ be a section that restricts to the identity on $\mathcal{M}$, given by a choice of dotted lift in the diagram

$$\begin{array}{ccc} \mathcal{M} & \xhookrightarrow{\iota} & \mathrm{Ar}_{\mathcal{T}}^{cocart}(\mathcal{M}) \\ \big\downarrow \iota & \overset{\sigma}{\nearrow} & \simeq \big\downarrow p \\ \mathcal{M} \times_{\Delta^1} \mathrm{Ar}(\Delta^1) & \xrightarrow{=} & \mathcal{M} \times_{\Delta^1} \mathrm{Ar}(\Delta^1) \end{array}$$

where ι generically denotes the identity section. Then let

$$\eta : \mathcal{C} \times \Delta^1 = \mathcal{C} \times \{[0=0] \to [0 \to 1]\} \subset \mathcal{M} \times_{\Delta^1} \mathrm{Ar}(\Delta^1) \xrightarrow{\sigma} \mathrm{Ar}_{\mathcal{T}}^{cocart}(\mathcal{M}) \xrightarrow{\mathrm{ev}_1} \mathcal{M} \xrightarrow{\overline{G}} \mathcal{E}$$

and note that $\eta|_{\mathcal{C} \times \{0\}} = F$ and $\eta|_{\mathcal{C} \times \{1\}} = G \circ \phi$. The assertion that $G \simeq \phi_! F$ then follows by examining the pointwise formula defining a $\mathcal{T}$-left Kan extension.

3. Parametrized factorization systems

Our goal in this section is to prove a theorem about parametrized factorization systems (Theorem 3.6) that will allow us to prove the universal property of the free $\mathcal{T}$-cocartesian fibration (Example 3.8) and subsequently that of the $\mathcal{O}$-monoidal envelope for a $\mathcal{T}$-∞-operad $\mathcal{O}$ in [NS].

3.1. **Definition.** Let $\mathcal{C}$ be a $\mathcal{T}$-∞-category. Then a $\mathcal{T}$-*factorization system* on $\mathcal{C}$ is the data of a factorization system $(\mathscr{L}_t, \mathscr{R}_t)$ on the fiber $\mathcal{C}_t$ for every $t \in \mathcal{T}$, subject to the condition that for every morphism $\alpha : s \longrightarrow t$ in $\mathcal{T}$, the restriction functor $\alpha^* : \mathcal{C}_t \longrightarrow \mathcal{C}_s$ sends $(\mathscr{L}_t, \mathscr{R}_t)$ into $(\mathscr{L}_s, \mathscr{R}_s)$.

3.2. **Remark.** In Definition 3.1, we could instead formulate the condition of compatibility of the fiberwise factorization systems with restriction in the following way. Let p denote the structure map of $\mathcal{C}$ and consider the collection of commutative squares in $\mathcal{C}$

$$\begin{array}{ccc} x & \xrightarrow{\alpha_x} & x' \\ f \big\downarrow & & \big\downarrow f' \\ y & \xrightarrow{\alpha_y} & y' \end{array}$$

such that f resp. f' lies in the fiber $\mathcal{C}_t$ resp. $\mathcal{C}_{t'}$, $p(\alpha_x) = p(\alpha_y)$, and α_x, α_y are p-cocartesian edges. Then we must have that if f is in $\mathscr{L}_t$ resp. $\mathscr{R}_t$, then f' is in $\mathscr{L}_{t'}$ resp. $\mathscr{R}_{t'}$.

3.3. **Definition.** Let $\mathcal{C}$ be a $\mathcal{T}$-∞-category with structure map p. Given a $\mathcal{T}$-factorization system $(\mathscr{L}_t, \mathscr{R}_t)_{t \in \mathcal{T}}$ on $\mathcal{C}$, let $\mathscr{L}$ be the collection of edges $e : x \to y$ in $\mathcal{C}$ such that for any factorization $x \xrightarrow{e'} x' \xrightarrow{f} y$ of e by a p-cocartesian edge e' and a fiberwise edge f, f is in $\mathscr{L}_{p(y)}$. Let $\mathscr{R}$ be the closure of the union of the $\mathscr{R}_t$ under equivalences in $\mathcal{C}$.

[16] Cf. [Sha21, Lem. 2.23] applied to π and restrict arrows to be $\mathcal{T}$-fiberwise.

We have the following variant of [Lur17, Prop. 2.1.2.5].

3.4. **Lemma.** *$(\mathscr{L},\mathscr{R})$ is a factorization system on $\mathcal{C}$.*

Proof. We check the three conditions of a factorization system in turn.

(1) Using the stability of the classes $\{\mathscr{L}_t\}$ and $\{\mathscr{R}_t\}$ along with the p-cocartesian edges under retracts, we see that $\mathscr{L}$ and $\mathscr{R}$ are closed under retracts.
(2) Given an edge $e : x \to y$ in $\mathcal{C}$, factor e as $x \xrightarrow{e'} x' \xrightarrow{f} y$ for e' p-cocartesian and f in the fiber $\mathcal{C}_{p(y)}$. Using the factorization system $(\mathscr{L}_{p(y)},\mathscr{R}_{p(y)})$ on $\mathcal{C}_{p(y)}$, factor f as $x' \xrightarrow{f'} x'' \xrightarrow{f''} y$ where $f' \in \mathscr{L}_{p(y)}$ and $f'' \in \mathscr{R}_{p(y)}$. Then $x \xrightarrow{f'\circ e'} x'' \xrightarrow{f''} y$ is our desired factorization of e.
(3) Suppose we have a commutative square

$$\begin{array}{ccc} w & \longrightarrow & y \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle g} \\ x & \longrightarrow & z \end{array}$$

with $f \in \mathscr{L}$ and $g \in \mathscr{R}$; we want to produce an essentially unique filler $x \longrightarrow y$. Without loss of generality, we may suppose $p(y) = p(z)$ and $g \in \mathscr{R}_{p(y)}$. Choosing p-cocartesian edges we may factor the square as

$$\begin{array}{ccccccc} w & \longrightarrow & w' & \longrightarrow & w'' & \longrightarrow & y \\ & \searrow^{f} & \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f''} & \overset{h}{\nearrow} & \downarrow{\scriptstyle g} \\ & & x & \xrightarrow{\alpha} & x' & \longrightarrow & z \end{array}$$

where the edges which 'add a prime' are p-cocartesian, and vertical edges along with the rightmost square lie in a fiber. By definition, $f' \in \mathscr{L}_{p(x)}$, and since the $(\mathscr{L}_t,\mathscr{R}_t)_{t\in\mathcal{T}}$ constitute a $\mathcal{T}$-factorization system on $\mathcal{C}$, $f'' \in \mathscr{L}_{p(y)}$. Then we have an essentially unique filler h, and $h \circ \alpha : x \to y$ is our desired filler.

□

3.5. **Proposition.** *Suppose $\mathcal{D}$ is a $\mathcal{T}$-∞-category and $(\mathscr{L}_t,\mathscr{R}_t)_{t\in\mathcal{T}}$ is a $\mathcal{T}$-factorization system on $\mathcal{D}$. Let $(\mathscr{L},\mathscr{R})$ be the induced factorization system on $\mathcal{D}$ of Definition 3.3.*

(1) Let $\mathrm{Ar}^L_{\mathcal{T}}(\mathcal{D})$ resp. $\mathrm{Ar}^L(\mathcal{D})$ denote the full subcategory of $\mathrm{Ar}_{\mathcal{T}}(\mathcal{D})$ resp. $\mathrm{Ar}(\mathcal{D})$ on the morphisms in $\mathscr{L}$. Then the source map

$$\mathrm{ev}_0 : \mathrm{Ar}^L_{\mathcal{T}}(\mathcal{D}) \longrightarrow \mathcal{D}$$

is a $\mathcal{T}$-cartesian fibration of $\mathcal{T}$-∞-categories, and the source map

$$\mathrm{ev}_0 : \mathrm{Ar}^L(\mathcal{D}) \longrightarrow \mathcal{D}$$

is a cartesian fibration (where here the domain is not generally a $\mathcal{T}$-∞-category).

(2) Let $\mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D})$ denote the full subcategory of $\mathrm{Ar}_{\mathcal{T}}(\mathcal{D})$ on the morphisms in $\mathscr{R}$. Suppose that $p : \mathcal{C} \longrightarrow \mathcal{D}$ is a $\mathcal{T}$-fibration which admits p-cocartesian lifts over all edges in $\mathscr{L}$. Then the target map

$$\mathrm{ev}_1 : \mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}) \longrightarrow \mathcal{D}$$

is a $\mathcal{T}$-cocartesian fibration.

Proof. (1): For the first assertion, since we have the factorization system $(\mathscr{L}_t,\mathscr{R}_t)$ on the fibers $\mathcal{D}_t$ for all $t \in \mathcal{T}$, ev_0 is fiberwise a cartesian fibration, with an edge in $\mathrm{Ar}^{L_t}(\mathcal{D}_t) = \mathrm{Ar}^L_{\mathcal{T}}(\mathcal{D})_t$

$$\begin{array}{ccc} x_0 & \xrightarrow{\alpha} & y_0 \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle \beta} \\ x_1 & \xrightarrow{g} & y_1 \end{array}$$

$(\mathrm{ev}_0)_t$-cartesian if and only if g is in $\mathscr{R}_t$. Since the factorization systems in the fibers are compatible with restriction, it follows that ev_0 is in addition $\mathcal{T}$-cartesian.

For the second assertion, repeat the argument with the factorization system $(\mathscr{L},\mathscr{R})$ on $\mathcal{D}$ itself.

(2): The argument is dual to (1), except that now the ev_1-cocartesian edges are given by

$$(\alpha, (f, g)) : (c_0, x_0 \to y_0) \longrightarrow (c_1, x_1 \to y_1)$$

with $f \in \mathscr{L}$ and α a p-cocartesian edge. $\square$

3.6. **Theorem.** *Suppose we are in the setup of Proposition 3.5(2) so that we have a $\mathcal{T}$-fibration $p : \mathcal{C} \longrightarrow \mathcal{D}$ that admits p-cocartesian lifts over all edges in $\mathscr{L}$.*

(1) For every cocartesian fibration $q : \mathcal{E} \longrightarrow \mathcal{D}$, restriction along the inclusion $i : \mathcal{C} \longrightarrow \mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D})$ yields a trivial fibration

$$i^* : \mathrm{Fun}^{cocart}_{/\mathcal{D}}(\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}), \mathcal{E}) \longrightarrow \mathrm{Fun}^L_{/\mathcal{D}}(\mathcal{C}, \mathcal{E})$$

where we define

$$\mathrm{Fun}^{cocart}_{/\mathcal{D}}(\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}), \mathcal{E}) := \mathrm{Fun}_{/\mathcal{D}}({}_\natural(\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D})), {}_\natural\mathcal{E}),$$
$$\mathrm{Fun}^L_{/\mathcal{D}}(\mathcal{C}, \mathcal{E}) := \mathrm{Fun}_{/\mathcal{D}}((\mathcal{C}, M), {}_\natural\mathcal{E}),$$

and the marked edges M in $\mathcal{C}$ are the p-cocartesian edges of $\mathcal{C}$ over $\mathscr{L}$.[17] *In other words,*

$$i : (\mathcal{C}, M) \longrightarrow {}_\natural(\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}))$$

is a cocartesian equivalence in $\mathbf{sSet}^+_{/\mathcal{D}}$.

(2) Let M' denote the ev_1-cocartesian edges in $\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D})$ over $\mathscr{L}$ and define

$$\mathrm{Fun}^L_{/\mathcal{D}}(\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}), \mathcal{E}) := \mathrm{Fun}_{/\mathcal{D}}((\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}), M'), {}_\natural\mathcal{E}).$$

Then we have an adjunction

$$i_! : \mathrm{Fun}^L_{/\mathcal{D}}(\mathcal{C}, \mathcal{E}) \rightleftarrows \mathrm{Fun}^L_{/\mathcal{D}}(\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}), \mathcal{E}) : i^*$$

where $i_!$ is the fully faithful inclusion of the full subcategory $\mathrm{Fun}^{cocart}_{/\mathcal{D}}(\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}), \mathcal{E})$ under the equivalence of (1).

Proof. (1): Given a monomorphism $A \longrightarrow B$ of simplicial sets, we need to solve the lifting problem

$$\begin{array}{ccc} A^\flat \times {}_\natural(\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D})) \bigcup_{A^\flat \times (\mathcal{C}, M)} B^\flat \times (\mathcal{C}, M) & \longrightarrow & {}_\natural\mathcal{E} \\ \downarrow & \nearrow & \downarrow q \\ B^\flat \times {}_\natural(\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D})) & \longrightarrow & \mathcal{D}^\sharp. \end{array}$$

Let us suppress markings for clarity. We can factor this square as

$$\begin{array}{ccccccc} A \times (\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D})) \bigcup_{A \times \mathcal{C}} B \times \mathcal{C} & \longrightarrow & \mathcal{E} & \xrightarrow{\iota} & \mathrm{Ar}^{cocart}_{\mathcal{T}}(\mathcal{E}) & \xrightarrow{\mathrm{ev}_1} & \mathcal{E} \\ \downarrow & & & \nearrow & \downarrow \simeq & & \downarrow q \\ B \times (\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D})) & & \xrightarrow{\lambda} & & \mathcal{E} \times_{\mathcal{D}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{D}) & \xrightarrow{\mathrm{ev}_1} & \mathcal{D} \end{array}$$

where the map λ is given by

$$B \times (\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D})) \longrightarrow B \times \mathcal{C} \longrightarrow \mathcal{E},$$
$$B \times (\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D})) \longrightarrow B \times \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}) \longrightarrow \mathrm{Ar}_{\mathcal{T}}(\mathcal{D}),$$

and the map $\mathrm{Ar}^{cocart}_{\mathcal{T}}(\mathcal{E}) \longrightarrow \mathcal{E} \times_{\mathcal{D}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{D})$ is a pullback of the known trivial fibration $\mathrm{Ar}^{cocart}(\mathcal{E}) \longrightarrow \mathcal{E} \times_{\mathcal{D}} \mathrm{Ar}(\mathcal{D})$ of [Sha21, Lem. 2.23] by the identity section $\mathcal{T} \longrightarrow \mathrm{Ar}(\mathcal{T})$, hence is a trivial fibration. Therefore, the dotted arrow exists, and postcomposing by ev_1 yields the desired lift.

(2): We need to show that $\mathrm{Fun}^{cocart}_{/\mathcal{D}}(\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}), \mathcal{E}) \subset \mathrm{Fun}^L_{/\mathcal{D}}(\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}), \mathcal{E})$ is a coreflective subcategory. For this, it suffices to show that for every object $F \in \mathrm{Fun}^L_{/\mathcal{D}}(\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}), \mathcal{E})$, there exists a

[17] Note that objects of $\mathrm{Fun}^L_{/\mathcal{D}}(\mathcal{C}, \mathcal{E})$ are necessarily $\mathcal{T}$-functors.

colocalization $\epsilon_F : G \longrightarrow F$ relative to $\mathrm{Fun}^{cocart}_{/\mathcal{D}}(\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}), \mathcal{E})$ in the sense of [Lur09, Def. 5.2.7.6] (after taking opposites there). We will construct this explicitly as follows. First define a homotopy

$$H : \Delta^1 \times \mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}) \longrightarrow \mathcal{E} \times_{\mathcal{D}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{D})$$

between the functors

$$H_0 = (F \circ i, \subset) : \mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}) \longrightarrow \mathcal{E} \times_{\mathcal{D}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{D}), \qquad (c, x \to y) \mapsto (F(c, x = x), x \to y),$$
$$H_1 = (\mathrm{id}, \iota_{\mathcal{D}} q) \circ F : \mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}) \longrightarrow \mathcal{E} \longrightarrow \mathcal{E} \times_{\mathcal{D}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{D}), \qquad (c, x \to y) \mapsto (F(c, x \to y), y = y)$$

in the following way: let $\min, \max : \Delta^1 \times \Delta^1 \longrightarrow \Delta^1$ be the min and max maps, form the functors

$$F' = \mathrm{Ar}_{\mathcal{T}}(F) \circ (\iota, \min^*) : \mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}) \longrightarrow \mathrm{Ar}_{\mathcal{T}}(\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D})) \longrightarrow \mathrm{Ar}_{\mathcal{T}}(\mathcal{E}),$$
$$G' = \max^* \circ \mathrm{pr}_2 : \mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}) \longrightarrow \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}) \longrightarrow \mathrm{Ar}_{\mathcal{T}}(\mathrm{Ar}_{\mathcal{T}}(\mathcal{D})),$$

and let H be the adjoint of the resulting map

$$(F', G') : \mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}) \longrightarrow \mathrm{Ar}_{\mathcal{T}}(\mathcal{E} \times_{\mathcal{D}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{D})).$$

We then place H into the commutative diagram

$$\begin{array}{ccccccc}
\{1\} \times \mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}) & \xrightarrow{F} \mathcal{E} \xrightarrow{\iota} & \mathrm{Ar}^{cocart}_{\mathcal{T}}(\mathcal{E}) & \xrightarrow{\mathrm{ev}_1} & \mathcal{E} \\
\downarrow & \overset{\epsilon'_F}{\nearrow} & \downarrow \simeq & & \downarrow q \\
\Delta^1 \times \mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}) & \xrightarrow{H} & \mathcal{E} \times_{\mathcal{D}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{D}) & \xrightarrow{\mathrm{ev}_1} & \mathcal{D}.
\end{array}$$

Let ϵ'_F be any filler, and define $\epsilon_F = \mathrm{ev}_1 \circ \epsilon'_F$. Note that $\epsilon_F(0) \simeq i_! i^* F$ and $\epsilon_F(1) = F$. We now make the following simple observations, whose verification we leave to the reader:

(1) For every natural transformation $\theta : F \longrightarrow G$, the square

$$\begin{array}{ccc}
i_! i^* F & \xrightarrow{i_! i^* \theta} & i_! i^* G \\
\downarrow \epsilon_F & & \downarrow \epsilon_G \\
F & \xrightarrow{\theta} & G
\end{array}$$

is homotopy commutative.

(2) $i_! i^* \epsilon_F$ is an equivalence.

(3) $\epsilon_{i_! i^* F}$ is an equivalence.

Examining the part of the proof of [Lur09, Prop. 5.2.7.4] that establishes the implication 5.2.7.4(3) $\Rightarrow$ 5.2.7.4(1), we conclude that ϵ_F is indeed a colocalization, so we are done by [Lur09, Prop. 5.2.7.8]. ☐

3.7. **Remark.** Replacing the $\mathcal{T}$-factorization system $(\mathscr{L}_t, \mathscr{R}_t)_{t \in \mathcal{T}}$ by the factorization system $(\mathscr{L}, \mathscr{R})$ on $\mathcal{D}$ (Lemma 3.4), note that since edges in $\mathscr{R}$ map down to equivalences in $\mathcal{T}^{\mathrm{op}}$, we have that $\mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}) \xrightarrow{\simeq} \mathrm{Ar}^R(\mathcal{D})$ where by the latter ∞-category we mean the full subcategory of $\mathrm{Ar}(\mathcal{D})$ on those edges in $\mathscr{R}$. Theorem 3.6 could thus be formulated entirely in 'non-parametrized' terms; this is related to the fact that a $\mathcal{T}$-functor $q : \mathcal{E} \longrightarrow \mathcal{D}$ is a $\mathcal{T}$-cocartesian fibration if and only if it is a cocartesian fibration [Sha21, Rem. 7.4]. In this form, Ayala–Mazel-Gee–Rozenblyum have also articulated Theorem 3.6(1) model-independently in terms of an adjunction of ∞-categories [AMGR17, Prop. B.1].

We end this section by giving two important applications of Theorem 3.6.

3.8. **Example.** Let $(\mathscr{L}_t, \mathscr{R}_t)_{t \in \mathcal{T}}$ be the $\mathcal{T}$-factorization system given by letting $\mathscr{L}_t$ be the equivalences and $\mathscr{R}_t$ be all morphisms for every $t \in \mathcal{T}$. Then $\mathrm{Ar}^R_{\mathcal{T}}(\mathcal{D}) = \mathrm{Ar}_{\mathcal{T}}(\mathcal{D})$, and $\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{D})$ is the free $\mathcal{T}$-cocartesian fibration on $\mathcal{D}$ ([Sha21, Def. 7.6]). By Theorem 3.6(1), we see that $i : \mathcal{C} \longrightarrow \mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{D})$ has the expected universal property: for every $\mathcal{T}$-cocartesian fibration $\mathcal{E} \longrightarrow \mathcal{D}$,

$$i^* : \mathrm{Fun}^{cocart}_{/\mathcal{D}, \mathcal{T}}(\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{D}), \mathcal{E}) \longrightarrow \mathrm{Fun}_{/\mathcal{D}, \mathcal{T}}(\mathcal{C}, \mathcal{E})$$

is an equivalence. This promotes to an adjunction

$$\mathrm{Fr}^{cocart} \colon (\mathbf{Cat}_{\mathcal{T}})_{/\mathcal{D}} \rightleftarrows (\mathbf{Cat}_{\mathcal{T}})^{cocart}_{/\mathcal{D}} \simeq \mathbf{Cat}_{\mathcal{D}} : \mathrm{U}.$$

When $\mathcal{T} = *$, this recovers [GHN17, Thm. 4.5].

By Theorem 3.6(2), we also have an adjunction

$$i_! \colon \mathrm{Fun}_{/\mathcal{D},\mathcal{T}}(\mathcal{C},\mathcal{E}) \rightleftarrows \mathrm{Fun}_{/\mathcal{D},\mathcal{T}}(\mathcal{C}\times_{\mathcal{D}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{D}),\mathcal{E}) : i^*$$

in which $i_!$ is fully faithful.

3.9. **Example.** Suppose $\mathcal{T} = *$ and consider the inert-active factorization system on an ∞-operad $\mathcal{O}^{\otimes}$. Let $p : \mathcal{C}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ be a fibration of ∞-operads. Then $\mathrm{Env}_{\mathcal{O}}(\mathcal{C})^{\otimes} := \mathcal{C}^{\otimes} \times_{\mathcal{O}^{\otimes}} \mathrm{Ar}^{act}(\mathcal{O}^{\otimes})$ is the $\mathcal{O}$-*monoidal envelope* of $\mathcal{C}^{\otimes}$ [Lur17, Constr. 2.2.4.1], and by Theorem 3.6(1) for any $\mathcal{O}$-monoidal ∞-category $\mathcal{D}^{\otimes}$ we have that

$$\mathrm{Fun}^{\otimes}_{\mathcal{O}}(\mathrm{Env}_{\mathcal{O}}(\mathcal{C}),\mathcal{D}) \xrightarrow{\simeq} \mathbf{Alg}_{\mathcal{C}/\mathcal{O}}(\mathcal{D}).$$

This recovers [Lur17, Prop. 2.2.4.9].

4. Parametrized pairing construction

In this section, we first introduce the concept of a $\mathcal{T}$-*flat fibration* $p : \mathcal{X} \longrightarrow \mathcal{B}$, which will amount to a condition on p that ensures that the pullback functor

$$p^* : (\mathbf{Cat}_{\mathcal{T}})^{/\mathcal{B}} \longrightarrow (\mathbf{Cat}_{\mathcal{T}})^{/\mathcal{X}}$$

admits a right adjoint p_* (Remark 4.10). Given another $\mathcal{T}$-fibration $q : \mathcal{Y} \longrightarrow \mathcal{B}$, we then recall from [Sha21, Constr. 9.1] the $\mathcal{B}$-*relative* $\mathcal{T}$-*pairing construction* $\widetilde{\mathrm{Fun}}_{\mathcal{B},\mathcal{T}}(\mathcal{X},\mathcal{Y})$ (Theorem-Construction 4.2) as a certain $\mathcal{T}$-fibration over $\mathcal{B}$. In our discussion in [Sha21, §9], we only established the properties of the $\mathcal{T}$-pairing construction needed for our application to proving the existence theorem for $\mathcal{T}$-left Kan extensions. We enter into a more systematic discussion here by first proving its base-change property (Proposition 4.5) and then its universal property internal to $\mathcal{T}$-∞-categories (Theorem 4.9), from which it follows that

$$\widetilde{\mathrm{Fun}}_{\mathcal{B},\mathcal{T}}(\mathcal{X},\mathcal{Y}) \simeq p_* p^*(\mathcal{Y} \xrightarrow{q} \mathcal{B})$$

at the level of the underlying ∞-category $(\mathbf{Cat}_{\mathcal{T}})^{/\mathcal{B}}$ of $\mathbf{sSet}^+_{/\natural\mathcal{B}}$.[18] We then apply the $\mathcal{T}$-pairing construction to study $\mathcal{T}$-(co)limits in a $\mathcal{T}$-∞-category of sections (Theorem 4.16). This material will be used in [NS] to understand $\mathcal{T}$-(co)limits in $\mathcal{T}$-∞-categories of $\mathcal{O}$-algebras for a $\mathcal{T}$-∞-operad $\mathcal{O}$.

4.1. **Definition.** Let $p : \mathcal{X} \longrightarrow \mathcal{B}$ be a $\mathcal{T}$-fibration. We say that p is a $\mathcal{T}$-*flat fibration* if for every $t \in \mathcal{T}$, the pullback $p_t : \mathcal{X}_t \longrightarrow \mathcal{B}_t$ is flat.

In what follows, for a $\mathcal{T}$-∞-category $\mathcal{B}$ we let $\mathrm{Ar}^{cocart}(\mathcal{B}) \subset \mathrm{Ar}(\mathcal{B})$ denote the full subcategory on arrows that are cocartesian edges with respect to the structure map to $\mathcal{T}^{\mathrm{op}}$.

4.2. **Theorem-Construction** ([Sha21, Def. 9.1])**.** Let $p : \mathcal{X} \longrightarrow \mathcal{B}$ be a $\mathcal{T}$-flat fibration and consider the span of marked simplicial sets

$$\natural\mathcal{B} \xleftarrow{\mathrm{ev}_0} (\mathrm{Ar}^{cocart}(\mathcal{B}) \times_{\mathrm{ev}_1,\mathcal{B},p} \mathcal{X}, \mathscr{E}) \xrightarrow{\mathrm{pr}_{\mathcal{X}}} \natural\mathcal{X}$$

in which $\mathcal{B}$ and $\mathcal{X}$ are given the cocartesian markings (with respect to the structure maps to $\mathcal{T}^{\mathrm{op}}$), and an edge e in $\mathrm{Ar}^{cocart}(\mathcal{B}) \times_{\mathcal{B}} \mathcal{X}$ is marked if and only if $\mathrm{ev}_0(e)$ is marked and $\mathrm{pr}_{\mathcal{X}}(e)$ is marked. The functor

$$(\mathrm{ev}_0)_*(\mathrm{pr}_{\mathcal{X}})^* : \mathbf{sSet}^+_{/\natural\mathcal{X}} \longrightarrow \mathbf{sSet}^+_{/\natural\mathcal{B}}$$

is then right Quillen with respect to the slice model structures induced from the cocartesian model structure on $\mathbf{sSet}^+_{/\mathcal{T}^{\mathrm{op}}}$. For a $\mathcal{T}$-fibration $q : \mathcal{Y} \longrightarrow \mathcal{B}$, we then define the $\mathcal{T}$-*pairing* of $(\mathcal{X}, p)$ and $(\mathcal{Y}, q)$ to be the $\mathcal{T}$-fibration over $\mathcal{B}$ given by

$$\widetilde{\mathrm{Fun}}_{\mathcal{B},\mathcal{T}}(\mathcal{X},\mathcal{Y}) := (\mathrm{ev}_0)_*(\mathrm{pr}_{\mathcal{X}})^* q^*(\natural\mathcal{Y}),$$

where the marked edges are precisely the cocartesian edges with respect to the structure map to $\mathcal{T}^{\mathrm{op}}$.

Proof. The assertion that $(\mathrm{ev}_0)_*(\mathrm{pr}_{\mathcal{X}})^*$ is right Quillen was proved under the assumption that p is a $\mathcal{T}$-cocartesian or $\mathcal{T}$-cartesian fibration in [Sha21, Thm. 9.3(1)]. However, that assumption was only used in the proof to show that ev_0 is flat. Using our weaker assumption that p is $\mathcal{T}$-flat, this follows instead from Lemma 10.1 applied to the factorization system $(\mathscr{L}, \mathscr{R})$ on $\mathcal{B}$ with $\mathscr{L}$ given by the cocartesian edges and $\mathscr{R}$ given by those edges lying over equivalences in $\mathcal{T}^{\mathrm{op}}$ [Lur09, Ex. 5.2.8.15]. □

[18]We equip $\mathbf{sSet}^+_{/\natural\mathcal{B}}$ with the slice model structure with respect to the cocartesian model structure on $\mathbf{sSet}^+_{/(\mathcal{T}^{\mathrm{op}})^\sharp}$. Since $\natural\mathcal{B} \longrightarrow (\mathcal{T}^{\mathrm{op}})^\sharp$ is fibrant, we may indeed identify the underlying ∞-category as $(\mathbf{Cat}_{\mathcal{T}})^{/\mathcal{B}}$.

4.3. **Recollection.** If $p : \mathcal{X} \longrightarrow \mathcal{B}$ is a $\mathcal{T}$-cartesian fibration and $q : \mathcal{Y} \longrightarrow \mathcal{B}$ is a $\mathcal{T}$-cocartesian fibration, then we showed in [Sha21, Thm. 9.3] that $r : \widetilde{\mathrm{Fun}}_{\mathcal{B},\mathcal{T}}(\mathcal{X}, \mathcal{Y}) \longrightarrow \mathcal{B}$ is a $\mathcal{T}$-cocartesian fibration. Moreover, we may produce $\widetilde{\mathrm{Fun}}_{\mathcal{B},\mathcal{T}}(\mathcal{X}, \mathcal{Y})$ as a marked simplicial set with the r-cocartesian edges marked in the following way: let $\mathscr{E}' \subset (\mathrm{Ar}^{cocart}(\mathcal{B}) \times_{\mathcal{B}} \mathcal{X})_1$ be the minimal collection of edges closed under composition that contains the class $\mathscr{E}$ in Theorem-Construction 4.2 and the ev_0-cartesian edges in $\mathrm{Ar}^{cocart}(\mathcal{B}) \times_{\mathcal{B}} \mathcal{X}$, which are those edges

$$\left(\begin{array}{ccc} b_0 & \longrightarrow & b_1 \\ \downarrow & & \downarrow \\ c_0 & \xrightarrow{f} & c_1 \end{array}, \; x_0 \xrightarrow{g} x_1 \right)$$

such that f is sent to an equivalence in $\mathcal{T}^{\mathrm{op}}$ and g is a p-cartesian edge.[19] Then the span of marked simplicial sets

$$\mathcal{B}^\sharp \xleftarrow{\mathrm{ev}_0} (\mathrm{Ar}^{cocart}(\mathcal{B}) \times_{\mathcal{B}} \mathcal{X}, \mathscr{E}') \xrightarrow{\mathrm{ev}_1} \mathcal{B}^\sharp$$

defines via $(\mathrm{ev}_0)_*(\mathrm{ev}_1)^*(\mathcal{Y}, q\text{-cocart})$ the same underlying simplicial set $\widetilde{\mathrm{Fun}}_{\mathcal{B},\mathcal{T}}(\mathcal{X}, \mathcal{Y})$ as before, but with the r-cocartesian edges marked. Unwinding the definitions, we thus see that $\widetilde{\mathrm{Fun}}_{\mathcal{B},\mathcal{T}}(\mathcal{X}, \mathcal{Y})$ enjoys the following additional functoriality with respect to morphisms in $\mathcal{B}$: for every fiberwise morphism $f : b \longrightarrow b' \in \mathcal{B}_t$, we have a pushforward functor

$$f_! : \mathrm{Fun}_{\mathcal{T}^{/t}}(\mathcal{X}_{\underline{b}}, \mathcal{Y}_{\underline{b}}) \longrightarrow \mathrm{Fun}_{\mathcal{T}^{/t}}(\mathcal{X}_{\underline{b'}}, \mathcal{Y}_{\underline{b'}}), \; F \mapsto f_! \circ F \circ f^*$$

where $f^* : \mathcal{X}_{\underline{b'}} \longrightarrow \mathcal{X}_{\underline{b}}$ and $f_! : \mathcal{Y}_{\underline{b}} \longrightarrow \mathcal{Y}_{\underline{b'}}$ are the $\mathcal{T}^{/t}$-functors encoded by p and q.

We next establish the compatibility of the $\mathcal{T}$-pairing construction with base-change. First, we need a lemma.

4.4. **Lemma.** *Let $f : \mathcal{A} \longrightarrow \mathcal{B}$ be a $\mathcal{T}$-functor. The functor*

$$\psi : \mathrm{Ar}^{cocart}(\mathcal{A}) \longrightarrow \mathcal{A} \times_{f,\mathcal{B},\mathrm{ev}_0} \mathrm{Ar}^{cocart}(\mathcal{B})$$

induced by f is a homotopy equivalence of cartesian fibrations over $\mathcal{A}$ (with respect to ev_0 *on the source and projection to $\mathcal{A}$ on the target).*

Proof. By [Sha21, Lem. 9.2(1)], $\mathrm{ev}_0 : \mathrm{Ar}^{cocart}(\mathcal{A}) \longrightarrow \mathcal{A}$ is a cartesian fibration and an edge e is ev_0-cartesian if and only if the projection of $\mathrm{ev}_1(e)$ to $\mathcal{T}^{\mathrm{op}}$ is an equivalence. It follows that ψ preserves cartesian edges, so to show ψ is a homotopy equivalence it suffices to check that for every $a \in \mathcal{A}$, the map on fibers

$$\psi_a : \underline{a} = \{a\} \times_{\mathcal{A},\mathrm{ev}_0} \mathrm{Ar}^{cocart}(\mathcal{A}) \longrightarrow \underline{f(a)} = \{f(a)\} \times_{\mathcal{B},\mathrm{ev}_0} \mathrm{Ar}^{cocart}(\mathcal{B})$$

is an equivalence of ∞-categories. But if a lies over $t \in T^{\mathrm{op}}$, then the induced projections $\underline{a} \longrightarrow (\mathcal{T}^{/t})^{\mathrm{op}}$ and $\underline{f(a)} \longrightarrow (\mathcal{T}^{/t})^{\mathrm{op}}$ are equivalences (cf. [Sha21, Notn. 2.28]), so ψ_a is an equivalence. □

4.5. **Proposition.** *Let $f : \mathcal{A} \longrightarrow \mathcal{B}$ be a $\mathcal{T}$-functor, let $\mathcal{X} \longrightarrow \mathcal{B}$ be a $\mathcal{T}$-flat fibration, and let $\mathcal{Y} \longrightarrow \mathcal{B}$ be a $\mathcal{T}$-fibration. We have a canonical and natural equivalence of $\mathcal{T}$-fibrations over $\mathcal{A}$*

$$\widetilde{\mathrm{Fun}}_{\mathcal{A},\mathcal{T}}(\mathcal{X} \times_{\mathcal{B}} \mathcal{A}, \mathcal{Y} \times_{\mathcal{B}} \mathcal{A}) \simeq \widetilde{\mathrm{Fun}}_{\mathcal{B},\mathcal{T}}(\mathcal{X}, \mathcal{Y}) \times_{\mathcal{B}} \mathcal{A}.$$

Proof. Consider the morphism of spans

$$\begin{array}{ccccc} & & \mathrm{Ar}^{cocart}(\mathcal{A}) \times_{\mathcal{A}} (\mathcal{A} \times_{\mathcal{B}} \mathcal{X}) & & \\ & \swarrow^{\mathrm{ev}_0} & \downarrow \phi & \searrow^{\mathrm{pr}_{\mathcal{X}}} & \\ \mathcal{A} & \xleftarrow{\mathrm{pr}_{\mathcal{A}}} & \mathcal{A} \times_{\mathcal{B}} \mathrm{Ar}^{cocart}(\mathcal{B}) \times_{\mathcal{B}} \mathcal{X} & \xrightarrow{\mathrm{pr}_{\mathcal{X}}} & \mathcal{X} \end{array}$$

where ϕ is induced by f. Noting that $\mathcal{T}$-flat fibrations are stable under pullback, we see that ϕ induces a comparison functor (after marking as necessary)

$$\Phi : \widetilde{\mathrm{Fun}}_{\mathcal{B},\mathcal{T}}(\mathcal{X}, \mathcal{Y}) \times_{\mathcal{B}} \mathcal{A} \longrightarrow \widetilde{\mathrm{Fun}}_{\mathcal{A},\mathcal{T}}(\mathcal{X} \times_{\mathcal{B}} \mathcal{A}, \mathcal{Y} \times_{\mathcal{B}} \mathcal{A}).$$

By Lemma 4.4, ϕ is a homotopy equivalence. Moreover, the homotopy inverse respects the projection to $\mathcal{X}$, so by the proof of [Sha21, Lem. 2.27], Φ is an equivalence of $\mathcal{T}$-fibrations over $\mathcal{A}$. □

[19] See [Sha21, Lem. 7.5] for a justification as to why we can take p-cartesian edges here as opposed to fiberwise cartesian.

We can use the base-change property of the $\mathcal{T}$-pairing construction explicated in Proposition 4.5 to give a more transparent identification of its parametrized fibers [Sha21, Prop. 9.7].

4.6. **Corollary.** *Let $\mathcal{X} \longrightarrow \mathcal{B}$ be a $\mathcal{T}$-flat fibration and $\mathcal{Y} \longrightarrow \mathcal{B}$ a $\mathcal{T}$-fibration. For every $b \in \mathcal{B}$ over $t \in \mathcal{T}^{op}$, we have an equivalence of $\mathcal{T}^{/t}$-∞-categories*

$$\widetilde{\operatorname{Fun}}_{\mathcal{B},\mathcal{T}}(\mathcal{X},\mathcal{Y})_{\underline{b}} \simeq \underline{\operatorname{Fun}}_{\mathcal{T}^{/t}}(\mathcal{X}_{\underline{b}},\mathcal{Y}_{\underline{b}})$$

Proof. We may invoke Proposition 4.5 to replace $\mathcal{B}$ with $\mathcal{B}_{\underline{t}}$, and invoke Proposition 4.5 again with $\mathcal{A} = \underline{b} \longrightarrow \mathcal{B}$ to reduce to the case $\mathcal{B} = \mathcal{T}$, for which $\widetilde{\operatorname{Fun}}_{\mathcal{T},\mathcal{T}}(-,-) \cong \operatorname{Fun}_{\mathcal{T}}(-,-)$ as marked simplicial sets. □

We next proceed to articulate the universal property of the $\mathcal{T}$-pairing construction (Theorem 4.9) as a partially-defined internal hom for $\mathcal{T}$-fibrations over a fixed base $\mathcal{T}$-∞-category.

4.7. **Notation.** Let $\mathcal{B}$ be a $\mathcal{T}$-∞-category, let $p : \mathcal{X} \longrightarrow \mathcal{B}$, $q : \mathcal{Y} \longrightarrow \mathcal{B}$ be $\mathcal{T}$-fibrations over $\mathcal{B}$, and let $q_\circ : \underline{\operatorname{Fun}}_{\mathcal{T}}(\mathcal{X},\mathcal{Y}) \longrightarrow \underline{\operatorname{Fun}}_{\mathcal{T}}(\mathcal{X},\mathcal{B})$ be the $\mathcal{T}$-functor given by postcomposition by q. We then let

$$\underline{\operatorname{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{X},\mathcal{Y}) := *_{\mathcal{T}} \times_{\sigma_p,\underline{\operatorname{Fun}}_{\mathcal{T}}(\mathcal{X},\mathcal{B}),q_\circ} \underline{\operatorname{Fun}}_{\mathcal{T}}(\mathcal{X},\mathcal{Y})$$

denote the $\mathcal{T}$-∞-category of $\mathcal{T}$-functors $\mathcal{X} \longrightarrow \mathcal{Y}$ over $\mathcal{B}$.

4.8. **Lemma.** *Let $p : \mathcal{X} \longrightarrow \mathcal{B}$ be a $\mathcal{T}$-fibration and consider the span of marked simplicial sets*

$$(\mathcal{T}^{op})^\sharp \xleftarrow{\operatorname{ev}_0} \operatorname{Ar}(\mathcal{T}^{op})^\sharp \times_{\operatorname{ev}_1,(\mathcal{T}^{op})^\sharp} {}_\natural\mathcal{X} \xrightarrow{p \circ \operatorname{pr}_{\mathcal{X}}} {}_\natural\mathcal{B}.$$

For any $\mathcal{T}$-fibration $q : \mathcal{Y} \longrightarrow \mathcal{B}$, we then have an equivalence of $\mathcal{T}$-∞-categories

$$(\operatorname{ev}_0)_*(p \circ \operatorname{pr}_{\mathcal{X}})^*({}_\natural Y) \simeq \underline{\operatorname{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{X},\mathcal{Y})$$

which is an isomorphism at the level of marked simplicial sets.

Proof. By definition, given a map of marked simplicial sets $K \longrightarrow (\mathcal{T}^{op})^\sharp$, we have natural bijections

$$\begin{aligned}\operatorname{Hom}_{/(\mathcal{T}^{op})^\sharp}(K,(\operatorname{ev}_0)_*(p\circ\operatorname{pr}_{\mathcal{X}})^*({}_\natural\mathcal{Y})) &\cong \operatorname{Hom}_{/{}_\natural\mathcal{B}}(K \times_{\mathcal{T}^{op}} \operatorname{Ar}(\mathcal{T}^{op})^\sharp \times_{\mathcal{T}^{op}} {}_\natural\mathcal{X}, {}_\natural\mathcal{Y}) \\ &\cong \operatorname{Hom}_{/(\mathcal{T}^{op})^\sharp}(K \times_{\mathcal{T}^{op}} \operatorname{Ar}(\mathcal{T}^{op})^\sharp \times_{\mathcal{T}^{op}} {}_\natural\mathcal{X}, {}_\natural\mathcal{Y}) \times_{\operatorname{Hom}_{/(\mathcal{T}^{op})^\sharp}(K\times_{\mathcal{T}^{op}}\operatorname{Ar}(\mathcal{T}^{op})^\sharp\times_{\mathcal{T}^{op}}{}_\natural\mathcal{X},{}_\natural\mathcal{B})} \{\phi \circ \operatorname{pr}\}\end{aligned}$$

yielding an isomorphism of marked simplicial sets over $\mathcal{T}^{op}$

$$(\operatorname{ev}_0)_*(p \circ \operatorname{pr}_{\mathcal{X}})^*({}_\natural Y) \cong {}_\natural\underline{\operatorname{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{X},\mathcal{Y}).$$

□

4.9. **Theorem.** *We have a canonical equivalence of $\mathcal{T}$-∞-categories*

$$\underline{\operatorname{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C},\widetilde{\operatorname{Fun}}_{\mathcal{B},\mathcal{T}}(\mathcal{X},\mathcal{Y})) \simeq \underline{\operatorname{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C} \times_{\mathcal{B}} \mathcal{X},\mathcal{Y})$$

natural in $\mathcal{T}$-flat fibrations $p : \mathcal{X} \longrightarrow \mathcal{B}$ and $\mathcal{T}$-fibrations $\mathcal{C},\mathcal{Y} \longrightarrow \mathcal{B}$.

Proof. By Proposition 4.5, we may assume $\mathcal{C} = \mathcal{B}$ without loss of generality. We then adopt essentially the same strategy that we used to show [Sha21, Eqn. 9.12.1] (which is the equivalence when $\mathcal{Y} = \mathcal{B} \times_{\mathcal{T}^{op}} \mathcal{E}$) by considering the diagram of marked simplicial sets

$$\begin{array}{ccccc}\operatorname{Ar}(\mathcal{T}^{op})^\sharp \times_{\mathcal{T}^{op}} {}_\natural\mathcal{X} & \xrightarrow{(j,\operatorname{id})} & (\operatorname{Ar}^{cocart}(\mathcal{B}) \times_{\mathcal{B}} \mathcal{X},\mathscr{E}) & \xrightarrow{p\circ\operatorname{pr}_{\mathcal{X}}} & {}_\natural\mathcal{B} \\ \downarrow{\scriptstyle(\operatorname{id},p)} & & \downarrow{\scriptstyle\operatorname{ev}_0} & & \\ \operatorname{Ar}(\mathcal{T}^{op})^\sharp \times_{\mathcal{T}^{op}} {}_\natural\mathcal{B} & \xrightarrow{\operatorname{pr}_{\mathcal{B}}} & {}_\natural\mathcal{B} & & \\ \downarrow{\scriptstyle\operatorname{ev}_0} & & & & \\ (\mathcal{T}^{op})^\sharp & & & & \end{array}$$

where j is the composite $\operatorname{Ar}(\mathcal{T}^{op}) \times_{\mathcal{T}^{op}} \mathcal{X} \xrightarrow{\operatorname{pr}_{\mathcal{X}}} \mathcal{X} \xrightarrow{p} \mathcal{B} \xrightarrow{\iota} \operatorname{Ar}^{cocart}(\mathcal{B})$, ι being the identity section. Let

$$i : \operatorname{Ar}(\mathcal{T}^{op})^\sharp \times_{\mathcal{T}^{op}} {}_\natural\mathcal{X} \longrightarrow (\operatorname{Ar}(\mathcal{T}^{op})^\sharp \times_{\mathcal{T}^{op}} {}_\natural\mathcal{B}) \times_{{}_\natural\mathcal{B}} (\operatorname{Ar}^{cocart}(\mathcal{B}) \times_{\mathcal{B}} \mathcal{X},\mathscr{E})$$

denote the induced map to the pullback. By [Sha21, Lem. 9.12], i is a homotopy equivalence with respect to the projection to $\mathcal{X}$. By [Sha21, Lem. 2.27] and Lemma 4.8, we obtain an equivalence of $\mathcal{T}$-∞-categories

$$\underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{B}, \widetilde{\mathrm{Fun}}_{\mathcal{B},\mathcal{T}}(\mathcal{X},\mathcal{Y})) \xrightarrow{\simeq} \underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{X},\mathcal{Y}).$$

□

4.10. **Remark.** In the statement of Theorem 4.9, if we replace the span

$$\natural\mathcal{B} \xleftarrow{\mathrm{ev}_0} (\mathrm{Ar}^{cocart}(\mathcal{B}) \times_{\mathcal{B}} \mathcal{X}, \mathscr{E}) \xrightarrow{p \circ \mathrm{pr}_{\mathcal{X}}} \natural\mathcal{B}$$

with

$$\natural\mathcal{B} \xleftarrow{\mathrm{ev}_0} (\mathrm{Ar}^{cocart}(\mathcal{B}) \times_{\mathcal{B}} \mathcal{X}, \mathscr{E}) \xrightarrow{\mathrm{pr}_{\mathcal{X}}} \natural\mathcal{X}$$

then the same argument as in the proof of Theorem 4.9 shows that for all $\mathcal{T}$-fibrations $\mathcal{D} \longrightarrow \mathcal{X}$, we have a canonical and natural equivalence[20]

$$\underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C}, (\mathrm{ev}_0)_*(\mathrm{pr}_{\mathcal{X}})^*\mathcal{D}) \xrightarrow{\simeq} \underline{\mathrm{Fun}}_{/\mathcal{X},\mathcal{T}}(\mathcal{C} \times_{\mathcal{B}} \mathcal{X}, \mathcal{D}).$$

Passing first to cocartesian sections and then to mapping spaces, this shows that at the level of underlying ∞-categories, $(\mathrm{ev}_0)_*(\mathrm{pr}_{\mathcal{X}})^* : (\mathbf{Cat}_{\mathcal{T}})^{/\mathcal{X}} \longrightarrow (\mathbf{Cat}_{\mathcal{T}})^{/\mathcal{B}}$ computes the right adjoint to p^*. This justifies the terminology of "$\mathcal{T}$-flat fibration" since these are indeed exponentiable in the parametrized sense. Moreover, we then see that

$$\widetilde{\mathrm{Fun}}_{\mathcal{B},\mathcal{T}}(\mathcal{X}, -) \simeq p_* p^*(-)$$

as endofunctors of $(\mathbf{Cat}_{\mathcal{T}})^{/\mathcal{B}}$.

4.11. **Remark.** Suppose $\mathcal{X}, \mathcal{Y} \longrightarrow \mathcal{B}$ are $\mathcal{T}$-cocartesian fibrations and let $\underline{\mathrm{Fun}}_{\mathcal{B}}(\mathcal{X},\mathcal{Y})$ denote the internal hom construction of [Sha21, §3],[21] so that $\underline{\mathrm{Fun}}_{\mathcal{B}}(\mathcal{X},\mathcal{Y}) \longrightarrow \mathcal{B}$ is a $\mathcal{T}$-cocartesian fibration. Consider the morphism of spans

$$\begin{array}{ccccc} & & (\mathrm{Ar}^{cocart}(\mathcal{B}) \times_{\mathcal{B}} \mathcal{X}, \mathscr{E}) & & \\ & \swarrow & \downarrow{\scriptstyle (i,\mathrm{id})} & \searrow & \\ \natural\mathcal{B} & \longleftarrow & \mathrm{Ar}(\mathcal{B})^\sharp \times_{\mathcal{B}} \natural\mathcal{X} & \longrightarrow & \natural\mathcal{B} \end{array}$$

in which i is the inclusion $\mathrm{Ar}^{cocart}(\mathcal{B}) \subset \mathrm{Ar}(\mathcal{B})$. Then this morphism induces a $\mathcal{T}$-functor over $\mathcal{B}$

$$\rho : \underline{\mathrm{Fun}}_{\mathcal{B}}(\mathcal{X},\mathcal{Y}) \longrightarrow \widetilde{\mathrm{Fun}}_{\mathcal{B},\mathcal{T}}(\mathcal{X},\mathcal{Y}).$$

that upon passage to cocartesian sections in the source, regarded as $\mathcal{T}$-sections in the target, induces the inclusion

$$\mathrm{Fun}_{\mathcal{B}}(\mathcal{X},\mathcal{Y}) \longrightarrow \mathrm{Fun}_{/\mathcal{B},\mathcal{T}}(\mathcal{X},\mathcal{Y}).$$

Beware that even if $\mathcal{X}$ is in addition $\mathcal{T}$-cartesian so that $\widetilde{\mathrm{Fun}}_{\mathcal{B},\mathcal{T}}(\mathcal{X},\mathcal{Y})$ is $\mathcal{T}$-cocartesian, ρ will not preserve cocartesian edges in general; indeed, one observes that the above functor (i, id) does not carry the marking $\mathscr{E}'$ of Recollection 4.3 to marked edges in the target. Nonetheless, we have the following proposition.

4.12. **Proposition.** *In the situation of Remark 4.11, if $\mathcal{X} \simeq \mathcal{B} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{K}$ for some $\mathcal{T}$-∞-category $\mathcal{K}$, then the comparison $\mathcal{T}$-functor ρ implements an equivalence*

$$\rho : \underline{\mathrm{Fun}}_{\mathcal{B}}(\mathcal{B} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{K}, \mathcal{Y}) \xrightarrow{\simeq} \widetilde{\mathrm{Fun}}_{\mathcal{B},\mathcal{T}}(\mathcal{B} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{K}, \mathcal{Y})$$

of $\mathcal{T}$-cocartesian fibrations over $\mathcal{B}$. Consequently, for every $\mathcal{T}$-cocartesian fibration $\mathcal{C} \longrightarrow \mathcal{B}$, the equivalence of Theorem 4.9 restricts to

$$\underline{\mathrm{Fun}}_{\mathcal{B}}(\mathcal{C}, \widetilde{\mathrm{Fun}}_{\mathcal{B},\mathcal{T}}(\mathcal{B} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{K}, \mathcal{Y})) \simeq \underline{\mathrm{Fun}}_{\mathcal{B}}(\mathcal{C} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{K}, \mathcal{Y}).$$

---

[20] Here, $(\mathrm{ev}_0)_*(\mathrm{pr}_{\mathcal{X}})^* : \mathbf{sSet}^+_{/\natural\mathcal{X}} \longrightarrow \mathbf{sSet}^+_{/\natural\mathcal{B}}$ and $(\mathrm{ev}_0)_*(\mathrm{pr}_{\mathcal{X}})^*\mathcal{D} := (\mathrm{ev}_0)_*(\mathrm{pr}_{\mathcal{X}})^*(\natural\mathcal{D})$ regarded as a $\mathcal{T}$-fibration over $\mathcal{B}$.

[21] We mildly abuse our notational conventions by writing $\underline{\mathrm{Fun}}_{\mathcal{B}}(-,-)$ instead of $\underline{\mathrm{Fun}}_{\mathcal{B}^{\mathrm{op}}}(-,-)$ as we would do if $\mathcal{B} = *_{\mathcal{T}} = \mathcal{T}^{\mathrm{op}}$.

Proof. The consequence will follow immediately from the universal property of $\underline{\mathrm{Fun}}_{\mathcal{B}}(-,-)$ once we establish the first claim. For this, first observe that since $\mathcal{X} \simeq \mathcal{B} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{K}$, $\mathcal{X}$ is both a $\mathcal{T}$-cocartesian and $\mathcal{T}$-cartesian fibration over $\mathcal{B}$ such that the fiberwise cartesian edges, fiberwise cocartesian edges, and fiberwise equivalences all coincide in $\mathcal{X}$. In particular, the functor (i, id) in Remark 4.11 carries the class $\mathscr{E}'$ of Recollection 4.3 into the marked edges of $\mathrm{Ar}(\mathcal{B})^{\sharp} \times_{\mathcal{B}} {}_{\natural}\mathcal{X}$, so ρ is a morphism of $\mathcal{T}$-cocartesian fibrations. It therefore suffices to check the claimed equivalence fiberwise.

Given $b \in \mathcal{B}$ over $t \in \mathcal{T}^{\mathrm{op}}$, we may replace $\mathcal{B}$ by $\mathcal{B}^{b/}$ and $\mathcal{T}$ by $(\mathcal{T}^{/t})^{\mathrm{op}}$, so it further suffices to check that ρ induces an equivalence upon passage to cocartesian sections. But this is the map

$$\mathrm{Fun}_{\mathcal{B}}(\mathcal{X}, \mathcal{Y}) \xrightarrow{\simeq} \mathrm{Fun}^{\mathcal{T}\text{-}cocart}_{/\mathcal{B},\mathcal{T}}(\mathcal{X}, \mathcal{Y}).$$

Indeed, for any $\mathcal{T}$-cartesian fibration $\mathcal{X}$ the cocartesian sections of $\widetilde{\mathrm{Fun}}_{\mathcal{B},\mathcal{T}}(\mathcal{X}, \mathcal{Y})$ is the full subcategory of $\mathrm{Fun}_{/\mathcal{B},\mathcal{T}}(\mathcal{X}, \mathcal{Y})$ spanned by those $\mathcal{T}$-functors $F : \mathcal{X} \longrightarrow \mathcal{Y}$ over $\mathcal{B}$ that carry fiberwise cartesian edges to fiberwise cocartesian edges, but in our case F equivalently preserves cocartesian edges. □

4.1. **Application: parametrized (co)limits in section $\mathcal{T}$-∞-categories.** We next use the $\mathcal{T}$-pairing construction to analyze $\mathcal{T}$-limits and $\mathcal{T}$-colimits in a $\mathcal{T}$-∞-category of sections. Actually, we work in somewhat greater generality: given a $\mathcal{T}$-cocartesian fibration $\mathcal{X} \longrightarrow \mathcal{B}$ and a $\mathcal{T}$-fibration $\mathcal{C} \longrightarrow \mathcal{B}$, we will study $\mathcal{T}$-(co)limits in $\underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C}, \mathcal{X})$ (Theorem 4.16). First, we introduce some terminology concerning relative adjunctions, extending [Sha21, Def. 8.3].

4.13. **Definition.** Let $\mathcal{X}, \mathcal{Y} \longrightarrow \mathcal{B}$ be $\mathcal{T}$-fibrations and let

$$F \colon \mathcal{X} \rightleftarrows \mathcal{Y} : G$$

be a relative adjunction with respect to the structure maps to $\mathcal{B}$ (in the sense of [Lur17, Def. 7.3.2.2]). We then say that $F \dashv G$ is a $\mathcal{B}$-*relative* $\mathcal{T}$-*adjunction* if F and G are $\mathcal{T}$-functors.

4.14. **Remark** (Stability under base-change)**.** Suppose

$$F \colon \mathcal{X} \rightleftarrows \mathcal{Y} : G$$

is a $\mathcal{B}$-relative $\mathcal{T}$-adjunction and $\phi : \mathcal{C} \longrightarrow \mathcal{B}$ is a $\mathcal{T}$-functor. By [Lur17, Prop. 7.3.2.5], the pullback

$$F_{\mathcal{C}} \colon \mathcal{X} \times_{\mathcal{B}} \mathcal{C} \rightleftarrows \mathcal{Y} \times_{\mathcal{B}} \mathcal{C} : G_{\mathcal{C}}$$

is then a $\mathcal{C}$-relative $\mathcal{T}$-adjunction.

The following lemma illustrates the basic asymmetry between $\mathcal{B}$-relative left and right $\mathcal{T}$-adjoints that should already be familiar from the theory of relative adjunctions (compare [Lur17, Prop. 7.3.2.6] versus [Lur17, Prop. 7.3.2.11].)

4.15. **Lemma.** *Suppose $\mathcal{X}, \mathcal{Y} \longrightarrow \mathcal{B}$ are $\mathcal{T}$-cocartesian fibrations.*

(1) Let $F : \mathcal{X} \longrightarrow \mathcal{Y}$ be a morphism of $\mathcal{T}$-cocartesian fibrations over $\mathcal{B}$. Then F admits a $\mathcal{B}$-relative right $\mathcal{T}$-adjoint $R : \mathcal{Y} \longrightarrow \mathcal{X}$ if and only if for all $b \in \mathcal{B}_t$, the parametrized fiber $F_{\underline{b}} : \mathcal{X}_{\underline{b}} \longrightarrow \mathcal{Y}_{\underline{b}}$ admits a right $\mathcal{T}^{/t}$-adjoint $R_{\underline{b}}$.

(2) Let $F : \mathcal{X} \longrightarrow \mathcal{Y}$ be a $\mathcal{T}$-functor over $\mathcal{B}$. Then F admits a $\mathcal{B}$-relative left $\mathcal{T}$-adjoint $L : \mathcal{Y} \longrightarrow \mathcal{X}$ if and only if for all $b \in \mathcal{B}_t$, the parametrized fiber $F_{\underline{b}} : \mathcal{X}_{\underline{b}} \longrightarrow \mathcal{Y}_{\underline{b}}$ admits a left $\mathcal{T}^{/t}$-adjoint $L_{\underline{b}}$, and for all fiberwise morphisms $f : b \longrightarrow b'$ in $\mathcal{B}_t$, the natural transformation

$$\begin{array}{ccc} \mathcal{Y}_b & \xrightarrow{L_b} & \mathcal{X}_b \\ {\scriptstyle f_!}\downarrow & \nearrow & \downarrow{\scriptstyle f_!} \\ \mathcal{Y}_{b'} & \xrightarrow[L_{b'}]{} & \mathcal{X}_{b'} \end{array} \quad \textit{adjoint to} \quad \begin{array}{ccc} \mathcal{Y}_b & \xleftarrow{F_b} & \mathcal{X}_b \\ {\scriptstyle f_!}\downarrow & \searrow & \downarrow{\scriptstyle f_!} \\ \mathcal{Y}_{b'} & \xleftarrow[F_{b'}]{} & \mathcal{X}_{b'} \end{array}$$

is an equivalence. Moreover, in this case L is a morphism of $\mathcal{T}$-cocartesian fibrations over $\mathcal{B}$.

Proof. (1): By the opposite of [Lur17, Prop. 7.3.2.6], F admits a $\mathcal{B}$-relative right adjoint R if and only if for all $b \in \mathcal{B}$, F_b admits a right adjoint R_b. But we are then reduced to showing that R is in addition a $\mathcal{T}$-functor if and only if $R_{\underline{b}}$ is in addition a $\mathcal{T}^{/t}$-functor for all $b \in \mathcal{B}$, which is clear.
(2): Since every morphism in $\mathcal{B}$ factors as the composite of a cocartesian edge and a fiberwise morphism, the claim follows directly from [Lur17, Prop. 7.3.2.11]. □

We may now state the main result of this subsection. Note that the cases of parametrized limits and colimits involve different hypotheses (as should be familiar from the theory of limits and colimits in ∞-categories of algebras).

4.16. **Theorem.** *Let $p : \mathcal{X} \longrightarrow \mathcal{B}$ be a $\mathcal{T}$-cocartesian fibration, let $\mathcal{K}$ be a $\mathcal{T}$-∞-category, and let $r : \mathcal{C} \longrightarrow \mathcal{B}$ be any $\mathcal{T}$-fibration.*

(1) There exists a $\mathcal{B}$-relative constant $\mathcal{K}$-indexed diagram $\mathcal{T}$-functor

$$\delta_p : \mathcal{X} \longrightarrow \widetilde{\mathrm{Fun}}_{\mathcal{B},\mathcal{T}}(\mathcal{B} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{K}, \mathcal{X}),$$

which is a morphism of $\mathcal{T}$-cocartesian fibrations over $\mathcal{B}$, such that the constant $\mathcal{K}$-indexed diagram $\mathcal{T}$-functor

$$\delta_{r,p} : \underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C}, \mathcal{X}) \longrightarrow \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K}, \underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C}, \mathcal{X}))$$

is given by $\underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C}, \delta_p)$.

(2) Suppose that for every $b \in \mathcal{B}_t$, $\mathcal{X}_{\underline{b}}$ admits all $\mathcal{K}_{\underline{t}}$-indexed $\mathcal{T}^{/t}$-limits. Then δ_p admits a $\mathcal{B}$-relative $\mathcal{T}$-right adjoint

$$\lim{}^{\mathcal{B},\mathcal{T}} : \widetilde{\mathrm{Fun}}_{\mathcal{B},\mathcal{T}}(\mathcal{B} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{K}, \mathcal{X}) \longrightarrow \mathcal{X}$$

which for all $b \in \mathcal{B}_t$ restricts to the $\mathcal{T}^{/t}$-limit $\mathcal{T}^{/t}$-functor

$$\lim{}^{\mathcal{T}^{/t}} : \underline{\mathrm{Fun}}_{\mathcal{T}^{/t}}(\mathcal{K}_{\underline{t}}, \mathcal{X}_{\underline{b}}) \longrightarrow \mathcal{X}_{\underline{b}}.$$

Consequently, $\delta_{r,p}$ admits a $\mathcal{T}$-right adjoint $\lim^{\mathcal{T}}$ given by $\underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C}, \lim^{\mathcal{B},\mathcal{T}})$.

(3) A $\mathcal{T}^{/t}$-functor

$$\overline{f} : \mathcal{K}^{\triangleleft}_{\underline{t}} \longrightarrow \underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C}, \mathcal{X})_{\underline{t}}$$

is a $\mathcal{T}^{/t}$-limit diagram, resp. f admits a $\mathcal{T}^{/t}$-limit, if for all $\alpha : s \longrightarrow t$ in $\mathcal{T}$ and $c \in \mathcal{C}_s$ over $b \in \mathcal{B}_s$, the composite $\mathcal{T}^{/s}$-functor

$$\overline{f_c} : \mathcal{K}^{\triangleleft}_{\underline{s}} \xrightarrow{f_\alpha} \underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C}, \mathcal{X})_{\underline{s}} \xrightarrow{\mathrm{ev}_c} \underline{\mathrm{Fun}}_{/\mathcal{B}_{\underline{s}},\mathcal{T}^{/s}}(\underline{c}, \mathcal{X}_{\underline{s}}) \simeq \mathcal{X}_{\underline{b}}$$

is a $\mathcal{T}^{/s}$-limit diagram, resp. f_c admits a $\mathcal{T}^{/s}$-limit.

(4) Suppose that for every $b \in \mathcal{B}_t$, $\mathcal{X}_{\underline{b}}$ admits all $\mathcal{K}_{\underline{t}}$-indexed $\mathcal{T}^{/t}$-colimits, and for every morphism $f : b \longrightarrow b'$ in $\mathcal{B}_t$, the pushforward $\mathcal{T}^{/t}$-functor $f_! : \mathcal{X}_{\underline{b}} \longrightarrow \mathcal{X}_{\underline{b'}}$ preserves $\mathcal{K}_{\underline{t}}$-indexed $\mathcal{T}^{/t}$-colimits. Then δ_p admits a $\mathcal{B}$-relative $\mathcal{T}$-left adjoint

$$\mathrm{colim}^{\mathcal{B},\mathcal{T}} : \widetilde{\mathrm{Fun}}_{\mathcal{B},\mathcal{T}}(\mathcal{B} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{K}, \mathcal{X}) \longrightarrow \mathcal{X}$$

which for all $b \in \mathcal{B}_t$ restricts to the $\mathcal{T}^{/t}$-colimit $\mathcal{T}^{/t}$-functor

$$\mathrm{colim}^{\mathcal{T}^{/t}} : \underline{\mathrm{Fun}}_{\mathcal{T}^{/t}}(\mathcal{K}_{\underline{t}}, \mathcal{X}_{\underline{b}}) \longrightarrow \mathcal{X}_{\underline{b}}.$$

Consequently, $\delta_{r,p}$ admits a $\mathcal{T}$-left adjoint $\mathrm{colim}^{\mathcal{T}}$ given by $\underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C}, \mathrm{colim}^{\mathcal{B},\mathcal{T}})$.

(5) A $\mathcal{T}^{/t}$-functor

$$\overline{f} : \mathcal{K}^{\triangleright}_{\underline{t}} \longrightarrow \underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C}, \mathcal{X})_{\underline{t}}$$

is a $\mathcal{T}^{/t}$-colimit diagram, resp. f admits a $\mathcal{T}^{/t}$-colimit, if for all $\alpha : s \longrightarrow t$ in $\mathcal{T}$ and $c \in \mathcal{C}_s$ over $b \in \mathcal{B}_s$, the composite $\mathcal{T}^{/s}$-functor

$$\overline{f_c} : \mathcal{K}^{\triangleright}_{\underline{s}} \xrightarrow{f_\alpha} \underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C}, \mathcal{X})_{\underline{s}} \xrightarrow{\mathrm{ev}_c} \underline{\mathrm{Fun}}_{/\mathcal{B}_{\underline{s}},\mathcal{T}^{/s}}(\underline{c}, \mathcal{X}_{\underline{s}}) \simeq \mathcal{X}_{\underline{b}}$$

is a $\mathcal{T}^{/s}$-colimit diagram (resp. f_c admits a $\mathcal{T}^{/s}$-colimit), and for all $c \longrightarrow c' \in \mathcal{C}_s$ over $g : b \longrightarrow b' \in \mathcal{B}_s$, $g_! \circ \overline{f_c}$ is a $\mathcal{T}^{/s}$-colimit diagram (resp. $g_!$ preserves the $\mathcal{T}^{/s}$-colimit of f_c).

Proof. (1): Using Proposition 4.12, we may define δ_p as adjoint to the projection $\mathcal{X} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{K} \longrightarrow \mathcal{X}$, since this is a morphism of $\mathcal{T}$-cocartesian fibrations over $\mathcal{B}$, and by construction this has the indicated property.
(2): Under our assumption, the existence of $\lim^{\mathcal{B},\mathcal{T}}$ follows immediately from Lemma 4.15(1). For the consequence, note that we have an equivalence of $\mathcal{T}$-∞-categories

$$\begin{aligned}\underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K}, \underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C}, \mathcal{X})) &\simeq \underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{K}, \mathcal{X}) \\ &\simeq \underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C}, \widetilde{\mathrm{Fun}}_{\mathcal{B},\mathcal{T}}(\mathcal{B} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{K}, \mathcal{X}))\end{aligned}$$

where the first equivalence holds by the universal property of $\underline{\mathrm{Fun}}_{\mathcal{T}}(-,-)$ and the definition of $\underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C},\mathcal{X})$ as a pullback, and the second equivalence holds by Theorem 4.9. It thus suffices to show that $\underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C},-)$ covariantly transforms $\mathcal{B}$-relative $\mathcal{T}$-adjunctions into $\mathcal{T}$-adjunctions. For this, by Remark 4.14 we may suppose that $\mathcal{C}=\mathcal{B}$ without loss of generality, in which case the assertion is [Sha21, Cor. 8.5].
(3): This follows similarly to (2), but where we now consider how $\underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C},-)$ transforms $\lim^{\mathcal{B},\mathcal{T}}$ as a partially defined $\mathcal{B}$-relative right $\mathcal{T}$-adjoint (under the given hypotheses on $\overline{f_c}$) to $\lim^{\mathcal{T}}$ as a partially defined right $\mathcal{T}$-adjoint.
(4) and (5): These are proven as for (2) and (3) but using Lemma 4.15(2) instead. □

4.17. **Corollary.** *Let $\mathcal{X}\longrightarrow\mathcal{B}$ be a $\mathcal{T}$-cocartesian fibration and let $\mathcal{C}\longrightarrow\mathcal{B}$ be a $\mathcal{T}$-fibration. Let $\mathcal{K}=\{\mathcal{K}_t : t\in\mathcal{T}\}$ be a collection of classes $\mathcal{K}_t$ of small $\mathcal{T}^{/t}$-∞-categories closed with respect to base-change in $\mathcal{T}$.*

1. *Suppose that for all $b\in\mathcal{B}_t$, $\mathcal{X}_{\underline{b}}$ admits all $\mathcal{K}_t$-indexed $\mathcal{T}^{/t}$-limits. Then $\underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C},\mathcal{X})$ strongly admits all $\mathcal{K}$-indexed $\mathcal{T}$-limits.*
2. *Suppose that for all $b\in\mathcal{B}_t$, $\mathcal{X}_{\underline{b}}$ admits all $\mathcal{K}_t$-indexed $\mathcal{T}^{/t}$-colimits, and for all $g: b\longrightarrow b'\in\mathcal{B}_t$, the pushforward $\mathcal{T}^{/t}$-functor $g_! : \mathcal{X}_{\underline{b}}\longrightarrow\mathcal{X}_{\underline{b'}}$ preserves all $\mathcal{K}_t$-indexed $\mathcal{T}^{/t}$-colimits. Then $\underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C},\mathcal{X})$ strongly admits all $\mathcal{K}$-indexed $\mathcal{T}$-colimits.*

Proof. We show how to deduce (1) from Theorem 4.16, the proof of (2) being similar. For this, the only additional point to note is that for any $\mathcal{K}\in\mathcal{K}_t$, by base-change of the given data to lie over $\mathcal{T}^{/t}$ we may apply Theorem 4.16 under our hypotheses to show that $\underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C},\mathcal{X})_{\underline{t}}$ admits all $\mathcal{K}$-indexed $\mathcal{T}^{/t}$-limits. □

5. Relative parametrized colimits

In this section and the next we work towards the proof of Theorem A.

5.1. **Definition.** Suppose we have a commutative diagram of $\mathcal{T}$-∞-categories

$$\begin{array}{ccc} \mathcal{K} & \xrightarrow{p} & \mathcal{C} \\ {\scriptstyle i}\downarrow & \overset{\overline{p}}{\nearrow} & \downarrow{\scriptstyle \pi} \\ \mathcal{K}^{\trianglerighteq} & \xrightarrow{\overline{q}} & \mathcal{B} \end{array}$$

in which π is a $\mathcal{T}$-fibration. Let $q=\pi p=\overline{q}i$. We say that $\overline{p}$ is a *weak π-$\mathcal{T}$-colimit diagram* if the $\mathcal{T}$-functor

$$*_{\mathcal{T}}\longrightarrow *_{\mathcal{T}}\times_{\sigma_{\overline{q}},\mathcal{B}^{(q,\mathcal{T})/}}\mathcal{C}^{(p,\mathcal{T})/}$$

induced by $\sigma_{\overline{p}}$ is a $\mathcal{T}$-initial object.

We say that $\overline{p}$ is a *π-$\mathcal{T}$-colimit diagram* if the $\mathcal{T}$-functor

$$*_{\mathcal{T}}\longrightarrow \mathcal{B}^{(\overline{q},\mathcal{T})/}\times_{\mathcal{B}^{(q,\mathcal{T})/}}\mathcal{C}^{(p,\mathcal{T})/}$$

induced by $\sigma_{\overline{p}}$ is a $\mathcal{T}$-initial object. (Here, the projection to the first factor is induced by $\sigma_{\overline{q}'}$ for $\overline{q}'$ given by the composite $\mathcal{K}\star_{\mathcal{T}^{\mathrm{op}}}(\Delta^1\times\mathcal{T}^{\mathrm{op}})\xrightarrow{\mathrm{id}\star\mathrm{const}}\mathcal{K}^{\trianglerighteq}\xrightarrow{\overline{q}}\mathcal{B}$.)

5.2. **Example.** For $\mathcal{T}=\Delta^0$ and $\mathcal{K}=\Delta^0$, weak π-colimit diagrams are locally π-cocartesian edges, whereas π-colimit diagrams are π-cocartesian edges.

5.3. **Remark.** For Definition 5.1, $\overline{p}$ is a π-$\mathcal{T}$-colimit diagram if and only if the $\mathcal{T}$-functor

$$\mathcal{C}^{(\overline{p},\mathcal{T})/}\longrightarrow\mathcal{B}^{(\overline{q},\mathcal{T})/}\times_{\mathcal{B}^{(q,\mathcal{T})/}}\mathcal{C}^{(p,\mathcal{T})/}$$

is an equivalence of $\mathcal{T}$-∞-categories, or equivalently the commutative square

$$\begin{array}{ccc} \mathcal{C}^{(\overline{p},\mathcal{T})/} & \longrightarrow & \mathcal{C}^{(p,\mathcal{T})/} \\ \downarrow & & \downarrow \\ \mathcal{B}^{(\overline{q},\mathcal{T})/} & \longrightarrow & \mathcal{B}^{(q,\mathcal{T})/} \end{array}$$

is a homotopy pullback square (using Lemma 5.4(1)). This is ultimately because for any $\mathcal{T}$-category $\mathcal{E}$, a $\mathcal{T}$-functor $\sigma: *_{\mathcal{T}}\longrightarrow\mathcal{E}$ is a $\mathcal{T}$-initial object if and only if $\mathcal{E}^{(\sigma,\mathcal{T})/}\longrightarrow\mathcal{E}$ is an equivalence.

We now collect a few lemmas that will feature in the proof of our main result (Proposition 5.8) on the existence of π-$\mathcal{T}$-colimits. We first state a parametrized analogue of [Lur09, Prop. 4.2.1.6].

5.4. **Lemma.** *Suppose we have a commutative diagram of $\mathcal{T}$-∞-categories*

$$\begin{array}{ccc} \mathcal{K} & \xrightarrow{p} & \mathcal{C} \\ {\scriptstyle i}\big\downarrow & \overset{\overline{p}}{\nearrow} & \big\downarrow{\scriptstyle \pi} \\ \mathcal{L} & \xrightarrow{\overline{q}} & \mathcal{B}. \end{array}$$

in which i is a monomorphism. Let $q = \pi \circ p = \overline{q} \circ i$ and let

$$\psi : \mathcal{C}^{(\overline{p},\mathcal{T})/} \longrightarrow \mathcal{C}^{(p,\mathcal{T})/} \times_{\mathcal{B}^{(q,\mathcal{T})/}} \mathcal{B}^{(\overline{q},\mathcal{T})/}$$

denote the induced $\mathcal{T}$-functor.

(1) If π is a categorical fibration, then

$$\phi : \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{L}, \mathcal{C}) \longrightarrow \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K}, \mathcal{C}) \times_{\underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K},\mathcal{B})} \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{L}, \mathcal{B})$$

is a categorical fibration, and ψ is a left fibration.

(2) Suppose that π is a $\mathcal{T}$-cocartesian fibration and let M_C denote the π-cocartesian edges in $\mathcal{C}$. Suppose that we have fiberwise markings $\{(M_K)_t\}$ on $\mathcal{K}$ and $\{(M_L)_t\}$ on $\mathcal{L}$ that are stable under base-change (i.e., for all $f : s \longrightarrow t \in \mathcal{T}$, $f^*(M_K)_t \subset (M_K)_s$). Let M_K be the minimal subset of the edges on $\mathcal{K}$ closed under composition that contains the cocartesian edges and $\{(M_K)_t\}$, and similarly define M_L. Let $\underline{\mathrm{Fun}}_{\mathcal{T}}((\mathcal{L}, M_L), (\mathcal{C}, M_C))$, etc. be the full $\mathcal{T}$-subcategories spanned by those $\mathcal{T}^{/t}$-functors that preserve the additional markings, and let

$$\phi' : \underline{\mathrm{Fun}}_{\mathcal{T}}((\mathcal{L}, M_L), (\mathcal{C}, M_C)) \longrightarrow \underline{\mathrm{Fun}}_{\mathcal{T}}((\mathcal{K}, M_K), (\mathcal{C}, M_C)) \times_{\underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K},\mathcal{B})} \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{L}, \mathcal{B})$$

be the restriction of ϕ. Then if $i : (\mathcal{K}, M_K) \longrightarrow (\mathcal{L}, M_L)$ is a cocartesian equivalence in $\mathbf{sSet}^+_{/\mathcal{T}^{\mathrm{op}}}$, ϕ' is a trivial fibration. Moreover, if $\overline{p}$ then sends M_L into M_C, ψ is a trivial fibration.

Proof. (1): It suffices to show that ϕ is a fibration in $\mathbf{sSet}^+_{/\mathcal{T}^{\mathrm{op}}}$ where we mark the cocartesian edges. This follows as in the proof of [Sha21, Lem. 3.5(1)]. Considering this categorical fibration for both i and $i^{\trianglerighteq}$ then shows ψ is a categorical fibration by a base-change argument. Since a functor between left fibrations over a common base that is a categorical fibration is necessarily a left fibration, to then show that ψ is a left fibration it suffices to show that $\mathcal{C}^{(f,\mathcal{T})/} \longrightarrow \mathcal{C}$ is a left fibration for any $\mathcal{T}$-functor $f : \mathcal{J} \longrightarrow \mathcal{C}$. But this is a consequence of the $\mathcal{T}$-functor

$$\underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{J}^{\trianglerighteq}, \mathcal{C}) \longrightarrow \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{J}, \mathcal{C}) \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{C}$$

being a $\mathcal{T}$-bifibration (cf. [Sha21, Ex. 7.10] and [Lur09, Rem. 2.4.7.4] for the stronger conclusion that $\mathcal{C}^{(f,\mathcal{T})/} \longrightarrow \mathcal{C}$ is a left fibration and not just a $\mathcal{T}$-cocartesian fibration).

(2): Since ϕ' is a categorical fibration by (1), it suffices to show that ϕ'_t is an equivalence for all $t \in \mathcal{T}$. After replacing $\mathcal{T}^{/t}$ with $\mathcal{T}$, we thus reduce to checking that

$$\widehat{\phi'} : \mathrm{Fun}_{\mathcal{T}}((\mathcal{L}, M_L), (\mathcal{C}, M_C)) \longrightarrow \mathrm{Fun}_{\mathcal{T}}((\mathcal{K}, M_K), (\mathcal{C}, M_C)) \times_{\mathrm{Fun}_{\mathcal{T}}(\mathcal{K},\mathcal{B})} \mathrm{Fun}_{\mathcal{T}}(\mathcal{L}, \mathcal{B})$$

is a trivial fibration. Let $A \longrightarrow B$ be any cofibration of simplicial sets. The relevant lifting problem then transposes to

$$\begin{array}{ccc} A^\flat \times (\mathcal{L}, M_K) \bigcup_{A^\flat \times (\mathcal{K}, M_K)} B^\flat \times (\mathcal{K}, M_K) & \longrightarrow & (\mathcal{C}, M_C) \\ \big\downarrow & \nearrow & \big\downarrow \\ B^\flat \times (\mathcal{L}, M_L) & \longrightarrow & \mathcal{B}^\sharp. \end{array}$$

Now because trivial cofibrations in the cocartesian model structure on $\mathbf{sSet}^+_{/\mathcal{T}^{\mathrm{op}}}$ are stable under taking pushout-products with arbitrary cofibrations in $\mathbf{sSet}^+$ [Lur09, Cor. 3.1.4.3], there exists a dotted lift. The assertion about ψ then follows as in (1) by a base-change argument. □

We have an elementary observation about lifting $\mathcal{T}$-initial objects along a $\mathcal{T}$-cocartesian fibration.

5.5. **Lemma.** *Let $\pi : \mathcal{C} \longrightarrow \mathcal{B}$ be a $\mathcal{T}$-cocartesian fibration and suppose that $\sigma : \mathcal{T}^{\mathrm{op}} \longrightarrow \mathcal{B}$ is a $\mathcal{T}$-initial object. Let $\widetilde{\sigma} : \mathcal{T}^{\mathrm{op}} \longrightarrow \mathcal{C}$ be a $\mathcal{T}$-functor lift of σ. Suppose that:*

(1) $\widetilde{\sigma}$ *is a* $\mathcal{T}$*-initial object in* $\mathcal{T}^{\mathrm{op}} \times_{\sigma,\mathcal{B}} \mathcal{C}$.
(2) For all $t \in \mathcal{T}$ *and morphisms* $f : \sigma(t) \longrightarrow y \in \mathcal{B}_t$*, the pushforward* $\mathcal{T}^{/t}$*-functor* $f_! : \mathcal{C}_{\underline{\sigma(t)}} \longrightarrow \mathcal{C}_{\underline{y}}$ *preserves* $\mathcal{T}^{/t}$*-initial objects.*

Then $\widetilde{\sigma}$ *is a* $\mathcal{T}$*-initial object.*

Proof. We may check for all $t \in \mathcal{T}$ that $\widetilde{\sigma}(t)$ is an initial object in $\mathcal{C}_t$, using the known assertion when $\mathcal{T} = \Delta^0$. □

We can then bootstrap from Lemma 5.5 to understand relative $\mathcal{T}$-colimits originating from $\mathcal{T}$-colimits in the parametrized fibers.

5.6. **Lemma.** *Suppose we have a commutative diagram of* $\mathcal{T}$*-*∞*-categories*

$$\begin{array}{ccccc} \mathcal{K} & \xrightarrow{p_0} & \mathcal{T}^{\mathrm{op}} \times_{\mathcal{B}} \mathcal{C} & \longrightarrow & \mathcal{C} \\ \downarrow & \overset{\overline{p_0}}{\nearrow} & \downarrow & \overset{\overline{p}}{\nearrow} & \downarrow{\scriptstyle \pi} \\ \mathcal{K}^{\trianglerighteq} & \longrightarrow & \mathcal{T}^{\mathrm{op}} & \xrightarrow{\sigma} & \mathcal{B} \end{array} \qquad (p = \mathcal{K} \to \mathcal{C},\ \overline{q} = \mathcal{K}^{\trianglerighteq} \to \mathcal{B})$$

in which π *is a* $\mathcal{T}$*-cocartesian fibration and* $\overline{p_0}$ *is a* $\mathcal{T}$*-colimit diagram. Then* $\overline{p}$ *is a weak* π*-*$\mathcal{T}$*-colimit diagram.*

Suppose moreover that for every $t \in \mathcal{T}$ *and morphism* $f : \sigma(t) \longrightarrow y \in \mathcal{B}_t$*, the pushforward* $\mathcal{T}^{/t}$*-functor* $f_! : \mathcal{C}_{\underline{\sigma(t)}} \longrightarrow \mathcal{C}_{\underline{y}}$ *preserves the* $\mathcal{K}_{\underline{t}}$*-indexed* $\mathcal{T}^{/t}$*-colimit diagram given by* $(\overline{p_0})_{\underline{t}}$*. Then* $\overline{p}$ *is a* π*-*$\mathcal{T}^{/t}$*-colimit diagram.*

Proof. By Lemma 5.7, we have an equivalence $\mathcal{C}^{(p_0,\mathcal{T})/} \simeq \mathcal{T}^{\mathrm{op}} \times_{\mathcal{B}^{(q,\mathcal{T})/}} \mathcal{C}^{(p,\mathcal{T})/}$. Thus by definition, if $\overline{p_0}$ is a $\mathcal{T}$-colimit diagram, then $\overline{p}$ is a weak π-$\mathcal{C}$-colimit diagram.

For the second claim, we note that the fiberwise cofinal $\mathcal{T}$-functor $\mathcal{T}^{\mathrm{op}} \subset \mathcal{K}^{\trianglerighteq}$ given by inclusion of the $\mathcal{T}$-cone point induces an equivalence $\mathcal{B}^{(\overline{q},\mathcal{T})/} \xrightarrow{\simeq} \mathcal{B}^{(\sigma,\mathcal{T})/}$ by [Sha21, Thm. 6.7]. It thus suffices to check that the $\mathcal{T}$-functor

$$\begin{array}{ccc} \mathcal{T}^{\mathrm{op}} & \xrightarrow{\widetilde{\sigma}} & \mathcal{B}^{(\sigma,\mathcal{T})/} \times_{\mathcal{B}^{(\pi p,\mathcal{T})/}} \mathcal{C}^{(p,\mathcal{T})/} \\ & \underset{\sigma}{\searrow} & \downarrow{\scriptstyle \pi'} \\ & & \mathcal{B}^{(\sigma,\mathcal{T})/} \end{array}$$

induced by $\overline{p}$ is a $\mathcal{T}$-initial object (where we abuse notation and write σ also for the $\mathcal{T}$-initial object id_σ in $\mathcal{B}^{(\sigma,\mathcal{T})/}$). By Lemma 5.4(1), π' is a left fibration. Under the equivalence $\mathcal{B}^{(\sigma,\mathcal{T})/} \simeq \mathcal{T}^{\mathrm{op}} \times_{\sigma,\mathcal{B}} \mathrm{Ar}(\mathcal{B})$ of Observation 2.4, the objects of the base $\mathcal{B}^{(\sigma,\mathcal{T})/}$ are equivalently given by pairs $(t \in \mathcal{T}, f : \sigma(t) \longrightarrow y)$. A cocartesian section of the parameterized fiber $\pi'_{\underline{f}}$ is determined up to equivalence by a commutative diagram of $\mathcal{T}^{/t}$-∞-categories

$$\begin{array}{ccc} \mathcal{K}_{\underline{t}} & \xrightarrow{p_0'} & \mathcal{C}_{\underline{y}} \\ \downarrow & \overset{\overline{p_0}'}{\nearrow} & \downarrow \\ (\mathcal{K}_{\underline{t}})^{\trianglerighteq} & \longrightarrow & (\mathcal{T}^{/t})^{\mathrm{op}} \end{array}$$

and is a $\mathcal{T}^{/t}$-initial object if and only if $\overline{p_0}'$ is a $\mathcal{T}^{/t}$-colimit diagram. It is now clear that under our hypotheses, Lemma 5.5 applies to show that $\widetilde{\sigma}$ is a $\mathcal{T}$-initial object. □

5.7. **Lemma.** *Suppose we have a homotopy pullback square of* $\mathcal{T}$*-*∞*-categories*

$$\begin{array}{ccc} \mathcal{W} & \xrightarrow{f} & \mathcal{X} \\ \downarrow{\scriptstyle g} & & \downarrow{\scriptstyle h} \\ \mathcal{Y} & \xrightarrow{k} & \mathcal{Z} \end{array}$$

and a $\mathcal{T}$-functor $p : \mathcal{K} \longrightarrow \mathcal{W}$. Then the commutative square of $\mathcal{T}$-∞-categories

$$\begin{array}{ccc} \mathcal{W}^{(p,\mathcal{T})/} & \longrightarrow & \mathcal{X}^{(fp,\mathcal{T})/} \\ \downarrow & & \downarrow \\ \mathcal{Y}^{(gp,\mathcal{T})/} & \longrightarrow & \mathcal{Z}^{(hfp,\mathcal{T})/}. \end{array}$$

is a homotopy pullback square.

Proof. The proof is a straightforward diagram chase, starting from the known assertion that

$$\underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K}, -) : \mathbf{Cat}_{\mathcal{T}} \longrightarrow \mathbf{Cat}_{\mathcal{T}}$$

preserves limits. □

Finally, we arrive at our main existence result for relative $\mathcal{T}$-colimits.

5.8. **Proposition.** *Suppose we have a commutative diagram of $\mathcal{T}$-∞-categories*

$$\begin{array}{ccc} \mathcal{K} & \xrightarrow{p} & \mathcal{C} \\ {\scriptstyle i}\downarrow & \overset{\overline{p}}{\nearrow} & \downarrow{\scriptstyle \pi} \\ \mathcal{K}^{\underline{\rhd}} & \xrightarrow{\overline{q}} & \mathcal{B} \end{array}$$

in which $\pi : \mathcal{C} \longrightarrow \mathcal{B}$ is a $\mathcal{T}$-cocartesian fibration. Let $\sigma = \overline{q}|_{\mathcal{T}^{\mathrm{op}}}$. If for all $t \in \mathcal{T}$, the parametrized fiber $\mathcal{C}_{\underline{\sigma(t)}}$ admits $\mathcal{K}_{\underline{t}}$-indexed $\mathcal{T}^{/t}$-colimits, then there exists a filler $\overline{p} : \mathcal{K}^{\underline{\rhd}} \longrightarrow \mathcal{C}$ which is a weak π-$\mathcal{T}$-colimit diagram.

Moreover, suppose that for all morphisms $f : \sigma(t) \longrightarrow y \in \mathcal{B}_t$, the induced pushforward $\mathcal{T}^{/t}$-functor $f_! : \mathcal{C}_{\underline{\sigma(t)}} \longrightarrow \mathcal{C}_{\underline{y}}$ preserves $\mathcal{K}_{\underline{t}}$-indexed $\mathcal{T}^{/t}$-colimits. Then $\overline{p}$ is a π-$\mathcal{T}$-colimit diagram.

Proof. We prove this by reducing to Lemma 5.6. Let M_C denote the π-cocartesian edges in $\mathcal{C}$. First consider the diagram

$$\begin{array}{ccccc} \mathcal{K} \times \{0\} & & \xrightarrow{p} & & \mathcal{C} \\ {\scriptstyle i_0}\downarrow & & \overset{h}{\nearrow} & & \downarrow{\scriptstyle \pi} \\ \mathcal{K} \times \Delta^1 & \xrightarrow{f} & \mathcal{K}^{\underline{\rhd}} & \xrightarrow{\overline{q}} & \mathcal{B} \end{array}$$

where the map f is adjoint to $(\mathcal{K} = \mathcal{K}, \mathcal{K} \longrightarrow \mathcal{T})$. Because $i_0 : {}_\natural\mathcal{K} \times \{0\} \longrightarrow {}_\natural\mathcal{K} \times (\Delta^1)^\sharp$ is left marked anodyne, the dotted map $h : {}_\natural\mathcal{K} \times (\Delta^1)^\sharp \longrightarrow (\mathcal{C}, M_C)$ exists. Consider the two commutative squares

$$\begin{array}{ccc} \mathcal{K} \times \Delta^1 & \xrightarrow{h} & \mathcal{C} \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle \pi} \\ \mathcal{K}^{\underline{\rhd}} & \xrightarrow{\overline{q}} & \mathcal{B} \end{array} \quad , \quad \begin{array}{ccccc} \mathcal{K} & & \xrightarrow{p' := h|_{\mathcal{K} \times \{1\}}} & & \mathcal{C} \\ {\scriptstyle i}\downarrow & & & & \downarrow{\scriptstyle \pi} \\ \mathcal{K}^{\underline{\rhd}} & \longrightarrow & \mathcal{T}^{\mathrm{op}} & \xrightarrow{\sigma} & \mathcal{B} \end{array}$$

where the bottom composite $\mathcal{K}^{\underline{\rhd}} \longrightarrow \mathcal{B}$ is $\overline{q}'$.

We obtain a zig-zag

$$\begin{array}{ccccc} \mathcal{B}^{(\overline{q},\mathcal{T})/} \times_{\mathcal{B}^{(\pi p,\mathcal{T})/}} \mathcal{C}^{(p,\mathcal{T})/} & \xleftarrow{\psi} & \mathcal{B}^{(\overline{q},\mathcal{T})/} \times_{\mathcal{B}^{(\pi h,\mathcal{T})/}} \mathcal{C}^{(h,\mathcal{T})/} & \xrightarrow{\phi} & \mathcal{B}^{(\overline{q}',\mathcal{T})/} \times_{\mathcal{B}^{(\pi p',\mathcal{T})/}} \mathcal{C}^{(p',\mathcal{T})/} \\ \downarrow & & \downarrow & & \downarrow \\ \mathcal{B}^{(\overline{q},\mathcal{T})/} & \xleftarrow{=} & \mathcal{B}^{(\overline{q},\mathcal{T})/} & \xrightarrow{\chi} & \mathcal{B}^{(\overline{q}',\mathcal{T})/} \end{array}$$

where all the maps are obvious (except possibly χ, which is induced by precomposition by $\mathcal{K}^{\underline{\rhd}} \longrightarrow \mathcal{T}^{\mathrm{op}} \longrightarrow \mathcal{K}^{\underline{\rhd}}$). We claim that ψ and ϕ are equivalences. For ψ, by Lemma 5.4(2),

$$\mathcal{C}^{(h,\mathcal{T})/} \longrightarrow \mathcal{B}^{(\pi h,\mathcal{T})/} \times_{\mathcal{B}^{(\pi p,\mathcal{T})/}} \mathcal{C}^{(p,\mathcal{T})/}$$

is a trivial fibration. But ψ is a pullback of this map, hence an equivalence. For ϕ, note that the $\mathcal{T}$-functors $\mathcal{K}^{\underline{\rhd}} \longrightarrow \mathcal{T}^{\mathrm{op}} \longrightarrow \mathcal{K}^{\underline{\rhd}}$ and $\mathcal{K} \times \{1\} \longrightarrow \mathcal{K} \times \Delta^1$ are both fiberwise cofinal. Hence by [Sha21, Thm. 6.7], we deduce that ϕ is an equivalence.

Replacing p and $\overline{q}$ by p' and $\overline{q}'$, we find ourselves in the situation of Lemma 5.6, which immediately applies given our hypotheses. □

6. Relative parametrized left Kan extensions

6.1. **Definition.** Suppose we have a commutative diagram of $\mathcal{T}$-∞-categories

$$\begin{array}{ccc} \mathcal{C} & \xrightarrow{F} & \mathcal{E} \\ {\scriptstyle i}\big\downarrow & \overset{G}{\nearrow} & \big\downarrow{\scriptstyle \pi} \\ \mathcal{D} & \longrightarrow & \mathcal{B} \end{array}$$

in which i is the inclusion of a full $\mathcal{T}$-subcategory. Then we say that G is a π-$\mathcal{T}$-*left Kan extension of* F if for every $x \in \mathcal{D}_t$, the commutative diagram

$$\begin{array}{ccc} \mathcal{C}^{/\underline{x}} & \xrightarrow{F^x} & \mathcal{E}_{\underline{t}} \\ \big\downarrow & \overset{G^x}{\nearrow} & \big\downarrow{\scriptstyle \pi_{\underline{t}}} \\ (\mathcal{C}^{/\underline{x}})^{\underline{\triangleright}} & \longrightarrow & \mathcal{B}_{\underline{t}} \end{array}$$

exhibits G^x (defined in Construction 2.11) as a $\pi_{\underline{t}}$-$\mathcal{T}^{/t}$-colimit diagram. Here, the lower horizontal $\mathcal{T}^{/t}$-functor is the composite

$$(\mathcal{C}^{/\underline{x}})^{\underline{\triangleright}} \longrightarrow (\mathcal{D}^{/\underline{x}})^{\underline{\triangleright}} \xrightarrow{\theta_x} \mathcal{D}_{\underline{t}} \longrightarrow \mathcal{B}_{\underline{t}}.$$

We also say that G is a *weak* π-$\mathcal{T}$-*left Kan extension of* F if in the pulled-back diagram

$$\begin{array}{ccc} \mathcal{C} & \xrightarrow{F'} & \mathcal{E} \times_{\mathcal{B}} \mathcal{D} \\ {\scriptstyle i}\big\downarrow & \overset{G'}{\nearrow} & \big\downarrow{\scriptstyle \pi'} \\ \mathcal{D} & \xrightarrow{=} & \mathcal{D}, \end{array}$$

G' is a π'-$\mathcal{T}$-left Kan extension of F'.

We may now prove our main existence result on relative $\mathcal{T}$-left Kan extensions, from which Theorem A is an immediate corollary.

6.2. **Theorem.** *Let $\pi : \mathcal{E} \longrightarrow \mathcal{B}$ be a $\mathcal{T}$-cocartesian fibration*[22]*, let $\rho : \mathcal{D} \longrightarrow \mathcal{B}$ be a $\mathcal{T}$-functor, and let $i : \mathcal{C} \subset \mathcal{D}$ be the inclusion of a full $\mathcal{T}$-subcategory.*

(1) Let $F : \mathcal{C} \longrightarrow \mathcal{E}$ be a $\mathcal{T}$-functor over $\mathcal{B}$ and suppose that for all $x \in \mathcal{D}_t$, $F^x : \mathcal{C}^{/\underline{x}} \longrightarrow \mathcal{E}_{\underline{t}}$ admits a $\pi_{\underline{t}}$-$\mathcal{T}^{/t}$-colimit. Then F admits an essentially unique π-$\mathcal{T}$-left Kan extension $G : \mathcal{D} \longrightarrow \mathcal{E}$.

(2) The partial $\mathcal{T}$-left adjoint $i_!$ to the restriction $\mathcal{T}$-functor

$$i^* : \underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{D}, \mathcal{E}) \longrightarrow \underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C}, \mathcal{E})$$

is defined on all those $F : \mathcal{C}_{\underline{t}} \longrightarrow \mathcal{E}_{\underline{t}}$ that admit a weak $\pi_{\underline{t}}$-$\mathcal{T}^{/t}$-left Kan extension G, in which case $i_! F \simeq G$.

Proof. The overarching strategy is the same as in the proof of Theorem 2.13 given in [Sha21, §10]. The key idea is to factor i through the free $\mathcal{T}$-cocartesian fibration as

$$\mathcal{C} \xrightarrow{\iota} \mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{D}) \xrightarrow{\mathrm{ev}_1} \mathcal{D}.$$

(1): Choose a section ξ of the trivial fibration $\mathrm{Ar}_{\mathcal{T}}^{cocart}(\mathcal{E}) \longrightarrow \mathcal{E} \times_{\mathcal{B}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{B})$ that restricts to the identity section on $\mathcal{E}$ and let F' be the composite

$$\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{D}) \xrightarrow{F \times \mathrm{Ar}_{\mathcal{T}}(\rho)} \mathcal{E} \times_{\mathcal{B}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{B}) \xrightarrow{\xi} \mathrm{Ar}_{\mathcal{T}}^{cocart}(\mathcal{E}) \xrightarrow{\mathrm{ev}_1} \mathcal{E}.$$

We then have a commutative diagram

$$\begin{array}{ccc} \mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{D}) & \xrightarrow{F'} & \mathcal{E} \\ {\scriptstyle j}\big\downarrow & & \big\downarrow{\scriptstyle \pi} \\ (\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{D})) \star_{\mathcal{D}} \mathcal{D} & \longrightarrow & \mathcal{B} \end{array}$$

[22]Because of this assumption, our theorem is slightly weaker than [Lur09, Thm. 4.3.2.15] in the case where $\mathcal{T} = \Delta^0$.

where $F = F'|_{\mathcal{C}}$. Note that if $\xi : \mathcal{M} \longrightarrow \mathcal{D}$ is any $\mathcal{T}$-cocartesian fibration, then for any $x \in \mathcal{D}_t$ we have a pullback square

$$\begin{array}{ccc} \mathcal{M}_{\underline{x}} & \longrightarrow & \mathcal{M}^{/\underline{x}} := \mathcal{M} \times_{\mathcal{M} \star_{\mathcal{D}} \mathcal{D}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{M} \star_{\mathcal{D}} \mathcal{D}) \times_{\mathcal{M} \star_{\mathcal{D}} \mathcal{D}} \underline{x} \\ \downarrow & & \downarrow \\ \underline{x} & \xrightarrow{\iota_x} & \mathcal{D}^{/\underline{x}} := \mathrm{Ar}_{\mathcal{T}}(\mathcal{D}) \times_{\mathcal{D}} \underline{x} \end{array}$$

where the righthand vertical functor is a cocartesian fibration (induced by $\mathcal{M} \star_{\mathcal{D}} \mathcal{D} \longrightarrow \mathcal{D}$). Since cocartesian fibrations are smooth [Lur09, Prop. 4.1.2.15] and ι_x is fiberwise cofinal, it follows that $\mathcal{M}_{\underline{x}} \longrightarrow \mathcal{M}^{/\underline{x}}$ is fiberwise cofinal (with respect to the base $(\mathcal{T}^{/t})^{\mathrm{op}}$). In our situation, $\mathcal{M} = \mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{D})$, $\mathcal{M}_{\underline{x}} \cong \mathcal{C}^{/\underline{x}}$, and $(F')^x$ restricts on $\mathcal{C}^{/\underline{x}}$ to F^x. By the proof of Proposition 5.8 together with [Sha21, Thm. 6.7], we see that F^x admits a π-$\mathcal{T}$-colimit if and only if $(F')^x$ admits a π-$\mathcal{T}$-colimit. We thereby reduce to the '$\mathcal{D}$-parametrized' situation of a $\mathcal{T}$-cocartesian fibration $\phi : \mathcal{M} \longrightarrow \mathcal{D}$ and a commutative diagram

$$\begin{array}{ccc} \mathcal{M} & \xrightarrow{F} & \mathcal{E} \\ {\scriptstyle j}\downarrow & \overset{G}{\nearrow} & \downarrow{\scriptstyle \pi} \\ \mathcal{M} \star_{\mathcal{D}} \mathcal{D} & \longrightarrow & \mathcal{B} \end{array}$$

in which F sends ϕ-cocartesian edges to π-cocartesian edges. Pulling back along ρ, we may also suppose that $\mathcal{D} = \mathcal{B}$, noting that the discrepancy between strong and weak π-$\mathcal{T}$-left Kan extensions will lie only in the pointwise property of the eventual extension and does not feature in the constructive proof of existence.

We may solve the coherence problem of assembling the individual $\pi_{\underline{t}}$-$\mathcal{T}^{/t}$-colimits together into a π-$\mathcal{T}$-left Kan extension G by a similar method to the proof of [Sha21, Thm. 9.15]. Consider [Sha21, Constr. 9.8] applied to ϕ and F; this yields

$$\mathcal{W} = \mathcal{E}^{(\phi,F)/\mathcal{T}} := \mathcal{D} \times_{\widetilde{\mathrm{Fun}}_{\mathcal{D},\mathcal{T}}(\mathcal{M},\mathcal{E})} \widetilde{\mathrm{Fun}}_{\mathcal{D},\mathcal{T}}(\mathcal{M} \star_{\mathcal{D}} \mathcal{D}, \mathcal{E}),$$

such that for $x \in \mathcal{D}_t$, if we let $F|_x : \mathcal{M}_{\underline{x}} \longrightarrow \mathcal{E}_{\underline{x}}$ denote the $\mathcal{T}^{/t}$-functor given by restriction, then the parametrized fiber $\mathcal{W}_{\underline{x}}$ is equivalent to $(\mathcal{E}_{\underline{x}})^{(F|_x,\mathcal{T}^{/t})/}$ by Corollary 4.6 (or [Sha21, Cor. 9.9]). Let $\mathcal{W}' \subset \mathcal{W}$ be the full $\mathcal{T}$-subcategory spanned by the $\mathcal{T}^{/t}$-colimit diagrams $(\mathcal{M}_{\underline{x}})^{\underline{\triangleright}} \longrightarrow \mathcal{E}_{\underline{x}}$, so that for all $x \in \mathcal{D}$, the fiber $\mathcal{W}'_x$ is that spanned by the initial objects in $\mathcal{W}_x$, which are precisely weak $\pi_{\underline{t}}$-$\mathcal{T}^{/t}$-colimit diagrams extending $F|_x$. Note that the use of [Sha21, Prop. 9.10] and [Sha21, Lem. 9.11] in the proof of [Sha21, Thm. 9.15] won't apply here since $\mathcal{E} \longrightarrow \mathcal{D}$ isn't supposed to be a $\mathcal{T}$-cartesian fibration. However, we may argue directly that $\mathcal{W}' \longrightarrow \mathcal{D}$ is a trivial fibration by computing mapping spaces as follows:

(∗) For any $\alpha : x \longrightarrow y \in \mathcal{D}_t$ and extensions $\overline{F|_i}$ of $F|_i$ over $(\mathcal{M}_{\underline{i}})^{\underline{\triangleright}}$, $i \in \{x, y\}$, we have that maps $\overline{F|_x} \longrightarrow \overline{F|_y}$ in $\widetilde{\mathrm{Fun}}_{\mathcal{D},\mathcal{T}}(\mathcal{M} \star_{\mathcal{D}} \mathcal{D}, \mathcal{E})$ are defined by lax commutative squares of $\mathcal{T}^{/t}$-functors

$$\begin{array}{ccc} (\mathcal{M}_{\underline{x}})^{\underline{\triangleright}} & \xrightarrow{\overline{F|_x}} & \mathcal{E}_{\underline{x}} \\ {\scriptstyle \alpha_!}\downarrow & \swarrow & \downarrow{\scriptstyle \alpha_!} \\ (\mathcal{M}_{\underline{y}})^{\underline{\triangleright}} & \xrightarrow[\overline{F|_y}]{} & \mathcal{E}_{\underline{y}}, \end{array}$$

and hence we have

$$\mathrm{Map}_{\mathcal{W}}(\overline{F|_x}, \overline{F|_y}) \simeq \mathrm{Map}(\alpha_! \overline{F|_x}, \overline{F|_y} \alpha_!) \times_{\mathrm{Map}(\alpha_! F|_x, F|_y \alpha_!)} \{\mathrm{id}\}.$$

By assumption, if $\overline{F|_x}$ is a $\mathcal{T}^{/t}$-colimit diagram, then $\alpha_! \overline{F|_x}$ is as well. Therefore, $\mathrm{Map}_{\mathcal{W}'}(\overline{F|_x}, \overline{F|_y})$ is contractible for all $\mathcal{T}^{/t}$-colimit diagrams $\overline{F|_x}$ and $\overline{F|_y}$, and this suffices to show that $\mathcal{W}' \longrightarrow \mathcal{D}$ is a trivial fibration since we already have compatibility of these initial objects with restriction in the base $\mathcal{T}$. Furthermore, any section τ of this trivial fibration defines a relative left adjoint of $\mathcal{W} \longrightarrow \mathcal{D}$ with respect to the base $\mathcal{D}$.

Now by Theorem 4.9, applying $\underline{\mathrm{Fun}}_{/\mathcal{D},\mathcal{T}}(\mathcal{D}, -)$ to τ yields an extension $G : \mathcal{M} \star_{\mathcal{D}} \mathcal{D} \longrightarrow \mathcal{E}$ of F that is a $\mathcal{T}$-initial object of

$$\mathcal{T}^{\mathrm{op}} \times_{\sigma_F, \underline{\mathrm{Fun}}_{/\mathcal{D},\mathcal{T}}(\mathcal{M},\mathcal{E})} \underline{\mathrm{Fun}}_{/\mathcal{D},\mathcal{T}}(\mathcal{M} \star_{\mathcal{D}} \mathcal{D}, \mathcal{E}).$$

Taking cocartesian sections, we then see that G is an initial object in the space of such fillers and is in particular essentially unique.

(2): Let $\phi' : (\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{D})) \star_{\mathcal{D}} \mathcal{D} \longrightarrow \mathcal{D}$ be the structure map. Factor i^* as

$$\underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{D},\mathcal{E}) \xrightarrow{(\phi')^*} \underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}((\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{D})) \star_{\mathcal{D}} \mathcal{D},\mathcal{E}) \xrightarrow{j^*} \underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C} \times_{\mathcal{D}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{D}),\mathcal{E}) \xrightarrow{\iota^*} \underline{\mathrm{Fun}}_{/\mathcal{B},\mathcal{T}}(\mathcal{C},\mathcal{E}).$$

Then since ϕ' is $\mathcal{T}$-left adjoint to $i_{\mathcal{D}}$, $(\phi')^*$ has $\mathcal{T}$-left adjoint $(i_{\mathcal{D}})^*$. Also, by Example 3.8 the procedure $F \mapsto F'$ of (1) defines a fully faithful $\mathcal{T}$-left adjoint to ι^* with essential image spanned by those $\mathcal{T}$-functors that send ϕ-cocartesian edges to π-cocartesian edges. To conclude, we observe that in the proof of (1) we showed that the partial left $\mathcal{T}$-adjoint $j_!$ is defined on F' if it is obtained from F satisfying the assumptions of (2). □

7. More on the parametrized Yoneda embedding

For a $\mathcal{T}$-∞-category $\mathcal{C}$, let $\underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C}) \coloneqq \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{C}^{\mathrm{vop}}, \underline{\mathbf{Spc}}_{\mathcal{T}})$ be the $\mathcal{T}$-∞-category of $\mathcal{T}$-presheaves and $j_{\mathcal{T}} : \mathcal{C} \longrightarrow \underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})$ the $\mathcal{T}$-Yoneda embedding [Sha21, §11]. In this section, we record a generalization (Proposition 7.5) of our earlier result that $j_{\mathcal{T}}$ strongly preserves $\mathcal{T}$-limits [Sha21, Cor. 11.10] as well as some basic facts concerning $\mathcal{T}$-corepresentable $\mathcal{T}$-left fibrations (Lemma 7.8) that mirror the discussion in [Lur09, §4.4.4]. These results play a technical role in the remainder of the paper and so their proofs could be skipped on a first reading.

7.1. **Lemma.** *Let $\mathcal{K}$ and $\mathcal{C}$ be $\mathcal{T}$-∞-categories. Then we have a homotopy pullback square*

$$\begin{array}{ccc} \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K}^{\trianglelefteq},\mathcal{C}) & \longrightarrow & \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K} \times \Delta^1,\mathcal{C}) \\ \downarrow & & \downarrow \\ \mathcal{C} \times_{\mathcal{T}^{\mathrm{op}}} \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K},\mathcal{C}) & \longrightarrow & \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K},\mathcal{C}) \times_{\mathcal{T}^{\mathrm{op}}} \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K},\mathcal{C}). \end{array}$$

Thus, for any $\mathcal{T}$-functor $p : \mathcal{K} \longrightarrow \mathcal{C}$ and $t \in \mathcal{T}$, we have an equivalence

$$(\mathcal{C}^{/(p,\mathcal{T})})_t \simeq \mathcal{C}_t \times_{\mathrm{Fun}_{\mathcal{T}^{/t}}(\mathcal{K}_{\underline{t}},\mathcal{C}_{\underline{t}})} \mathrm{Fun}_{\mathcal{T}^{/t}}(\mathcal{K}_{\underline{t}},\mathcal{C}_{\underline{t}})^{/\{p_{\underline{t}}\}}$$

of right fibrations over $\mathcal{C}_t$.

Proof. Consider the commutative square of $\mathcal{T}$-∞-categories

$$\begin{array}{ccc} \mathcal{K} \times \partial\Delta^1 & \longrightarrow & \mathcal{T}^{\mathrm{op}} \coprod \mathcal{K} \\ \downarrow & & \downarrow \\ \mathcal{K} \times \Delta^1 & \longrightarrow & \mathcal{K}^{\trianglelefteq} \end{array}$$

where the vertical maps are the inclusions and the horizontal maps are induced by the structure map $\mathcal{K} \longrightarrow \mathcal{T}^{\mathrm{op}}$ and the identity on $\mathcal{K}$. By application of [Lur09, Prop. 4.2.1.2] fiberwise, this is a homotopy pushout square, and the first claim follows by transforming the pushout to a pullback under $\underline{\mathrm{Fun}}_{\mathcal{T}}(-,\mathcal{C})$. For a $\mathcal{T}$-functor $p : \mathcal{K} \longrightarrow \mathcal{C}$, we thus obtain a commutative diagram of homotopy pullback squares

$$\begin{array}{ccccc} \mathcal{C}^{/(p,\mathcal{T})} & \longrightarrow & \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K},\mathcal{C})^{/(\sigma_p,\mathcal{T})} & \longrightarrow & \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K} \times \Delta^1,\mathcal{C}) \\ \downarrow & & \downarrow & & \downarrow \\ \mathcal{C} & \xrightarrow{\delta} & \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K},\mathcal{C}) & \xrightarrow{(\mathrm{id},\sigma_p)} & \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K},\mathcal{C}) \times_{\mathcal{T}^{\mathrm{op}}} \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K},\mathcal{C}), \end{array}$$

where $\sigma_p : \mathcal{T}^{\mathrm{op}} \longrightarrow \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K},\mathcal{C})$ selects p. To identify $(\mathcal{C}^{/(p,\mathcal{T})})_t$, after replacing p by $p_{\underline{t}}$ we may suppose that $\mathcal{T}$ has a final object $*$. But then for any $\mathcal{T}$-∞-category $\mathcal{D}$ and cocartesian section $\sigma : \mathcal{T}^{\mathrm{op}} \longrightarrow \mathcal{D}$ that selects an object $x = \sigma(*) \in \mathcal{D}_*$, we have that $(\mathcal{D}^{/(\sigma,\mathcal{T})})_* \simeq (\mathcal{D}_*)^{/x}$ by [Sha21, Prop. 4.30]. □

The following lemma generalizes and supplies another proof of the fact that the Yoneda embedding preserves limits [Lur09, Prop. 5.1.3.2].

7.2. **Lemma.** *Let $p : \mathcal{K} \longrightarrow \mathcal{C}$ be functor of small ∞-categories. Then the commutative square of ∞-categories*

$$\begin{array}{ccc} \mathcal{C}^{/p} & \longrightarrow & \mathbf{P}(\mathcal{C})^{/jp} \\ \downarrow & & \downarrow \\ \mathcal{C} & \xrightarrow{j} & \mathbf{P}(\mathcal{C}) \end{array}$$

is a homotopy pullback square. Consequently, the functor $\varphi : \mathcal{C}^{\mathrm{op}} \longrightarrow \mathbf{Spc}$ classifying the right fibration $\mathcal{C}^{/p} \longrightarrow \mathcal{C}$ is canonically equivalent to $\lim_{\mathcal{K}} jp$.

Proof. It suffices to show that the induced functor $\psi : \mathcal{C}^{/p} \longrightarrow \mathcal{C} \times_{\mathbf{P}(\mathcal{C})} \mathbf{P}(\mathcal{C})^{/jp}$ is an equivalence of right fibrations over $\mathcal{C}$ by checking that for all $x \in \mathcal{C}$, ψ_x is an equivalence. First note that by the $\mathcal{T} = \Delta^0$ case of Lemma 7.1, we may identify ψ_x with the map

$$\psi'_x : \mathrm{Map}_{\mathcal{C}^{\mathcal{K}}}(\delta x, p) \longrightarrow \mathrm{Map}_{\mathbf{P}(\mathcal{C})^{\mathcal{K}}}(\delta j(x), jp) \simeq \mathrm{Map}_{\mathbf{P}(\mathcal{C})}(j(x), \lim_{\mathcal{K}} jp) \simeq (\lim_{\mathcal{K}} jp)(x)$$

induced by postcomposition by the Yoneda embedding. Using the end formula for mapping spaces in $\mathrm{Fun}(\mathcal{K}, \mathcal{C})$ [Gla16, Prop. 2.3], we have an equivalence

$$\mathrm{Map}_{\mathcal{C}^{\mathcal{K}}}(\delta x, p) \simeq \int_{\mathcal{K}} \mathrm{Map}_{\mathcal{C}}(x, p(-)) := \lim_{\mathrm{Tw}(\mathcal{K})} \mathrm{Map}_{\mathcal{C}}(x, p(-)).$$

where the limit is taken over the functor

$$\mathrm{Tw}(\mathcal{K}) \xrightarrow{\mathrm{ev}_1} \mathcal{K} \xrightarrow{p} \mathcal{C} \xrightarrow{\mathrm{Map}_{\mathcal{C}}(x,-)} \mathbf{Spc}.$$

Under this identification, ψ'_x is induced by restriction along ev_1 (using the contravariant functoriality of limits in the diagram). The claim then follows from Lemma 7.3.

Since representable right fibrations are classified by the corresponding representable functor [Lur09, Prop. 4.4.4.5], we then have that φ is equivalent to the composition

$$\mathcal{C}^{\mathrm{op}} \xrightarrow{j^{\mathrm{op}}} \mathbf{P}(\mathcal{C})^{\mathrm{op}} \xrightarrow{\mathrm{Map}_{\mathbf{P}(\mathcal{C})}(-, \lim_{\mathcal{K}} jp)} \mathbf{Spc}.$$

An argument with the Yoneda lemma then shows φ is in turn equivalent to $\lim_{\mathcal{K}} jp$ (in more detail, see Remark 7.4). □

7.3. **Lemma.** *Let $\mathcal{K}$ be an ∞-category. Then the source and target functors*

$$\mathrm{ev}_0, \mathrm{ev}_1 : \mathrm{Tw}(\mathcal{K}) \longrightarrow \mathcal{K}$$

are right cofinal.

Proof. We verify the hypotheses of Joyal's cofinality theorem [Lur09, Thm. 4.1.3.1] for ev_1 (in its opposite formulation). Let $y \in \mathcal{K}$ and consider the commutative diagram of homotopy pullbacks

$$\begin{array}{ccccc} (\mathcal{K}_{/y})^{\mathrm{op}} & \xrightarrow{\iota'} & \mathrm{Tw}(\mathcal{K}) \times_{\mathcal{K}} \mathcal{K}_{/y} & \longrightarrow & \mathrm{Tw}(\mathcal{K}) \\ \downarrow & & \downarrow & & \downarrow{\scriptstyle \mathrm{ev}_1} \\ \{y\} & \xrightarrow{\iota} & \mathcal{K}_{/y} & \longrightarrow & \mathcal{K} \end{array}$$

Since ev_1 is a left fibration, ev_1 is a smooth map [Lur09, Prop. 4.1.2.15]. Therefore, the pullback ι' of the cofinal inclusion ι along ev_1 is again cofinal, so in particular a weak homotopy equivalence. We deduce that $\mathrm{Tw}(\mathcal{K}) \times_{\mathcal{K}} \mathcal{K}_{/y}$ is weakly contractible, which proves the claim. The proof for ev_0 is similar. □

7.4. **Remark.** Let $q \in \mathbf{P}(\mathcal{C})$ be a presheaf. By [Lur09, Lem. 5.1.5.2], we have an equivalence $q(c) \simeq \mathrm{Map}_{\mathbf{P}(\mathcal{C})}(j(c), q)$ of spaces for all $c \in \mathcal{C}$. We can promote this to an equivalence of presheaves

$$\mathrm{Map}_{\mathbf{P}(\mathcal{C})}(j(-), q) \simeq q(-)$$

as follows. Let $\pi : \mathcal{C}^{/q} = \mathcal{C} \times_{\mathbf{P}(\mathcal{C})} \mathbf{P}(\mathcal{C})^{/q} \longrightarrow \mathcal{C}$ denote the projection. We then have the sequence of equivalences in $\mathbf{P}(\mathcal{C})$

$$\begin{aligned} q(-) &\simeq \mathrm{colim}_{\mathcal{C}^{/q}} \mathrm{Map}_{\mathcal{C}}(-, \pi) \simeq \mathrm{colim}_{\mathcal{C}^{/q}} \mathrm{Map}_{\mathbf{P}(\mathcal{C})}(j(-), j\pi) \\ &\simeq \mathrm{Map}_{\mathbf{P}(\mathcal{C})}(j(-), \mathrm{colim}_{\mathcal{C}^{/q}} j\pi) \simeq \mathrm{Map}_{\mathbf{P}(\mathcal{C})}(j(-), q), \end{aligned}$$

where we use that $\mathrm{id}_{\mathbf{P}(\mathcal{C})}$ is the left Kan extension of j along itself [Lur09, Lem. 5.1.5.3] for the first and last equivalences, j is fully faithful [Lur09, Prop. 5.1.3.1] for the second equivalence, and $j(c)$ corepresents evaluation at c [Lur09, Lem. 5.1.5.2] (and is hence completely compact) to show the third equivalence, where the map in question is the canonical colimit interchange map.

Now suppose $\mathcal{C}$ is a $\mathcal{T}$-∞-category and let $q \in \mathbf{P}_{\mathcal{T}}(\mathcal{C}) \simeq \mathbf{P}(\mathcal{C}^{\mathrm{v}})$ be a $\mathcal{T}$-presheaf. We again have that the $\mathcal{T}$-Yoneda embedding $j_{\mathcal{T}} : \mathcal{C} \longrightarrow \underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})$, given fiberwise by $\mathcal{C}_t \subset \mathbf{P}(\mathcal{C}_t) \subset \mathbf{P}_{\mathcal{T}^{/t}}(\mathcal{C}) \simeq \mathbf{P}(\mathcal{C}_{\underline{t}}^{\mathrm{v}})$, is $\mathcal{T}$-fully faithful, $\mathrm{id}_{\underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})}$ is the $\mathcal{T}$-left Kan extension of $j_{\mathcal{T}}$ along itself [Sha21, Lem. 11.1], and for any $c \in \mathcal{C}_t$, $j_{\mathcal{T}}(c)$ is completely compact as an object in $\mathbf{P}_{\mathcal{T}^{/t}}(\mathcal{C}_{\underline{t}}) \simeq \mathbf{P}(\mathcal{C}_{\underline{t}}^{\mathrm{v}})$, hence $\mathcal{T}^{/t}$-completely compact in $\underline{\mathbf{P}}_{\mathcal{T}^{/t}}(\mathcal{C}_{\underline{t}})$ since $\mathcal{T}$-colimits in $\underline{\mathbf{Spc}}_{\mathcal{T}}$ are computed as ordinary colimits under the correspondence of [Sha21, Prop. 5.5]. Repeating the above argument then shows that we have an equivalence of $\mathcal{T}$-presheaves

$$q(-) \simeq \underline{\mathrm{Map}}_{\underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})}(j_{\mathcal{T}}(-), q) : \mathcal{C}^{\mathrm{vop}} \longrightarrow \mathbf{Spc},$$

where on the right we view q as a cocartesian section of $\underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})$.

7.5. **Proposition.** *Let $p : \mathcal{K} \longrightarrow \mathcal{C}$ be a $\mathcal{T}$-functor of small $\mathcal{T}$-∞-categories. Then the commutative square of $\mathcal{T}$-∞-categories*

$$\begin{array}{ccc} \mathcal{C}^{/(p,\mathcal{T})} & \longrightarrow & \underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})^{/(j_{\mathcal{T}}p,\mathcal{T})} \\ \downarrow & & \downarrow \\ \mathcal{C} & \xrightarrow{j_{\mathcal{T}}} & \underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C}) \end{array}$$

is a homotopy pullback square. Consequently, the functor $\mathcal{C}^{\mathrm{vop}} \longrightarrow \mathbf{Spc}$ classifying the left fibration

$$(\mathcal{C}^{/(p,\mathcal{T})})^{\mathrm{vop}} \simeq (\mathcal{C}^{\mathrm{vop}})^{(p^{\mathrm{vop}},\mathcal{T})/} \longrightarrow \mathcal{C}^{\mathrm{vop}}$$

is canonically equivalent to $\lim^{\mathcal{T}}_{\mathcal{K}} j_{\mathcal{T}} p$.

Proof. The square in question is a homotopy pullback if and only if for all $t \in \mathcal{T}$, the square

$$\begin{array}{ccc} (\mathcal{C}^{/(p,\mathcal{T})})_t \simeq (\mathcal{C}_{\underline{t}}^{/(p_{\underline{t}},\mathcal{T}^{/t})})_{\mathrm{id}_t} & \longrightarrow & (\underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})^{/(j_{\mathcal{T}}p,\mathcal{T})})_t \simeq (\mathbf{P}_{\mathcal{T}^{/t}}(\mathcal{C}_{\underline{t}})^{/(p_{\underline{t}},\mathcal{T}^{/t})})_{\mathrm{id}_t} \\ \downarrow & & \downarrow \\ \mathcal{C}_t \simeq (\mathcal{C}_{\underline{t}})_{\mathrm{id}_t} & \longrightarrow & \underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})_t \simeq \mathbf{P}_{\mathcal{T}^{/t}}(\mathcal{C}_{\underline{t}}) \end{array}$$

is a homotopy pullback of ∞-categories. Therefore, after replacing $\mathcal{T}$ by $\mathcal{T}^{/t}$, we may suppose that $\mathcal{T}$ has a final object $* \in \mathcal{T}$, and it suffices to check that the square of ∞-categories

$$\begin{array}{ccc} (\mathcal{C}^{/(p,\mathcal{T})})_* & \longrightarrow & (\underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})^{/(j_{\mathcal{T}}p,\mathcal{T})})_* \\ \downarrow & & \downarrow \\ \mathcal{C}_* & \longrightarrow & \mathbf{P}_{\mathcal{T}}(\mathcal{C}) \end{array}$$

is a homotopy pullback. Let π generically denote all pullbacks of the structure map $\mathcal{K} \longrightarrow \mathcal{T}^{\mathrm{op}}$. By the universal property of $\underline{\mathbf{Spc}}_{\mathcal{T}}$ as a $\mathcal{T}$-∞-category of $\mathcal{T}$-objects in $\mathbf{Spc}$ [Sha21, Prop. 3.10], we have an identification of the constant $\mathcal{T}$-diagram functor

$$\mathbf{P}_{\mathcal{T}}(\mathcal{C}) = \mathrm{Fun}_{\mathcal{T}}(\mathcal{C}^{\mathrm{vop}}, \underline{\mathbf{Spc}}_{\mathcal{T}}) \longrightarrow \mathrm{Fun}_{\mathcal{T}}(\mathcal{K}, \underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C}))$$

with the functor

$$\pi^* : \mathrm{Fun}(\mathcal{C}^{\mathrm{vop}}, \mathbf{Spc}) \longrightarrow \mathrm{Fun}(\mathcal{C}^{\mathrm{vop}} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{K}, \mathbf{Spc})$$

given by restriction along π. Abusing notation, let $j_{\mathcal{T}}p$ also denote the corresponding functor $\mathcal{C}^{\mathrm{vop}} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{K} \longrightarrow \mathbf{Spc}$ under this equivalence. Then by Lemma 7.1, we have a homotopy pullback square

$$\begin{array}{ccc} (\underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})^{/(j_{\mathcal{T}}p,\mathcal{T})})_* & \longrightarrow & \mathrm{Fun}(\mathcal{C}^{\mathrm{vop}} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{K}, \mathbf{Spc})^{/j_{\mathcal{T}}p} \\ \downarrow & & \downarrow \\ \mathbf{P}_{\mathcal{T}}(\mathcal{C}) \simeq \mathbf{P}(\mathcal{C}^{\mathrm{v}}) & \xrightarrow{\pi^*} & \mathrm{Fun}(\mathcal{C}^{\mathrm{vop}} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{K}, \mathbf{Spc}). \end{array}$$

By the $S = \Delta^0$ case of [Sha21, Lem. 8.8] applied to the adjunction $\pi^* \dashv \pi_*$, we deduce an equivalence

$$(\underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})^{/(j_{\mathcal{T}}p,\mathcal{T})})_* \simeq \mathbf{P}(\mathcal{C}^{\mathrm{v}})^{/\pi_*(j_{\mathcal{T}}p)}.$$

Next, consider the functor

$$P' = P \times \mathrm{id}_{\mathcal{K}} : \mathcal{C}_*^{\mathrm{op}} \times \mathcal{K} \cong (\mathcal{C}_*^{\mathrm{op}} \times \mathcal{T}^{\mathrm{op}}) \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{K} \longrightarrow \mathcal{C}^{\mathrm{vop}} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{K},$$

defined to be the product of the unique $\mathcal{T}$-functor $P : \mathcal{C}_*^{\mathrm{op}} \times \mathcal{T}^{\mathrm{op}} \longrightarrow \mathcal{C}^{\mathrm{vop}}$ extending the inclusion $\iota : \mathcal{C}_*^{\mathrm{op}} \subset \mathcal{C}^{\mathrm{vop}}$ on the first factor and the identity on $\mathcal{K}$ on the second factor; informally, $P'(c,k) = (\chi_t^*(c), k)$ for $k \in \mathcal{K}_t$ and $\chi_t : t \longrightarrow *$ the unique map. Using the canonical unit transformation $\iota \Rightarrow P$, P' fits into a lax commutative diagram

$$\begin{array}{ccc} \mathcal{C}_*^{\mathrm{op}} \times \mathcal{K} & \xrightarrow{P'} & \mathcal{C}^{\mathrm{vop}} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{K} \\ \downarrow{\scriptstyle \mathrm{pr}} & \nearrow & \downarrow{\scriptstyle \pi} \\ \mathcal{C}_*^{\mathrm{op}} & \xrightarrow{\iota} & \mathcal{C}^{\mathrm{vop}}. \end{array}$$

We claim that the induced map $\theta : \iota^* \pi_*(j_{\mathcal{T}}p) \longrightarrow \mathrm{pr}_* P'^*(j_{\mathcal{T}}p)$ is an equivalence, which we may check objectwise at each $c \in \mathcal{C}_*$. Let $\underline{c} : \mathcal{T}^{\mathrm{op}} \longrightarrow \mathcal{C}^{\mathrm{vop}}$ denote the unique $\mathcal{T}$-functor such that $\underline{c}(*) = c$. Since $\mathcal{T}$-limits in $\mathcal{T}$-functor categories are computed pointwise (by the dual of [Sha21, Prop. 9.17]), under the equivalences of [Sha21, Prop. 3.10] we have a commutative square

$$\begin{array}{ccc} \mathrm{Fun}(\mathcal{C}^{\mathrm{vop}} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{K}, \mathbf{Spc}) & \xrightarrow{\underline{c}^*} & \mathrm{Fun}(\mathcal{K}, \mathbf{Spc}) \\ \downarrow{\scriptstyle \pi_*} & & \downarrow{\scriptstyle \pi_*} \\ \mathrm{Fun}(\mathcal{C}^{\mathrm{vop}}, \mathbf{Spc}) & \xrightarrow{\underline{c}^*} & \mathrm{Fun}(\mathcal{T}^{\mathrm{op}}, \mathbf{Spc}) \end{array}$$

where the vertical functors are given by right Kan extension and the horizontal functors by restriction, and after evaluation at $* \in \mathcal{T}^{\mathrm{op}}$ this equivalence identifies with $\theta(c)$, which proves the claim.

Abusing notation, let jp also denote its adjoint $\mathcal{K} \times \mathcal{C}^{\mathrm{op}} \longrightarrow \mathbf{Spc}$, and observe that $(P')^*(j_t p) \simeq (jp)|_{\mathcal{K} \times \mathcal{C}_*^{\mathrm{op}}}$, so that the equivalence θ yields an equivalence

$$\mathbf{P}(\mathcal{C}_*)^{/(\pi_*(j_{\mathcal{T}}p))|_{\mathcal{C}_*^{\mathrm{op}}}} \simeq \mathbf{P}(\mathcal{C}_*)^{/\mathrm{pr}_*((jp)|_{\mathcal{K} \times \mathcal{C}_*^{\mathrm{op}}})}.$$

Using that pr is a cartesian fibration, we have an equivalence $\mathrm{pr}_*((jp)|_{\mathcal{K} \times \mathcal{C}_*^{\mathrm{op}}}) \simeq (\mathrm{pr}_*(jp))|_{\mathcal{C}_*^{\mathrm{op}}}$. Note that the limit of $jp : \mathcal{K} \longrightarrow \mathbf{P}(\mathcal{C})$ is computed by $\mathrm{pr}_*(jp)$, so $\mathbf{P}(\mathcal{C})^{/jp} \simeq \mathbf{P}(\mathcal{C})^{/\mathrm{pr}_*(jp)}$. Using that $\mathcal{C}_* \longrightarrow \mathbf{P}_{\mathcal{T}}(\mathcal{C}) \simeq \mathbf{P}(\mathcal{C}^{\mathrm{v}})$ factors through $\mathbf{P}(\mathcal{C}_*)$ and invoking [Sha21, Lem. 8.8] with respect to the adjunctions $\mathbf{P}(\mathcal{C}_*) \rightleftarrows \mathbf{P}(\mathcal{C}^{\mathrm{v}})$ and $\mathbf{P}(\mathcal{C}_*) \rightleftarrows \mathbf{P}(\mathcal{C})$, we then reduce the claim to checking that the outer square

$$\begin{array}{ccccc} (\mathcal{C}^{/(p,\mathcal{T})})_* & \longrightarrow & \mathbf{P}(\mathcal{C}_*)^{/(jp)|_{\mathcal{C}_*^{\mathrm{op}}}} & \longrightarrow & \mathbf{P}(\mathcal{C})^{/jp} \\ \downarrow & & \downarrow & & \downarrow \\ \mathcal{C}_* & \longrightarrow & \mathbf{P}(\mathcal{C}_*) & \longrightarrow & \mathbf{P}(\mathcal{C}). \end{array}$$

is a homotopy pullback square. But this follows from Lemma 7.6 and Lemma 7.2.

The last statement then follows from [Sha21, Prop. 5.24], Lemma 7.8(3), and Remark 7.4. □

7.6. **Lemma.** *Suppose $\mathcal{T}$ has a final object $*$ and let $p : \mathcal{K} \longrightarrow \mathcal{C}$ be a $\mathcal{T}$-functor. Then we have a homotopy pullback square*

$$\begin{array}{ccc} (\mathcal{C}^{/(p,\mathcal{T})})_* & \longrightarrow & \mathcal{C}^{/p} \\ \downarrow & & \downarrow \\ \mathcal{C}_* & \longrightarrow & \mathcal{C}. \end{array}$$

Proof. Note that the inclusion of the initial object $\Delta^0 \longrightarrow (\mathcal{T}^{\mathrm{op}})^\sharp$ is a cocartesian equivalence in $s\mathbf{Set}^+_{/\mathcal{T}^{\mathrm{op}}}$. By [Sha21, Thm. 4.16], $i : \Delta^0 \star_{\mathcal{T}^{\mathrm{op}}} {}_\natural\mathcal{K} \longrightarrow {}_\natural\mathcal{K}^{\trianglelefteq}$ is a cocartesian equivalence. Since $\mathrm{Fun}_{\mathcal{T}}(-,-)$ is a Quillen bifunctor, precomposition by i then yields a homotopy pullback square

$$\begin{array}{ccc} \mathrm{Fun}_{\mathcal{T}}(\mathcal{K}^{\underline{\lhd}}, \mathcal{C}) & \longrightarrow & \mathrm{Fun}(\mathcal{K}^{\lhd}, \mathcal{C}) \\ \downarrow & & \downarrow \\ \mathcal{C}_* \times \mathrm{Fun}_{\mathcal{T}}(\mathcal{K}, \mathcal{C}) & \longrightarrow & \mathcal{C} \times \mathrm{Fun}(\mathcal{K}, \mathcal{C}) \end{array}$$

where the bottom horizontal functor is the evident inclusion. Taking the pullback over $\{p\}$ then produces the desired homotopy pullback square. □

We have the evident parametrized analogue of a (co)representable fibration.

7.7. **Definition.** Let $f : \mathcal{D} \longrightarrow \mathcal{C}$ be a $\mathcal{T}$-left resp. $\mathcal{T}$-right fibration. If $\mathcal{D}$ admits a $\mathcal{T}$-initial object resp. $\mathcal{T}$-final object, then we say that f is $\mathcal{T}$-*corepresentable* resp. $\mathcal{T}$-*representable*.

We record some basic facts about $\mathcal{T}$-corepresentable $\mathcal{T}$-left fibrations and the $\mathcal{T}$-Yoneda embedding.

7.8. **Lemma.** *(1) Let $\mathcal{D}$ be a $\mathcal{T}$-∞-category and let $\sigma : \mathcal{T}^{\mathrm{op}} \longrightarrow \mathcal{D}$ be a cocartesian section. Then σ is a $\mathcal{T}$-initial object of $\mathcal{D}$ if and only if $\mathcal{D}^{(\sigma,\mathcal{T})/} \longrightarrow \mathcal{D}$ is a trivial fibration.*

(2) Let $f : \mathcal{D} \longrightarrow \mathcal{C}$ be a $\mathcal{T}$-functor. If f is a $\mathcal{T}$-corepresentable $\mathcal{T}$-left fibration with $\mathcal{T}$-initial object σ, then we have a canonical equivalence $\mathcal{D} \simeq \mathcal{C}^{(f\sigma,\mathcal{T})/}$ of $\mathcal{T}$-∞-categories over $\mathcal{C}$.

(3) Let $\sigma : \mathcal{T}^{\mathrm{op}} \longrightarrow \mathcal{C}$ be any cocartesian section. The $\mathcal{T}$-left fibration $\mathcal{C}^{(\sigma,\mathcal{T})/} \longrightarrow \mathcal{C}$, as a left fibration, is classified by the functor

$$\underline{\mathrm{Map}}_{\mathcal{C}}(\sigma, -) : \mathcal{C} \xrightarrow{(\sigma^{\mathrm{vop}},\mathrm{id})} \mathcal{C}^{\mathrm{vop}} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{C} \xrightarrow{\underline{\mathrm{Map}}_{\mathcal{C}}(-,-)} \mathbf{Spc}$$

that sends $c \in \mathcal{C}_t$ to $\mathrm{Map}_{\mathcal{C}_t}(\sigma(t), c)$.

(4) The functor obtained by taking cocartesian sections of the $\mathcal{T}$-Yoneda embedding $j_{\mathcal{T}}$

$$\widehat{j_{\mathcal{T}}} : \mathrm{Fun}_{\mathcal{T}}(\mathcal{T}^{\mathrm{op}}, \mathcal{C}) \longrightarrow \mathbf{P}_{\mathcal{T}}(\mathcal{C}) \simeq \mathbf{P}(\mathcal{C}^{\mathrm{v}}), \quad \widehat{j_{\mathcal{T}}}(\sigma) \mapsto \underline{\mathrm{Map}}_{\mathcal{C}}(-, \sigma) \simeq \underline{\mathrm{Map}}_{\mathcal{C}^{\mathrm{vop}}}(\sigma^{\mathrm{vop}}, -)$$

is fully faithful. Under the straightening equivalence $\mathbf{P}_{\mathcal{T}}(\mathcal{C}) \simeq \mathbf{LFib}(\mathcal{C}^{\mathrm{vop}})$, $\widehat{j_{\mathcal{T}}}$ has essential image spanned by the $\mathcal{T}$-corepresentable $\mathcal{T}$-left fibrations over $\mathcal{C}^{\mathrm{vop}}$.

(5) The composite $\mathcal{T}$-functor $\underline{\mathrm{colim}}^{\mathcal{T}} j_{\mathcal{T}} : \mathcal{C} \longrightarrow \underline{\mathbf{Spc}}_{\mathcal{T}}$ is constant with value the $\mathcal{T}$-final object of $\underline{\mathbf{Spc}}_{\mathcal{T}}$.

Proof. First note that we have a homotopy pullback square

$$\begin{array}{ccc} \mathrm{Ar}_{\mathcal{T}}(\mathcal{D}) = \mathcal{T}^{\mathrm{op}} \times_{\mathrm{Ar}(\mathcal{T}^{\mathrm{op}})} \mathrm{Ar}(\mathcal{D}) & \xrightarrow{\simeq} & \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{T} \times \Delta^1, \mathcal{D}) \\ \downarrow{\scriptstyle \mathrm{ev}_0} & & \downarrow{\scriptstyle \mathrm{ev}_0} \\ \mathcal{D} & \xrightarrow{\simeq} & \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{T}, \mathcal{D}) \end{array}$$

in which the horizontal maps are equivalences of $\mathcal{T}$-∞-categories. Therefore, for all $t \in \mathcal{T}$, we have an equivalence $\mathcal{D}^{(\sigma,\mathcal{T})/} \times_{\mathcal{D}} \mathcal{D}_t \simeq \mathcal{D}_t^{\sigma(t)/}$, and (1) follows by checking fiberwise.

For (2), suppose f is a $\mathcal{T}$-left fibration and σ is a $\mathcal{T}$-initial object of $\mathcal{D}$. Using (1), let $\tau : \mathcal{D} \longrightarrow \mathcal{D}^{(\sigma,\mathcal{T})/}$ be a choice of section. We then claim that the composite map

$$\chi : \mathcal{D} \xrightarrow{\tau} \mathcal{D}^{(\sigma,\mathcal{T})/} \xrightarrow{f} \mathcal{C}^{(f\sigma,\mathcal{T})/}$$

is an equivalence. Since χ is a $\mathcal{T}$-functor between $\mathcal{T}$-left fibrations over $\mathcal{C}$, it suffices to check that χ_t is an equivalence of left fibrations over $\mathcal{C}_t$ for all $t \in \mathcal{T}$. But χ_t is a functor of corepresentable left fibrations that preserves the initial object, and is thus an equivalence.

For (3), recall that $\underline{\mathrm{Map}}_{\mathcal{C}}(-,-)$ was defined as the straightening of the $\mathcal{T}$-left fibration $\mathrm{Tw}_{\mathcal{T}}(\mathcal{C}) \longrightarrow \mathcal{C}^{\mathrm{vop}} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{C}$ given by the $\mathcal{T}$-fiberwise twisted arrow category (cf. the discussion right after [Sha21, Thm. 11.5]). By (2), it then suffices to show that the pullback $\mathcal{D} = \mathcal{C} \times_{(\mathcal{C}^{\mathrm{vop}} \times_{\mathcal{T}^{\mathrm{op}}} C)} \mathrm{Tw}_{\mathcal{T}}(\mathcal{C})$ has a $\mathcal{T}$-initial object that projects to σ. But this again reduces to the fiberwise assertion about $\mathcal{C}_t \times_{(\mathcal{C}_t^{\mathrm{op}} \times \mathcal{C}_t)} \mathrm{Tw}(\mathcal{C}_t) \simeq (\mathcal{C}_t)^{\sigma(x)/}$; note that the assumption that σ is a *cocartesian* section ensures that the collection of fiberwise initial objects in $\mathcal{D}$ is stable under cocartesian pushforward, so it indeed promotes to a $\mathcal{T}$-initial object.

For (4), since $j_{\mathcal{T}}$ is fiberwise fully faithful and the formation of cocartesian sections computes the limit of the corresponding functor into **Cat**, it follows that $\widehat{j_{\mathcal{T}}}$ is fully faithful. The assertion now follows from (3).

For (5), we may check the assertion fiberwise, so suppose that $\mathcal{T}$ has a final object $*$. Then we need to show that for any $x \in \mathcal{C}_*$, $\operatorname{colim}^{\mathcal{T}} j_{\mathcal{T}}(x) \simeq 1 \in \mathbf{Spc}_{\mathcal{T}}$. But note that for all $t \in \mathcal{T}$, if we let $\alpha_t : t \longrightarrow *$ denote the unique morphism then $j_{\mathcal{T}}(x)|_{\mathcal{C}_t^{\mathrm{op}}} \simeq \operatorname{Map}_{\mathcal{C}_t}(-, \alpha_t^* x)$, hence in view of [Sha21, Prop. 5.5] the assertion follows from its non-parametrized analogue $\operatorname{colim}_{\mathcal{C}_t^{\mathrm{op}}} j(\alpha_t^* x) \simeq 1$. □

8. Finite, filtered, and sifted diagrams

In this section, we develop the theory of $\mathcal{T}$-κ-small, $\mathcal{T}$-filtered, and $\mathcal{T}$-sifted $\mathcal{T}$-∞-categories (Definition 8.2, Definition 8.8, and Definition 8.14). To prepare for our discussion, we begin with the following proposition, which recovers and extends the homotopy colimit decomposition result of [Lur09, Cor. 4.2.3.10]. Its statement involves the "lower $\mathcal{T}$-slice" construction of [Sha21, Def. 4.17].

8.1. **Theorem.** *Let $\mathcal{C}$ be a $\mathcal{T}$-∞-category.*

(1) The assignments $[K \xrightarrow{p} {}_\natural\mathcal{C}] \mapsto [{}_\natural\mathcal{C}_{(p,\mathcal{T})/} \longrightarrow \mathcal{C}]$ and $[L \xrightarrow{q} {}_\natural\mathcal{C}] \mapsto [{}_\natural\mathcal{C}_{/(p,\mathcal{T})} \longrightarrow {}_\natural\mathcal{C}]$ of marked simplicial sets assemble to a Quillen adjunction

$$\mathcal{C}_{(-,\mathcal{T})/} : s\mathbf{Set}^+_{/{}_\natural\mathcal{C}} \rightleftarrows (s\mathbf{Set}^+_{/{}_\natural\mathcal{C}})^{\mathrm{op}} : \mathcal{C}_{/(-,\mathcal{T})}$$

with respect to the slice model structure (and its opposite) induced from the cocartesian model structure on $s\mathbf{Set}^+_{/\mathcal{T}^{\mathrm{op}}}$. Consequently, we obtain an adjunction of ∞-categories

$$\mathcal{C}_{(-,\mathcal{T})/} : (\mathbf{Cat}_{\mathcal{T}})_{/\mathcal{C}} \rightleftarrows (\mathbf{Cat}_{\mathcal{T}})^{\mathrm{op}}_{/\mathcal{C}} : \mathcal{C}_{/(-,\mathcal{T})}.$$

(2) Let $p_\bullet : \mathcal{I} \longrightarrow (\mathbf{Cat}_{\mathcal{T}})_{/\mathcal{C}}$ be a functor with colimit $p : \mathcal{K} \longrightarrow \mathcal{C}$ and suppose that for every $i \in \mathcal{I}$, the $\mathcal{T}$-functor $p_i : \mathcal{K}_i \longrightarrow \mathcal{C}$ admits a $\mathcal{T}$-colimit σ_i. Then the σ_i assemble to a $\mathcal{T}$-functor $\sigma_\bullet : \mathcal{I} \times \mathcal{T}^{\mathrm{op}} \longrightarrow \mathcal{C}$ such that if $\sigma_\bullet$ admits a $\mathcal{T}$-colimit σ, then p admits a $\mathcal{T}$-colimit given by σ.

Proof. (1): Let us suppress the markings on $\mathcal{C}$ and its relatives for clarity. The two displayed functors participate in an adjunction in view of the definitional isomorphisms of hom-sets

$$\operatorname{Hom}_{/\mathcal{C}}(L, \mathcal{C}_{(p,\mathcal{T})/}) \cong \operatorname{Hom}_{K \sqcup L//\mathcal{T}^{\mathrm{op}}}(K \star_{\mathcal{T}^{\mathrm{op}}} (L \times_{\mathcal{T}^{\mathrm{op}}} \operatorname{Ar}(\mathcal{T}^{\mathrm{op}})^\sharp), C) \cong \operatorname{Hom}_{/\mathcal{C}}(K, \mathcal{C}_{/(q,\mathcal{T})}).$$

The left adjoint preserves cofibrations and weak equivalences by [Sha21, Prop. 4.18], [Sha21, Prop. 4.19], and the discussion immediately proceeding it, so the adjunction is Quillen. Finally, even though this adjunction is not generally simplicial, we may descend to an adjunction on the underlying ∞-categories by [Lur17, Cor. 1.3.4.26].

(2): Let $\overline{p_\bullet} : \mathcal{I}^\triangleright \longrightarrow (\mathbf{Cat}_{\mathcal{T}})_{/\mathcal{C}}$ be a colimit diagram extending $p_\bullet$ and let $\overline{\varphi} : (\mathcal{I}^{\mathrm{op}})^\triangleleft \longrightarrow (\mathbf{Cat}_{\mathcal{T}})_{/\mathcal{C}}$ be the opposite of the postcomposition of $\overline{p_\bullet}$ with $\mathcal{C}_{(-,\mathcal{T})/}$. By (1), $\overline{\varphi}$ is a limit diagram. We wish to show that the value $\mathcal{C}_{(p,\mathcal{T})/} \longrightarrow \mathcal{C}$ on its cone point is a $\mathcal{T}$-corepresentable $\mathcal{T}$-left fibration with $\mathcal{T}$-initial object as indicated.

By assumption, φ factors through the subcategory of $\mathcal{T}$-corepresentable $\mathcal{T}$-left fibrations over $\mathcal{C}$, hence by Lemma 7.8(4) applied to $\mathcal{C}^{\mathrm{vop}}$ and using that $(-)^{\mathrm{op}}$ preserves limits, we may factor φ^{op} as

$$\psi : \mathcal{I} \longrightarrow \operatorname{Fun}_{\mathcal{T}}(\mathcal{T}^{\mathrm{op}}, \mathcal{C}^{\mathrm{vop}})^{\mathrm{op}} \simeq \operatorname{Fun}_{\mathcal{T}}(\mathcal{T}^{\mathrm{op}}, \mathcal{C}).$$

Let $\sigma_\bullet : \mathcal{I} \times \mathcal{T}^{\mathrm{op}} \longrightarrow \mathcal{C}$ be the adjoint $\mathcal{T}$-functor and suppose $\sigma_\bullet$ extends to a $\mathcal{T}$-colimit diagram

$$\overline{\sigma_\bullet} : (\mathcal{I} \times \mathcal{T}^{\mathrm{op}}) \star_{\mathcal{T}^{\mathrm{op}}} \mathcal{T}^{\mathrm{op}} \simeq \mathcal{I}^\triangleright \times \mathcal{T}^{\mathrm{op}} \longrightarrow \mathcal{C}$$

(necessarily then adjoint to a colimit diagram $\overline{\psi} : \mathcal{I}^\triangleright \longrightarrow \operatorname{Fun}_{\mathcal{T}}(\mathcal{T}^{\mathrm{op}}, \mathcal{C})$ extending ψ). Since the $\mathcal{T}$-Yoneda embedding $j_{\mathcal{T}}$ strongly preserves $\mathcal{T}$-limits [Sha21, Cor. 11.10], we obtain a $\mathcal{T}$-limit diagram $j_{\mathcal{T}} \circ \overline{\sigma_\bullet}^{\mathrm{vop}}$ and thus a limit diagram

$$\widehat{j_{\mathcal{T}}} \circ \overline{\psi}^{\mathrm{op}} : (\mathcal{I}^{\mathrm{op}})^\triangleleft \longrightarrow \operatorname{Fun}_{\mathcal{T}}(\mathcal{T}^{\mathrm{op}}, \mathcal{C}^{\mathrm{vop}}) \longrightarrow \mathbf{P}_{\mathcal{T}}(\mathcal{C}^{\mathrm{vop}}) \simeq \mathbf{LFib}(\mathcal{C}).$$

Since $\mathbf{LFib}(\mathcal{C})$ is a subcategory of $(\mathbf{Cat}_{\mathcal{T}})_{/\mathcal{C}}$ stable under limits and $\overline{\varphi}$ factors through this subcategory, we deduce that $\overline{\varphi} \simeq \widehat{j_{\mathcal{T}}} \circ \overline{\psi}^{\mathrm{op}}$ as limit diagrams extending φ, which proves the claim. □

8.2. **Definition.** Let $\Delta_{\mathcal{T}} \subset \mathbf{Cat}_{\mathcal{T}} \simeq \operatorname{Fun}(\mathcal{T}^{\mathrm{op}}, \mathbf{Cat})$ be the full subcategory spanned by the objects $\{\Delta^n \times \operatorname{Map}_{\mathcal{T}}(-, t) : t \in \mathcal{T}, n \geq 0\}$. Then for every regular cardinal κ, define the full subcategory $\mathbf{Cat}_{\mathcal{T}}^{\kappa\text{-small}} \subset \mathbf{Cat}_{\mathcal{T}}$ of *$\mathcal{T}$-κ-small $\mathcal{T}$-∞-categories* to be the smallest full subcategory that contains $\Delta_{\mathcal{T}}$ and is closed under all colimits indexed by κ-small simplicial sets.

If $\kappa = \omega$, then we will also use the terminology $\mathcal{T}$-*finite* in place of $\mathcal{T}$-ω-small.

8.3. **Remark.** Let $i : \Delta \subset \mathbf{Cat}$ be the usual inclusion of the simplex category, which extends to the adjunction $[L\colon \mathbf{P}(\Delta) \rightleftarrows \mathbf{Cat} : R]$ whose fully faithful right adjoint exhibits $\mathbf{Cat}$ as the full subcategory of complete Segal spaces in $\mathbf{P}(\Delta)$. Then applying $\mathrm{Fun}(\mathcal{T}^{\mathrm{op}}, -)$ to $L \dashv R$ yields an adjunction $[L_{\mathcal{T}}\colon \mathbf{P}(\Delta \times \mathcal{T}) \rightleftarrows \mathbf{Cat}_{\mathcal{T}} : R_{\mathcal{T}}]$, where $L_{\mathcal{T}}$ is the unique functor extending $i_{\mathcal{T}} : \Delta \times \mathcal{T} \longrightarrow \mathbf{Cat}_{\mathcal{T}}, ([n], t) \mapsto \Delta^n \times \mathrm{Map}_{\mathcal{T}}(-, t)$ and $R_{\mathcal{T}}$ is fully faithful. In particular, $i_{\mathcal{T}}$ is fully faithful with essential image $\Delta_{\mathcal{T}}$. Furthermore, using that $\mathrm{id}_{\mathbf{P}(\Delta \times \mathcal{T})}$ is the left Kan extension of the Yoneda embedding along itself, we deduce that $\mathrm{id}_{\mathbf{Cat}_{\mathcal{T}}}$ is the left Kan extension of $i_{\mathcal{T}}$ along itself; indeed, for any $\mathcal{T}$-∞-category $\mathcal{C}$, applying the colimit-preserving functor $L_{\mathcal{T}}$ to the equivalence

$$R_{\mathcal{T}}(\mathcal{C}) \simeq \mathrm{colim}[(\Delta \times \mathcal{T}) \times_{\mathbf{P}(\Delta \times \mathcal{T})} \mathbf{P}(\Delta \times \mathcal{T})^{/R_{\mathcal{T}}(\mathcal{C})} \longrightarrow \mathbf{P}(\Delta \times \mathcal{T})]$$

and using that $(\Delta \times \mathcal{T}) \times_{\mathbf{P}(\Delta \times \mathcal{T})} \mathbf{P}(\Delta \times \mathcal{T})^{/R_{\mathcal{T}}(\mathcal{C})} \simeq (\Delta \times \mathcal{T}) \times_{\mathbf{Cat}_{\mathcal{T}}} (\mathbf{Cat}_{\mathcal{T}})^{/\mathcal{C}}$ proves the claim.

As a corollary, if κ_0 is the strongly inaccessible cardinal that fixes our definition of small simplicial set, then $\mathbf{Cat}_{\mathcal{T}}^{\kappa_0\text{-small}} = \mathbf{Cat}_{\mathcal{T}}$. Our definition of small $\mathcal{T}$-∞-category is thus unambiguous.

8.4. **Remark.** In Definition 8.2, if $\mathcal{T} = \Delta^0$, then the notion of a $\mathcal{T}$-κ-small $\mathcal{T}$-∞-category $\mathcal{C}$ coincides with that of an *essentially* κ-small ∞-category [Lur09, Def. 5.4.1.3]: that is, there exists a κ-small simplicial set K and a categorical equivalence $K \longrightarrow \mathcal{C}$. To see this, note that if $\mathcal{C}$ is essentially κ-small then by [Lur09, Var. 4.2.3.15] if $\kappa > \omega$ or [Lur09, Var. 4.2.3.16] if $\kappa = \omega$, there exists a κ-small simplicial set L and a map $\phi : L \longrightarrow \Delta$ such that $\mathcal{C} \simeq \mathrm{colim}_L \phi$. Conversely, the full subcategory of essentially κ-small ∞-categories is closed under κ-small colimits by a direct argument if $\kappa = \omega$ and by the identification with κ-compact objects in $\mathbf{Cat}$ if $\kappa > \omega$ [Lur09, Prop. 5.4.1.2].

8.5. **Remark.** We may describe the ∞-category $\mathbf{Cat}_{\mathcal{T}}^{\kappa\text{-small}}$ more explicitly in the following manner. Define an increasing union of full subcategories $(\mathbf{Cat}_{\mathcal{T}}^{\kappa\text{-small}})_\alpha \subset \mathbf{Cat}_{\mathcal{T}}^{\kappa\text{-small}}$ for all ordinals $\alpha \leq \kappa$ inductively as follows:

(0) $(\mathbf{Cat}_{\mathcal{T}}^{\kappa\text{-small}})_0 = \Delta_{\mathcal{T}}$.
(1) For every successor ordinal $\beta = \alpha + 1$, let $(\mathbf{Cat}_{\mathcal{T}}^{\kappa\text{-small}})_\beta$ consist of all colimits of diagrams

$$K \longrightarrow (\mathbf{Cat}_{\mathcal{T}}^{\kappa\text{-small}})_\alpha$$

indexed by κ-small simplicial sets K.
(2) For every limit ordinal $\lambda \leq \kappa$, let $(\mathbf{Cat}_{\mathcal{T}}^{\kappa\text{-small}})_\lambda = \bigcup_{\alpha < \lambda} (\mathbf{Cat}_{\mathcal{T}}^{\kappa\text{-small}})_\alpha$.

Then since the ordinal κ is itself κ-filtered, we conclude that $\mathbf{Cat}_{\mathcal{T}}^{\kappa\text{-small}} = (\mathbf{Cat}_{\mathcal{T}}^{\kappa\text{-small}})_\kappa$.

We now apply Theorem 8.1 to prove a κ-$\mathcal{T}$-cocompleteness result that generalizes [Sha21, Cor. 12.15], with a different method of proof.

8.6. **Theorem.** *Let $\mathcal{C}$ be a $\mathcal{T}$-∞-category and κ a regular cardinal. Then $\mathcal{C}$ strongly admits all $\mathcal{T}$-κ-small $\mathcal{T}$-colimits if and only if*

(1) For every $t \in \mathcal{T}$, $\underline{\mathcal{C}_t}$ admits $\mathcal{T}^{/t}$-colimits indexed by corepresentable left fibrations.
(2) For every $t \in \mathcal{T}$, $\mathcal{C}_t$ admits κ-small colimits, and for every $\alpha : s \longrightarrow t$, the restriction functor $\alpha^* : \mathcal{C}_t \longrightarrow \mathcal{C}_s$ preserves κ-small colimits.

Furthermore, if $\mathcal{C}$ and $\mathcal{D}$ are $\mathcal{T}$-∞-categories that strongly admit $\mathcal{T}$-κ-small $\mathcal{T}$-colimits and $F : \mathcal{C} \longrightarrow \mathcal{D}$ is a $\mathcal{T}$-functor, then F strongly preserves all $\mathcal{T}$-κ-small $\mathcal{T}$-colimits if and only if

a. For every $\alpha : s \longrightarrow t$, the mate $\alpha_! F_s \Rightarrow F_t \alpha_!$ is an equivalence.
b. For every $t \in \mathcal{T}$, F_t preserves all κ-small colimits.

Proof. For the 'only if' direction, suppose that $\mathcal{C}$ strongly admits $\mathcal{T}$-colimits. Then (1) holds since $\Delta_{\mathcal{T}^{/t}} \subset \mathbf{Cat}_{\mathcal{T}^{/t}}^{\kappa\text{-small}}$ by definition, and (2) holds since if $\mathcal{K}$ is an essentially κ-small ∞-category, then as noted in Remark 8.4 there exists a κ-small simplicial set L and a functor $\phi : L \longrightarrow \Delta \times \{\mathrm{id}_t\} \subset \Delta \times \mathcal{T}^{/t} \xrightarrow{\simeq} \Delta_{\mathcal{T}^{/t}}$ such that $\mathcal{K} \times (\mathcal{T}^{/t})^{\mathrm{op}} \simeq \mathrm{colim}_L \phi$ in $\mathbf{Cat}_{\mathcal{T}}$, hence $\mathcal{K} \times (\mathcal{T}^{/t})^{\mathrm{op}}$ is a $\mathcal{T}$-κ-small $\mathcal{T}$-∞-category.

Conversely, suppose $\mathcal{C}$ satisfies (1) and (2). Let $\mathcal{K}_t$ denote the full subcategory of $\mathbf{Cat}_{\mathcal{T}^{/t}}$ consisting of all $\mathcal{T}^{/t}$-∞-categories $\mathcal{K}$ such that all $\mathcal{K}$-indexed $\mathcal{T}^{/t}$-diagrams in $\underline{\mathcal{C}_t}$ admit $\mathcal{T}^{/t}$-colimits. We wish to show that $\mathcal{K}_t$ contains $\mathbf{Cat}_{\mathcal{T}^{/t}}^{\kappa\text{-small}}$. To ease notation, let us replace $\mathcal{T}^{/t}$ by $\mathcal{T}$ and suppose that $\mathcal{T}$ has a final object $*$. By our first assumption, $\mathcal{K}_*$ contains Δ_T. It thus suffices to show that $\mathcal{K}_*$ is closed under κ-small colimits in $\mathbf{Cat}_T$. So suppose we have a diagram $f : I \longrightarrow \mathcal{K}_*$ with I κ-small such that f has colimit $\mathcal{K}$ in $\mathbf{Cat}_{\mathcal{T}}$, and let $p : \mathcal{K} \longrightarrow \mathcal{C}$ be a $\mathcal{T}$-functor. Then since colimits in $(\mathbf{Cat}_{\mathcal{T}})_{/\mathcal{C}}$ are created by the forgetful functor to $\mathbf{Cat}_{\mathcal{T}}$, we obtain a colimit diagram $p_\bullet : I^{\triangleright} \longrightarrow (\mathbf{Cat}_{\mathcal{T}})_{/\mathcal{C}}$ such that for each $i \in I$, the $\mathcal{T}$-functor p_i admits a $\mathcal{T}$-colimit $x_i \in \mathcal{C}_*$. By our second assumption combined with [Sha21, Cor. 5.9] and Theorem 8.1(2), we deduce that p admits a $\mathcal{T}$-colimit, which proves the claim. Repeating the same type of argument establishes the assertion about the $\mathcal{T}$-functor F. □

8.7. **Remark.** If we suppose that $\mathcal{T}$ is orbital in Theorem 8.6, then by [Sha21, Prop. 5.12] we may replace (1) with the assumption that for all $\alpha : s \longrightarrow t$, α^* admits a left adjoint $\alpha_!$, and for all pullback squares in $\mathbf{F}_{\mathcal{T}}$

$$\begin{array}{ccc} U' & \xrightarrow{\beta'} & U \\ \downarrow{\scriptstyle \alpha'} & & \downarrow{\scriptstyle \alpha} \\ V' & \xrightarrow{\beta} & V, \end{array}$$

the mate $\alpha'_! \beta'^* \Rightarrow \beta^* \alpha_!$ is an equivalence.

8.8. **Definition.** Let $\mathcal{J}$ be a $\mathcal{T}$-∞-category and let κ be a regular cardinal. Then $\mathcal{J}$ is $\mathcal{T}$-*κ-filtered* if for all $t \in \mathcal{T}$ and $\mathcal{T}^{/t}$-κ-small $\mathcal{K}$, every $\mathcal{T}^{/t}$-functor $p : \mathcal{K} \longrightarrow \mathcal{J}_{\underline{t}}$ admits an extension to a $\mathcal{T}^{/t}$-functor $\overline{p} : \mathcal{K}^{\underline{\triangleright}} \longrightarrow \mathcal{J}_{\underline{t}}$.

8.9. **Lemma.** *Suppose that $\mathcal{T}$ is orbital and has a final object $*$. Let κ be a regular cardinal and suppose that $\mathcal{K}$ and $\mathcal{L}$ are $\mathcal{T}$-κ-small $\mathcal{T}$-∞-categories. Then $\mathcal{K} \star_{\mathcal{T}^{\mathrm{op}}} \mathcal{L}$ is $\mathcal{T}$-κ-small.*

Proof. Let $(\mathbf{Cat}_{\mathcal{T}}^{\kappa\text{-small}})_\alpha$ be as in Remark 8.5. First observe that if $\mathcal{K} = \Delta^n \times (\mathcal{T}^{/t})^{\mathrm{op}}$ and $\mathcal{L} = \Delta^m \times (\mathcal{T}^{/s})^{\mathrm{op}}$, then $\mathcal{K} \times \mathcal{L} \in (\mathbf{Cat}_{\mathcal{T}}^{\omega\text{-small}})_1$ using that $\mathcal{T}$ is orbital. Because

$$\mathcal{K} \star_{\mathcal{T}^{\mathrm{op}}} \mathcal{L} \simeq (\mathcal{K} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{L}) \times \Delta^1 \coprod_{(\mathcal{K} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{L}) \times \partial\Delta^1} \mathcal{K} \sqcup \mathcal{L} \,,$$

we deduce that the $\mathcal{T}$-join restricts to a functor $\Delta_{\mathcal{T}} \times \Delta_{\mathcal{T}} \longrightarrow (\mathbf{Cat}_{\mathcal{T}}^{\omega\text{-small}})_1 \subset (\mathbf{Cat}_{\mathcal{T}}^{\kappa\text{-small}})_1$. We then formulate the following inductive hypothesis:

(1) If $\beta = \alpha + 1 < \kappa$ is a successor ordinal, then for all $\mathcal{K}, \mathcal{L} \in (\mathbf{Cat}_{\mathcal{T}}^{\kappa\text{-small}})_\alpha$, $\mathcal{K} \star_{\mathcal{T}^{\mathrm{op}}} \mathcal{L} \in (\mathbf{Cat}_{\mathcal{T}}^{\kappa\text{-small}})_\beta$.
(2) If $\lambda \leq \kappa$ is a limit ordinal, then for all $\mathcal{K}, \mathcal{L} \in (\mathbf{Cat}_{\mathcal{T}}^{\kappa\text{-small}})_\lambda$, $\mathcal{K} \star_{\mathcal{T}^{\mathrm{op}}} \mathcal{L} \in (\mathbf{Cat}_{\mathcal{T}}^{\kappa\text{-small}})_\lambda$.

Because the $\mathcal{T}$-join preserves colimits separately in each variable (as may be checked fiberwise) and κ is a regular cardinal, we may proceed by induction to confirm the inductive hypothesis for all $\lambda \leq \kappa$; this proves the claim since $\mathbf{Cat}_{\mathcal{T}}^{\kappa\text{-small}} = (\mathbf{Cat}_{\mathcal{T}}^{\kappa\text{-small}})_\kappa$. □

8.10. **Lemma.** *Suppose that $\mathcal{T}$ is orbital and $\mathcal{J}$ is $\mathcal{T}$-κ-filtered. Then for any $\mathcal{T}^{/t}$-κ-small $\mathcal{K}$ and $\mathcal{T}^{/t}$-functor $p : \mathcal{K} \longrightarrow \mathcal{J}_{\underline{t}}$, $(\mathcal{J}_{\underline{t}})^{(p,\mathcal{T}^{/t})/}$ is $\mathcal{T}^{/t}$-κ-filtered.*

Proof. Replace $\mathcal{T}^{/t}$ by $\mathcal{T}$ and suppose $\mathcal{K}$ is $\mathcal{T}$-κ-small and $p : \mathcal{K} \longrightarrow \mathcal{J}$ is a $\mathcal{T}$-functor. To check that $\mathcal{J}^{(p,\mathcal{T})/}$ is $\mathcal{T}$-filtered, after replacing $\mathcal{T}^{/t}$ by $\mathcal{T}$ once more it suffices to show that for any $\mathcal{T}$-functor $\phi : \mathcal{L} \longrightarrow \mathcal{J}^{(p,\mathcal{T})/}$ with $\mathcal{T}$-κ-small $\mathcal{L}$, ϕ extends over $\mathcal{L}^{\underline{\triangleright}}$. Using that $\mathcal{J}^{(p,\mathcal{T})/} \simeq \mathcal{J}_{(p,\mathcal{T})/}$, by adjunction it suffices to extend the $\mathcal{T}$-functor $\psi : \mathcal{K} \star_{\mathcal{T}^{\mathrm{op}}} \mathcal{L} \longrightarrow \mathcal{J}$ (under $p \sqcup q$) over $(\mathcal{K} \star_{\mathcal{T}^{\mathrm{op}}} \mathcal{L})^{\underline{\triangleright}}$. By our assumption that $\mathcal{J}$ is $\mathcal{T}$-filtered, this is possible since $\mathcal{K} \star_{\mathcal{T}^{\mathrm{op}}} \mathcal{L}$ is $\mathcal{T}$-κ-small by Lemma 8.9. □

8.11. **Theorem.** *Suppose that $\mathcal{T}$ is orbital. Let $\mathcal{J}$ be a $\mathcal{T}$-∞-category and let κ be a regular cardinal. The following conditions are equivalent:*

(1) $\mathcal{J}$ is $\mathcal{T}$-κ-filtered.
(2) For all $t \in \mathcal{T}$, $\mathcal{J}_t$ is κ-filtered, and $\mathcal{J}$ is cofinal-constant (Definition 9.5).
(3) The $\mathcal{T}$-colimit $\mathcal{T}$-functor $\underline{\operatorname{colim}}^{\mathcal{T}}_{\mathcal{J}} : \underline{\operatorname{Fun}}_{\mathcal{T}}(\mathcal{J}, \underline{\mathbf{Spc}}_{\mathcal{T}}) \longrightarrow \underline{\mathbf{Spc}}_{\mathcal{T}}$ strongly preserves $\mathcal{T}$-κ-small $\mathcal{T}$-limits.

Proof. First suppose (1). Then for any essentially κ-small ∞-category $\mathcal{K}$ and $t \in \mathcal{T}$, our assumption ensures that every $\mathcal{T}^{/t}$-functor $\mathcal{K} \times (\mathcal{T}^{/t})^{\mathrm{op}} \longrightarrow \mathcal{J}_{\underline{t}}$ extends over $\mathcal{K}^{\triangleright} \times (\mathcal{T}^{/t})^{\mathrm{op}}$, which shows that $\mathcal{J}_t$ is κ-filtered. Now suppose $\alpha : s \longrightarrow t$ is a morphism in $\mathcal{T}$. We want to show that $\alpha^* : \mathcal{J}_t \longrightarrow \mathcal{J}_s$ is cofinal. Let $x \in \mathcal{J}_s$ and $\sigma : (\mathcal{T}^{/s})^{\mathrm{op}} \longrightarrow \mathcal{J}_{\underline{t}}$ be the unique $\mathcal{T}^{/t}$-functor that selects x, and note that by Lemma 7.1

$$\mathcal{J}_t \times_{\mathcal{J}_s} (\mathcal{J}_s)^{x/} \simeq ((\mathcal{J}_{\underline{t}})^{(\sigma,\mathcal{T}^{/t})/})_t.$$

By Lemma 8.10, $(\mathcal{J}_{\underline{t}})^{(\sigma,\mathcal{T}^{/t})/}$ is $\mathcal{T}^{/t}$-κ-filtered, so $((\mathcal{J}_{\underline{t}})^{(\sigma,\mathcal{T}^{/t})/})_t$ is κ-filtered by what was previously shown, and hence weakly contractible.[23] The claim now follows by Joyal's cofinality theorem. We conclude that $\mathcal{J}$ is cofinal-constant, so $\mathcal{J}$ satisfies (2).

Next suppose (2). To show (3), by the dual of Theorem 8.6 it suffices to show that $\mathrm{colim}^{\mathcal{T}}_{\mathcal{J}}$ preserves κ-small limits fiberwise and intertwines with the 'coinduction' right adjoints. By [Sha21, Prop. 5.5], under the equivalence $\mathrm{Fun}_{\mathcal{T}^{/t}}(\mathcal{J}_{\underline{t}}, \underline{\mathbf{Spc}}_{\mathcal{T}^{/t}}) \simeq \mathrm{Fun}(\mathcal{J}_{\underline{t}}, \mathbf{Spc})$, the functor $\mathrm{colim}^{\mathcal{T}^{/t}}_{\mathcal{J}_{\underline{t}}}$ identifies with left Kan extension along the structure map $\mathcal{J}_{\underline{t}} \longrightarrow (\mathcal{T}^{/t})^{\mathrm{op}}$. In view of our assumption that the fibers of $\mathcal{J}$ are κ-filtered, by [Lur09, Prop. 5.3.3.3] and [Lur09, Prop. 4.3.3.10] we conclude that $\mathrm{colim}^{\mathcal{T}^{/t}}_{\mathcal{J}_{\underline{t}}}$ preserves κ-small limits. Next, let $\alpha : s \longrightarrow t$ be a morphism in $\mathcal{T}$ and consider the resulting pullback square

$$\begin{array}{ccc} \mathcal{J}_{\underline{s}} & \xrightarrow{\phi} & \mathcal{J}_{\underline{t}} \\ \downarrow \pi & & \downarrow \pi \\ (\mathcal{T}^{/s})^{\mathrm{op}} & \xrightarrow{\phi} & (\mathcal{T}^{/t})^{\mathrm{op}} \end{array} \quad \text{yielding} \quad \begin{array}{ccc} \mathrm{Fun}(\mathcal{J}_{\underline{t}}, \mathbf{Spc}) & \xrightarrow{\pi_!} & \mathrm{Fun}((\mathcal{T}^{/t})^{\mathrm{op}}, \mathbf{Spc}) \\ \phi_* \uparrow & \Searrow & \phi_* \uparrow \\ \mathrm{Fun}(\mathcal{J}_{\underline{s}}, \mathbf{Spc}) & \xrightarrow{\pi_!} & \mathrm{Fun}((\mathcal{T}^{/s})^{\mathrm{op}}, \mathbf{Spc}). \end{array}$$

We need to show that the mate $\chi : \pi_! \phi_* \Rightarrow \phi_* \pi_!$ is an equivalence. To ease notation, let us replace $\mathcal{T}^{/t}$ by $\mathcal{T}$ and t by $*$. Let $p : \mathcal{J}_* \times \mathcal{T}^{\mathrm{op}} \longrightarrow \mathcal{J}$ be the unique $\mathcal{T}$-functor extending the inclusion $\mathcal{J}_* \subset \mathcal{J}$ and note that our assumption that p is $\mathcal{T}$-cofinal yields a factorization of $\underline{\mathrm{colim}}^{\mathcal{T}}_{\mathcal{J}}$ as

$$\underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{J}, \underline{\mathbf{Spc}}_{\mathcal{T}}) \xrightarrow{p^*} \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{J}_* \times \mathcal{T}^{\mathrm{op}}, \underline{\mathbf{Spc}}_{\mathcal{T}}) \xrightarrow{\underline{\mathrm{colim}}^{\mathcal{T}}_{\mathcal{J}_* \times \mathcal{T}^{\mathrm{op}}}} \underline{\mathbf{Spc}}_{\mathcal{T}}.$$

Since the $\mathcal{T}$-functor p^* admits a $\mathcal{T}$-left adjoint given by $\mathcal{T}$-left Kan extension, p^* commutes with all $\mathcal{T}$-limits [Sha21, Cor. 8.9]. We may thus replace $\mathcal{J}$ by the constant diagram $\mathcal{J}_* \times \mathcal{T}^{\mathrm{op}}$ in the proof.

Now let $F : \mathcal{J}_* \times (\mathcal{T}^{/s})^{\mathrm{op}} \longrightarrow \mathbf{Spc}$ be a functor and $u \in \mathcal{T}$; we will show that $\chi_F(u)$ is an equivalence. For every $\gamma : v \longrightarrow s$, let $F_\gamma = F|_{\mathcal{J}_* \times \{\gamma\}}$. Invoking our assumption that $\mathcal{T}$ is orbital, let $\{v_i \in \mathcal{T} : i \in I\}$ be a finite collection such that $\mathcal{T}^{/s} \times_{\mathcal{T}} \mathcal{T}^{/u} \simeq \coprod_{i \in I} \mathcal{T}^{/v_i}$ and let $\gamma_i : v_i \longrightarrow s$ be the structure maps. Then

$$(\phi_* \pi_! F)(u) \simeq \lim \left(\coprod_{i \in I} (\mathcal{T}^{\mathrm{op}})^{v_i/} \longrightarrow (\mathcal{T}^{\mathrm{op}})^{s/} \xrightarrow{\pi_! F} \mathbf{Spc} \right) \simeq \prod_{i \in I} (\pi_! F)(\gamma_i) \simeq \prod_{i \in I} \mathrm{colim}_{\mathcal{J}_*} F_{\gamma_i}$$

On the other hand, using that the upper ϕ is a map of cartesian fibrations over $\mathcal{J}_*$, we get that $\phi_* F$ is computed fiberwise over $\mathcal{J}_*$ by [Lur09, Prop. 4.3.3.10]. Thus for all $x \in \mathcal{J}_*$,

$$(\phi_* F)(x, u) \simeq \lim \left(\coprod_{i \in I} (\mathcal{T}^{\mathrm{op}})^{v_i/} \longrightarrow \{x\} \times (\mathcal{T}^{\mathrm{op}})^{s/} \xrightarrow{F} \mathbf{Spc} \right) \simeq \prod_{i \in I} F(x, \gamma_i),$$

and using that κ-filtered colimits commute with finite products in $\mathbf{Spc}$, we deduce that $\chi_F(u)$ is an equivalence.

Finally, suppose (3). To show (1), after the usual reduction it suffices to prove that if $\mathcal{T}$ admits a final object $*$ and $q : \mathcal{K} \longrightarrow \mathcal{J}$ is a $\mathcal{T}$-functor with $\mathcal{K}$ $\mathcal{T}$-κ-small, then $(\mathcal{C}^{(q,\mathcal{T})/})_*$ is nonempty. Let $\varphi = \lim^{\mathcal{T}}_{\mathcal{K}^{\mathrm{vop}}} (j_{\mathcal{T}} q^{\mathrm{vop}}) \in \mathbf{P}_{\mathcal{T}}(\mathcal{J}^{\mathrm{vop}}) \simeq \mathrm{Fun}(\mathcal{J}, \mathbf{Spc})$. Then

$$\mathrm{colim}^{\mathcal{T}}_{\mathcal{J}}(\varphi) \simeq \lim^{\mathcal{T}}_{\mathcal{K}^{\mathrm{vop}}} (\underline{\mathrm{colim}}^{\mathcal{T}}_{\mathcal{J}} j_{\mathcal{T}} q^{\mathrm{vop}}) \simeq \lim^{\mathcal{T}}_{\mathcal{K}^{\mathrm{vop}}} (1_{\mathcal{T}}) \simeq 1_{\mathcal{T}},$$

using that $\underline{\mathrm{colim}}^{\mathcal{T}} j_{\mathcal{T}}$ factors through the $\mathcal{T}$-final object $1_{\mathcal{T}}$ of $\underline{\mathbf{Spc}}_{\mathcal{T}}$ by Lemma 7.8(5) and any $\mathcal{T}$-limit of $\mathcal{T}$-final objects is again $\mathcal{T}$-final. By Proposition 7.5 applied to $p = q^{\mathrm{vop}}$ and Lemma 8.12, we deduce that $(\mathcal{C}^{(q,\mathcal{T})/})_*$ is weakly contractible, so in particular nonempty. □

8.12. **Lemma.** *Let $\pi : \mathcal{C} \longrightarrow \mathcal{T}^{\mathrm{op}}$ be a $\mathcal{T}$-∞-category, $p : \mathcal{D} \longrightarrow \mathcal{C}$ a $\mathcal{T}$-left fibration, and $F : \mathcal{C} \longrightarrow \underline{\mathbf{Spc}}_{\mathcal{T}}$ a $\mathcal{T}$-functor that classifies p. Let $|\mathcal{D}|_{\mathcal{T}}$ denote the $\mathcal{T}$-space obtained by inverting all morphisms in the fibers $\mathcal{D}_t$ for all $t \in \mathcal{T}$. Then $|\mathcal{D}|_{\mathcal{T}} \simeq \mathrm{colim}^{\mathcal{T}} F$.*

[23] In fact, we don't need to invoke Lemma 8.9 as in the proof of Lemma 8.10 because we are only interested in the extension property for constant $\mathcal{T}^{/t}$-diagrams; in particular, the assumption that $\mathcal{T}$ is orbital there is not necessary in this instance.

Proof. Recall again that under the equivalence $\mathrm{Fun}_{\mathcal{T}}(\mathcal{C}, \underline{\mathbf{Spc}}_{\mathcal{T}}) \simeq \mathrm{Fun}(\mathcal{C}, \mathbf{Spc})$ and the identification of $\mathcal{T}$-left fibrations with left fibrations, p is classified as a left fibration by $F^\dagger : \mathcal{C} \longrightarrow \mathbf{Spc}$ and $\mathrm{colim}^{\mathcal{T}} F \simeq \pi_! F^\dagger$. Denote the classifying space adjunction by $|-|: \mathbf{Cat} \rightleftarrows \mathbf{Spc} : \iota$. In view of the functoriality of the straightening equivalence [Lur09, Prop. 3.2.1.4], we have that the functor $\mathbf{LFib}(\mathcal{C}) \longrightarrow \mathbf{LFib}(\mathcal{T}^{\mathrm{op}})$ defined by $\mathcal{D} \mapsto |\mathcal{D}|_{\mathcal{T}}$ identifies with the composite

$$L : \mathrm{Fun}(\mathcal{C}, \mathbf{Spc}) \xrightarrow{\iota} \mathrm{Fun}(\mathcal{C}, \mathbf{Cat}) \xrightarrow{\pi_!} \mathrm{Fun}(\mathcal{T}^{\mathrm{op}}, \mathbf{Cat}) \xrightarrow{|-|} \mathrm{Fun}(\mathcal{T}^{\mathrm{op}}, \mathbf{Spc}).$$

Since $\pi^* \iota \simeq \iota \pi^*$ the right adjoint of L identifies with π^*, so L is canonically equivalent to $\pi_!$. □

8.13. **Theorem.** *Suppose that $\mathcal{T}$ is orbital. Let $\mathcal{J}$ be a $\mathcal{T}$-∞-category and κ a regular cardinal. Then $\mathcal{J}$ is $\mathcal{T}$-κ-filtered if and only if for all $t \in \mathcal{T}$ and $\mathcal{T}^{/t}$-κ-small $\mathcal{K}$, the diagonal $\mathcal{T}^{/t}$-functor*

$$\delta : \mathcal{J}_{\underline{t}} \longrightarrow \underline{\mathrm{Fun}}_{\mathcal{T}^{/t}}(\mathcal{K}, \mathcal{J}_{\underline{t}})$$

is $\mathcal{T}^{/t}$-cofinal.

Proof. In the proof, let us replace $\mathcal{T}^{/t}$ with $\mathcal{T}$ and suppose that $\mathcal{T}$ has a final object $*$. For the 'if' direction, after replacing $\mathcal{T}^{/t}$ by $\mathcal{T}$ once more it suffices to show that for any $\mathcal{T}$-κ-small $\mathcal{K}$ and $\mathcal{T}$-functor $p : \mathcal{K} \longrightarrow \mathcal{J}$, p extends over $\mathcal{K}^{\underline{\triangleright}}$, i.e., $(\mathcal{J}^{(p,\mathcal{T})/})_*$ is nonempty. But since $(\mathcal{J}^{(p,\mathcal{T})/})_* \simeq \mathcal{J}_* \times_{\mathrm{Fun}_{\mathcal{T}}(\mathcal{K},\mathcal{J})} \mathrm{Fun}_{\mathcal{T}}(\mathcal{K}, \mathcal{J})^{\{p\}/}$ by the dual of Lemma 7.1, this follows by our assumption that $\mathcal{J}_* \longrightarrow \mathrm{Fun}_{\mathcal{T}}(\mathcal{K}, \mathcal{J})$ is cofinal. Conversely, for the 'only if' direction suppose that $\mathcal{J}$ is $\mathcal{T}$-κ-filtered and let $\mathcal{K}$ be $\mathcal{T}$-κ-small. After replacing $\mathcal{T}^{/t}$ by $\mathcal{T}$, it suffices to show that δ_* is cofinal. For this, by Joyal's cofinality theorem and Lemma 7.1 again, it suffices to show that $(\mathcal{J}^{(p,\mathcal{T})/})_*$ is weakly contractible for all $p : \mathcal{K} \longrightarrow \mathcal{J}$. But this follows by Lemma 8.10 and the (1)⇒(2) implication of Theorem 8.11. □

To formulate the notion of a $\mathcal{T}$-sifted $\mathcal{T}$-∞-category, we adopt the viewpoint of the alternative characterization of Theorem 8.13, but over a more restrictive class of diagrams.

8.14. **Definition.** Let $\mathcal{J}$ be a $\mathcal{T}$-∞-category. Then $\mathcal{J}$ is $\mathcal{T}$-*sifted* if for all $t \in \mathcal{T}$ and finite $\mathcal{T}^{/t}$-sets U, the diagonal $\mathcal{T}^{/t}$-functor $\delta : \mathcal{J}_{\underline{t}} \longrightarrow \underline{\mathrm{Fun}}_{\mathcal{T}^{/t}}(\underline{U}, \mathcal{J}_{\underline{t}})$ is $\mathcal{T}^{/t}$-cofinal.

8.15. **Theorem.** *Suppose that $\mathcal{T}$ is orbital and let $\mathcal{J}$ be a $\mathcal{T}$-∞-category. The following conditions are equivalent:*

(1) $\mathcal{J}$ is $\mathcal{T}$-sifted.
(2) For all $t \in \mathcal{T}$, $\mathcal{J}_t$ is sifted, and $\mathcal{J}$ is cofinal-constant (Definition 9.5).
(3) The $\mathcal{T}$-colimit $\mathcal{T}$-functor $\underline{\mathrm{colim}}^{\mathcal{T}}_{\mathcal{J}} : \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{J}, \underline{\mathbf{Spc}}_{\mathcal{T}}) \longrightarrow \underline{\mathbf{Spc}}_{\mathcal{T}}$ preserves finite $\mathcal{T}$-products.

Proof. First suppose (1). Then for $t \in \mathcal{T}$ and $U = \mathrm{id}_t \sqcup \mathrm{id}_t$, the $\mathcal{T}^{/t}$-cofinality of $\delta : \mathcal{J}_{\underline{t}} \longrightarrow \underline{\mathrm{Fun}}_{\mathcal{T}}(\underline{U}, \mathcal{J}_{\underline{t}})$ ensures that $\mathcal{J}_t$ is sifted, whereas if we let $U = [\alpha : s \longrightarrow t]$, then because $\delta_{\mathrm{id}_t} \simeq \alpha^* : \mathcal{J}_t \longrightarrow \mathcal{J}_s$ we deduce that α^* is cofinal, hence $\mathcal{J}$ is cofinal-constant. This shows that $\mathcal{J}$ satisfies (2).

The implication (2)⇒(3) follows by the same proof as (2)⇒(3) in Theorem 8.11. Finally, suppose (3). By Joyal's cofinality theorem and Lemma 7.1, it suffices to show that for all $t \in \mathcal{T}$, finite $\mathcal{T}^{/t}$-set U, and $\mathcal{T}^{/t}$-functor $p : \underline{U} \longrightarrow \mathcal{J}_{\underline{t}}$, the ∞-category $((\mathcal{J}_{\underline{t}})^{(p,\mathcal{T}^{/t})/})_{\mathrm{id}_t}$ is weakly contractible. But this follows by the same proof as (3)⇒(1) in Theorem 8.11. □

We end this section by explaining a parametrized generalization of the following fact: if $F : \mathcal{C} \times \mathcal{C} \longrightarrow \mathcal{D}$ is a functor that commutes with colimits separately in each variable, then F preserves sifted colimits. To do this, we need to recall the appropriate parametrized notion of distributive functor, whose definition is due to Nardin. We first fix some local notation.

8.16. **Definition.** Let U be a finite $\mathcal{T}$-set. A $\underline{U}$-∞-*category* is a cocartesian fibration over $\underline{U}$.[24]

8.17. **Notation.** Let $f : U \longrightarrow V$ be a map of finite $\mathcal{T}$-sets. Then we have the adjunction

$$f^* : \mathbf{Cat}_{\underline{V}} \rightleftarrows \mathbf{Cat}_{\underline{U}} : f_*$$

where f^* is pullback along $\underline{U} \longrightarrow \underline{V}$. Note also that some authors also prefer to write f_* as $\prod_f$ to emphasize its interpretation as an indexed product.

[24]Perhaps confusingly, this is reversing our convention that a $\mathcal{T}$-∞-category is a cocartesian fibration over $\mathcal{T}^{\mathrm{op}}$. However, we don't want to write "$\underline{U}^{\mathrm{op}}$-$\infty$-category".

To understand the following definition, the reader should convince themselves that it reduces to "preserving colimits separately in each variable" when $\mathcal{T} = *$.

8.18. **Definition** ([Nar17, Def. 3.15])**.** Suppose that $\mathcal{T}$ is orbital, let $f : U \longrightarrow V$ be a map of finite $\mathcal{T}$-sets, let $\mathcal{C}$ be a $\underline{U}$-∞-category, and let $\mathcal{D}$ be a $\underline{V}$-∞-category. Let $F : f_* \mathcal{C} \longrightarrow \mathcal{D}$ be a $\underline{V}$-functor. Then we say that F is *$\underline{V}$-distributive* if for every pullback square

$$\begin{array}{ccc} U' & \xrightarrow{f'} & V' \\ \downarrow{\scriptstyle g'} & & \downarrow{\scriptstyle g} \\ U & \xrightarrow{f} & V \end{array}$$

of finite $\mathcal{T}$-sets and $\underline{U'}$-colimit diagram $\overline{p} : \mathcal{K}^{\underline{\triangleright}} \longrightarrow g'^* \mathcal{C}$, the $\underline{V'}$-functor

$$(f'_* \mathcal{K})^{\underline{\triangleright}} \xrightarrow{\text{can}} f'_*(\mathcal{K}^{\underline{\triangleright}}) \xrightarrow{f'_* \overline{p}} f'_* g'^* \mathcal{C} \simeq g^* f_* \mathcal{C} \xrightarrow{g^* F} g^* \mathcal{D}$$

is a $\underline{V'}$-colimit diagram.[25]

8.19. **Proposition.** *Suppose that $\mathcal{T}$ is orbital, let $f : U \longrightarrow V$ be a map of finite $\mathcal{T}$-sets, and let $\mathcal{C}$ resp. $\mathcal{D}$ be a $\underline{U}$ resp. $\underline{V}$-∞-category. Suppose that $F : f_* \mathcal{C} \longrightarrow \mathcal{D}$ is a $\underline{V}$-distributive $\underline{V}$-functor. Then F strongly preserves $\underline{V}$-sifted $\underline{V}$-colimits.*

Proof. Since the property of parametrized distributivity is stable under base-change, it suffices to show that F preserves $\underline{V}$-sifted $\underline{V}$-colimits. Without loss of generality, we may also suppose that V is an orbit. Let $\mathcal{K}$ be a $\underline{V}$-sifted $\underline{V}$-∞-category and suppose that $\overline{p} : \mathcal{K}^{\underline{\triangleright}} \longrightarrow f_* \mathcal{C}$ is a $\underline{V}$-colimit diagram. Then because the counit map $f^* f_* \mathcal{C} \simeq \underline{\mathrm{Fun}}_{\underline{U}}(\underline{U} \times_{\underline{V}} \underline{U}, \mathcal{C}) \longrightarrow \mathcal{C}$ is given by restriction along the diagonal $\underline{U} \longrightarrow \underline{U} \times_{\underline{V}} \underline{U}$, the adjoint map $(\mathcal{K}_{\underline{U}})^{\underline{\triangleright}} \longrightarrow \mathcal{C}$ is a $\underline{U}$-colimit diagram. Since F is $\underline{V}$-distributive, the $\underline{V}$-functor

$$\overline{\psi} : (f_* f^* \mathcal{K})^{\underline{\triangleright}} \longrightarrow f_*(f^* \mathcal{K}^{\underline{\triangleright}}) \longrightarrow f_* \mathcal{C} \xrightarrow{F} \mathcal{D}$$

is a $\underline{V}$-colimit diagram. Since $\mathcal{K}$ is $\underline{V}$-sifted, the unit $\underline{V}$-functor $\delta : \mathcal{K} \longrightarrow f_* f^* \mathcal{K} \simeq \underline{\mathrm{Fun}}_{\underline{V}}(\underline{U}, \mathcal{K})$ is $\underline{V}$-cofinal, so $\overline{\psi \circ \delta}$ is also a $\underline{V}$-colimit diagram. But this composite is homotopic to $F \circ \overline{p}$ via the triangle identity for $f^* \dashv f_*$, proving the claim. ☐

We will use Proposition 8.19 together with Theorem 4.16 in [NS] to show e.g. that given a $\mathcal{T}$-distributive $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-category $\mathcal{C}$ (such as the G-∞-category of G-spectra equipped with the Hill–Hopkins–Ravenel norms when $\mathcal{T} = \mathbf{O}_G$), the forgetful $\mathcal{T}$-functor from the $\mathcal{T}$-∞-category of $\mathcal{T}$-commutative algebras in $\mathcal{C}$ to $\mathcal{C}$ creates all $\mathcal{T}$-sifted $\mathcal{T}$-colimits.

9. Universal constructions

In this section, we introduce a few more universal constructions in addition to that of $\mathcal{T}$-presheaves that formally adjoin smaller classes of $\mathcal{T}$-colimits. We begin with the following lemma.

9.1. **Lemma.** *Let $f : \mathcal{C} \longrightarrow \mathcal{D}$ be a functor of small ∞-categories and let $F : \mathbf{P}(\mathcal{C}) \longrightarrow \mathbf{P}(\mathcal{D})$ be the unique colimit-preserving functor that extends $j \circ f$. Then for every presheaf $\varphi \in \mathbf{P}(\mathcal{C})$, the induced functor*

$$\mathcal{C} \times_{\mathbf{P}(\mathcal{C})} \mathbf{P}(\mathcal{C})^{/\varphi} \longrightarrow \mathcal{D} \times_{\mathbf{P}(\mathcal{D})} \mathbf{P}(\mathcal{D})^{/F(\varphi)}$$

is cofinal.

Proof. We verify the hypotheses of Joyal's cofinality theorem. Let $\tau = [d, \gamma : j(d) \longrightarrow F(\varphi)]$ be an object of $\mathcal{D} \times_{\mathbf{P}(\mathcal{D})} \mathbf{P}(\mathcal{D})^{/F(\varphi)}$. We want to show that the ∞-category

$$\mathcal{E} := (\mathcal{C} \times_{\mathbf{P}(\mathcal{C})} \mathbf{P}(\mathcal{C})^{/\varphi}) \times_{(\mathcal{D} \times_{\mathbf{P}(\mathcal{D})} \mathbf{P}(\mathcal{D})^{/F(\varphi)})} (\mathcal{D} \times_{\mathbf{P}(\mathcal{D})} \mathbf{P}(\mathcal{D})^{/F(\varphi)})_{\tau/}$$

[25] Using the compatibility of the parametrized join with restriction [Sha21, Lem. 4.4], the canonical map $(f'_* \mathcal{K})^{\underline{\triangleright}} \xrightarrow{\text{can}} f'_*(\mathcal{K}^{\underline{\triangleright}})$ is defined to be the adjoint to $\epsilon^{\underline{\triangleright}} : (f'^* f'_* \mathcal{K})^{\underline{\triangleright}} \longrightarrow \mathcal{K}^{\underline{\triangleright}}$ for ϵ the counit of the adjunction $f'^* \dashv f'_*$.

is weakly contractible. Consider the commutative diagram

$$\begin{array}{ccccc}
\mathcal{E} & \xrightarrow{G'} & (\mathcal{D} \times_{\mathbf{P}(\mathcal{D})} \mathbf{P}(\mathcal{D})^{/F(\varphi)})_{\tau/} & & \\
\downarrow{\scriptstyle \pi'} & & \downarrow{\scriptstyle \pi} & & \\
\mathcal{D}_{d/} \times_{\mathcal{D}} (\mathcal{C} \times_{\mathbf{P}(\mathcal{C})} \mathbf{P}(\mathcal{C})^{/\varphi}) & \xrightarrow{G} & \mathcal{D}_{d/} \times_{\mathcal{D}} (\mathcal{D} \times_{\mathbf{P}(\mathcal{D})} \mathbf{P}(\mathcal{D})^{/F(\varphi)}) & \longrightarrow & \mathcal{D}_{d/} \\
\downarrow & & \downarrow & & \downarrow \\
\mathcal{C} \times_{\mathbf{P}(\mathcal{C})} \mathbf{P}(\mathcal{C})^{/\varphi} & \longrightarrow & \mathcal{D} \times_{\mathbf{P}(\mathcal{D})} \mathbf{P}(\mathcal{D})^{/F(\varphi)} & \longrightarrow & \mathcal{D}.
\end{array}$$

Observe that since $F(\varphi) \simeq \operatorname{colim}(\mathcal{D} \times_{\mathbf{P}(\mathcal{D})} \mathbf{P}(\mathcal{D})^{/F(\varphi)} \longrightarrow \mathbf{P}(\mathcal{D}))$ and $\operatorname{Map}_{\mathbf{P}(\mathcal{D}))}(j(d), -) : \mathbf{P}(\mathcal{D}) \longrightarrow \mathbf{Spc}$ preserves colimits, we have that $\mathcal{D}_{d/} \times_{\mathcal{D}} (\mathcal{D} \times_{\mathbf{P}(\mathcal{D})} \mathbf{P}(\mathcal{D})^{/F(\varphi)})$ is weakly homotopy equivalent to $F(\varphi)(d)$. Likewise, since F preserves colimits, the functor G is a weak homotopy equivalence. By Lemma 9.2, the functor π is a Kan fibration. By right properness of the Quillen model structure on simplicial sets, we deduce that G' is a weak homotopy equivalence, hence W is weakly contractible. □

9.2. **Lemma.** *Let $\psi : X \longrightarrow Y$ be a right fibration and let $p : K \longrightarrow X$ be a functor. Then the induced functor*

$$X_{p/} \longrightarrow Y_{\psi p/} \times_Y X$$

is a Kan fibration.

Proof. Let $n > 0$ and $\iota : A = \Lambda^n_i \longrightarrow B = \Delta^n$ be a horn inclusion. We need to solve the lifting problem

$$\begin{array}{ccc}
A & \longrightarrow & X_{p/} \\
\downarrow{\scriptstyle \iota} & \nearrow & \downarrow \\
B & \longrightarrow & Y_{\psi p/} \times_Y X
\end{array}
\quad \text{which transposes to} \quad
\begin{array}{ccc}
K \star A \bigcup_A B & \longrightarrow & X \\
\downarrow{\scriptstyle \iota'} & \nearrow & \downarrow{\scriptstyle \psi} \\
K \star B & \longrightarrow & Y.
\end{array}$$

If $i < n$ so that ι is left anodyne, then by [Lur09, Lem. 2.1.2.3], ι' is inner anodyne, and if $i > 0$ so that ι is right anodyne, then by the opposite of [Lur09, Lem. 2.1.2.4], ι' is right anodyne. Therefore, the dotted lift exists. □

9.3. **Definition.** Let $\mathcal{C}$ be a $\mathcal{T}$-∞-category. We define the *fiberwise $\mathcal{T}$-∞-category of presheaves of* $\mathcal{C}$ to be the full subcategory

$$\underline{\mathbf{P}}^{\mathrm{fb}}_{\mathcal{T}}(\mathcal{C}) \subset \underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})$$

whose fiber over each object $t \in \mathcal{T}$ is the full subcategory $\mathbf{P}(\mathcal{C}_t)$ of $\underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})_t \simeq \mathbf{P}(\mathcal{C}^{\mathrm{v}}_{\underline{t}})$, embedded via left Kan extension along the fully faithful inclusion $\mathcal{C}^{\mathrm{op}}_t \subset \mathcal{C}^{\mathrm{vop}}_{\underline{t}}$.

9.4. **Remark.** In Definition 9.3, we note that $\underline{\mathbf{P}}^{\mathrm{fb}}_{\mathcal{T}}(\mathcal{C})$ is a full $\mathcal{T}$-subcategory of $\underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})$, i.e., it is a sub-cocartesian fibration over $\mathcal{T}^{\mathrm{op}}$. Indeed, the existence of the $\mathcal{T}$-Yoneda embedding $j_{\mathcal{T}}$ as a $\mathcal{T}$-functor implies that for any morphism $\alpha : s \longrightarrow t$ in $\mathcal{T}$, the diagram

$$\begin{array}{ccccc}
\mathcal{C}_t & \longrightarrow & \mathcal{C}^{\mathrm{v}}_{\underline{t}} & \xrightarrow{j} & \underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})_t \simeq \mathbf{P}(\mathcal{C}^{\mathrm{v}}_{\underline{t}}) \\
\downarrow{\scriptstyle \alpha^*} & & & & \downarrow{\scriptstyle \overline{\alpha}^*} \\
\mathcal{C}_s & \longrightarrow & \mathcal{C}^{\mathrm{v}}_{\underline{s}} & \xrightarrow{j} & \underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})_s \simeq \mathbf{P}(\mathcal{C}^{\mathrm{v}}_{\underline{s}})
\end{array}$$

commutes, where $\overline{\alpha}^*$ is given by restriction along $\mathcal{C}^{\mathrm{vop}}_{\underline{s}} \longrightarrow \mathcal{C}^{\mathrm{vop}}_{\underline{t}}$. Since the inclusions $\mathbf{P}(\mathcal{C}_t) \subset \mathbf{P}(\mathcal{C}^{\mathrm{v}}_{\underline{t}})$ and $\mathbf{P}(\mathcal{C}_s) \subset \mathbf{P}(\mathcal{C}^{\mathrm{v}}_{\underline{s}})$ along with $\overline{\alpha}^*$ are colimit-preserving, we have a factorization of the outer rectangle as

$$\begin{array}{ccccc}
\mathcal{C}_t & \xrightarrow{j} & \mathbf{P}(\mathcal{C}_t) & \longrightarrow & \underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})_t \simeq \mathbf{P}(\mathcal{C}^{\mathrm{v}}_{\underline{t}}) \\
\downarrow{\scriptstyle \alpha^*} & & \downarrow{\scriptstyle \overline{\alpha}^*|_{\mathbf{P}(\mathcal{C}_t)}} & & \downarrow{\scriptstyle \overline{\alpha}^*} \\
\mathcal{C}_s & \xrightarrow{j} & \mathbf{P}(\mathcal{C}_s) & \longrightarrow & \underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})_s \simeq \mathbf{P}(\mathcal{C}^{\mathrm{v}}_{\underline{s}}),
\end{array}$$

which both establishes the claim and also identifies $\overline{\alpha}^*|_{\mathbf{P}(\mathcal{C}_t)}$ with the prolongation of $j \circ \alpha^*$ obtained via the universal property of $\mathbf{P}(\mathcal{C}_t)$. The $\mathcal{T}$-Yoneda embedding then restricts to a $\mathcal{T}$-functor $j^{\mathrm{fb}}_{\mathcal{T}} : \mathcal{C} \longrightarrow \underline{\mathbf{P}}^{\mathrm{fb}}_{\mathcal{T}}(\mathcal{C})$.

9.5. **Definition.** Let $\mathcal{K}$ be a $\mathcal{T}$-∞-category. Then $\mathcal{K}$ is *cofinal-constant* (*cc*) if for all morphisms $\alpha : s \longrightarrow t$ in $\mathcal{T}$, the restriction functor $\alpha^* : \mathcal{T}_t \longrightarrow \mathcal{T}_s$ is cofinal.

We say that a $\mathcal{T}$-∞-category $\mathcal{C}$ is *cc* $\mathcal{T}$-*cocomplete* if $\mathcal{C}$ strongly admits all cc $\mathcal{T}$-colimits. If $\mathcal{C}$ and $\mathcal{D}$ are cc $\mathcal{T}$-cocomplete, we will let $\underline{\mathrm{Fun}}^{cc}_{\mathcal{T}}(\mathcal{C}, \mathcal{D})$ denote the full $\mathcal{T}$-subcategory of $\underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{C}, \mathcal{D})$ whose fiber over each $t \in \mathcal{T}$ is spanned by those $\mathcal{T}^{/t}$-functors that strongly preserve all cc $\mathcal{T}^{/t}$-colimits.

More generally, if $\mathcal{K}$ is a collection of small simplicial sets, then we have analogous definitions of $\mathcal{K}$-cc $\mathcal{T}$-∞-categories, $\mathcal{K}$-cc $\mathcal{T}$-cocompleteness and $\underline{\mathrm{Fun}}^{\mathcal{K}\text{-cc}}_{\mathcal{T}}(\mathcal{C}, \mathcal{D})$, where we suppose that the collection of $\mathcal{T}$-diagrams in question are cofinal-constant and have fibers in $\mathcal{K}$.

9.6. **Proposition.** *Let $\mathcal{C}$ be a $\mathcal{T}$-∞-category. Then $\mathcal{C}$ is cc $\mathcal{T}$-cocomplete if and only if $\mathcal{C}$ strongly admits all constant $\mathcal{T}$-colimits. Similarly, if $\mathcal{C}$ and $\mathcal{D}$ are cc $\mathcal{T}$-cocomplete, then a $\mathcal{T}$-functor $F : \mathcal{C} \longrightarrow \mathcal{D}$ strongly preserves all cc $\mathcal{T}$-colimits if and only if F_t preserves all colimits for all $t \in \mathcal{T}$.*

Proof. We prove the first assertion about $\mathcal{C}$; the second assertion about F will then follow immediately. The 'only if' implication is obvious. Conversely, suppose $\mathcal{C}$ strongly admits all constant $\mathcal{T}$-colimits. Let $t \in \mathcal{T}$ and let $\mathcal{K}$ be a cc $\mathcal{T}^{/t}$-∞-category. We have the $\mathcal{T}^{/t}$-functor

$$\psi : \mathcal{K}_t \times (\mathcal{T}^{/t})^{\mathrm{op}} \longrightarrow \mathcal{K}$$

given as the cocartesian extension of the inclusion of the fiber $\mathcal{K}_t \subset \mathcal{K}$ over the initial object $\mathrm{id}_t \in (\mathcal{T}^{/t})^{\mathrm{op}}$. By assumption, for all morphisms $\alpha : s \longrightarrow t$ in $\mathcal{T}$, the functor $\psi_\alpha \simeq \alpha^* : \mathcal{K}_t \longrightarrow \mathcal{K}_s$ is cofinal, so by [Sha21, Thm. 6.7], for each $\mathcal{T}^{/t}$-functor $f : \mathcal{K} \longrightarrow \mathcal{C}_{\underline{t}}$, the induced $\mathcal{T}$-functor $\psi^* : \mathcal{C}^{(f, \mathcal{T}^{/t})/} \longrightarrow \mathcal{C}^{(f\psi, \mathcal{T}^{/t})/}$ is an equivalence. In particular, $\mathcal{C}^{(f, \mathcal{T}^{/t})/}$ admits a $\mathcal{T}^{/t}$-initial object if and only if $\mathcal{C}^{(f\psi, \mathcal{T}^{/t})/}$ does. Therefore, f extends to a $\mathcal{T}^{/t}$-colimit diagram if and only if $f\psi$ does, which completes the proof. □

Recall that $\mathcal{C}$ strongly admits all constant $\mathcal{T}$-colimits if and only if its fibers admit all colimits and its pushforward functors preserve all colimits. For example, $\underline{\mathbf{P}}^{\mathrm{fb}}_{\mathcal{T}}(\mathcal{C})$ strongly admits all constant $\mathcal{T}$-colimits, so by Proposition 9.6, $\underline{\mathbf{P}}^{\mathrm{fb}}_{\mathcal{T}}(\mathcal{C})$ is cc $\mathcal{T}$-cocomplete.

9.7. **Proposition.** *Let $\mathcal{C}$ be a small $\mathcal{T}$-∞-category and let $\mathcal{D}$ be cc $\mathcal{T}$-cocomplete. Then for any $\mathcal{T}$-functor $f : \mathcal{C} \longrightarrow \mathcal{D}$, the $\mathcal{T}$-left Kan extension F of f along $j^{\mathrm{fb}}_{\mathcal{T}}$ exists. Moreover, restriction along $j^{\mathrm{fb}}_{\mathcal{T}}$*

$$(j^{\mathrm{fb}}_{\mathcal{T}})^* : \underline{\mathrm{Fun}}^{cc}_{\mathcal{T}}(\underline{\mathbf{P}}^{\mathrm{fb}}_{\mathcal{T}}(\mathcal{C}), \mathcal{D}) \longrightarrow \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{C}, \mathcal{D})$$

implements an equivalence of $\mathcal{T}$-∞-categories, with inverse given by $\mathcal{T}$-left Kan extension.

Proof. For any $\varphi \in \underline{\mathbf{P}}^{\mathrm{fb}}_{\mathcal{T}}(\mathcal{C})_t \simeq \mathbf{P}(\mathcal{C}_t)$, note that by Lemma 9.1

$$\mathcal{C} \times_{\underline{\mathbf{P}}^{\mathrm{fb}}_{\mathcal{T}}(\mathcal{C})} \underline{\mathbf{P}}^{\mathrm{fb}}_{\mathcal{T}}(\mathcal{C})^{/\underline{\varphi}} = \mathcal{C} \times_{\underline{\mathbf{P}}^{\mathrm{fb}}_{\mathcal{T}}(\mathcal{C})} \mathrm{Ar}_{\mathcal{T}}(\underline{\mathbf{P}}^{\mathrm{fb}}_{\mathcal{T}}(\mathcal{C})) \times_{\underline{\mathbf{P}}^{\mathrm{fb}}_{\mathcal{T}}(\mathcal{C})} \underline{\varphi} \longrightarrow \underline{\varphi} \xrightarrow{\simeq} (\mathcal{T}^{/t})^{\mathrm{op}}$$

is a cofinal-constant $\mathcal{T}^{/t}$-∞-category. Therefore, by the pointwise formula for $\mathcal{T}$-left Kan extensions [Sha21, Thm. 10.3], $F = (j^{\mathrm{fb}}_{\mathcal{T}})_! f$ exists and is computed by $F_t \simeq j_! f_t$, so F_t preserves all colimits. Furthermore, given a $\mathcal{T}$-functor $G : \underline{\mathbf{P}}^{\mathrm{fb}}_{\mathcal{T}}(\mathcal{C}) \longrightarrow \mathcal{D}$ such that G_t preserves colimits for all $t \in \mathcal{T}$, since $j_! j^* G_t \xrightarrow{\simeq} G_t$ it follows that $(j^{\mathrm{fb}}_{\mathcal{T}})_!(j^{\mathrm{fb}}_{\mathcal{T}})^* G \xrightarrow{\simeq} G$ from the pointwise formula. By the same logic as [Sha21, Cor. 10.7], we thus obtain a $\mathcal{T}$-adjunction

$$(j^{\mathrm{fb}}_{\mathcal{T}})_! : \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{C}, \mathcal{D}) \rightleftarrows \underline{\mathrm{Fun}}_{\mathcal{T}}(\underline{\mathbf{P}}^{\mathrm{fb}}_{\mathcal{T}}(\mathcal{C}), \mathcal{D}) : (j^{\mathrm{fb}}_{\mathcal{T}})^*$$

in which $(j^{\mathrm{fb}}_{\mathcal{T}})_!$ is $\mathcal{T}$-fully faithful with essential image $\underline{\mathrm{Fun}}^{cc}_{\mathcal{T}}(\underline{\mathbf{P}}^{\mathrm{fb}}_{\mathcal{T}}(\mathcal{C}), \mathcal{D})$. □

9.8. **Variant.** Let $\mathcal{C}$ be a small $\mathcal{T}$-∞-category. For a collection $\mathcal{K}$ of small simplicial sets, let $\underline{\mathbf{P}}^{\mathcal{K}\text{-fb}}_{\mathcal{T}}(\mathcal{C}) \subset \underline{\mathbf{P}}^{\mathrm{fb}}_{\mathcal{T}}(\mathcal{C})$ be the full subcategory whose fiber over each $t \in \mathcal{T}$ is given by $\mathbf{P}^{\mathcal{K}}(\mathcal{C}_t) \subset \mathbf{P}(\mathcal{C}_t)$ [Lur09, Prop. 5.3.6.2], and let $j^{\mathcal{K}\text{-fb}}_{\mathcal{T}}$ denote the factorization of the $\mathcal{T}$-Yoneda embedding through $\underline{\mathbf{P}}^{\mathcal{K}\text{-fb}}_{\mathcal{T}}(\mathcal{C})$. Then by the universal property of $\mathbf{P}^{\mathcal{K}}(-)$, $\underline{\mathbf{P}}^{\mathcal{K}\text{-fb}}_{\mathcal{T}}(\mathcal{C})$ is a sub-cocartesian fibration of $\underline{\mathbf{P}}^{\mathrm{fb}}_{\mathcal{T}}(\mathcal{C})$ and hence a $\mathcal{T}$-∞-category. Note that the proof of [Lur09, Prop. 5.3.6.2] shows that for a $\mathcal{K}$-cocomplete ∞-category $\mathcal{D}$, the equivalence $\mathrm{Fun}^{\mathcal{K}}(\mathbf{P}^{\mathcal{K}}(\mathcal{C}_t), \mathcal{D}) \xrightarrow{\simeq} \mathrm{Fun}(\mathcal{C}_t, \mathcal{D})$ implemented by restriction has inverse given by left Kan extension. Thus, by the same proof as in Proposition 9.7, we see that if $\mathcal{D}$ is a $\mathcal{T}$-∞-category that is $\mathcal{K}$-cc $\mathcal{T}$-cocomplete, we have an $\mathcal{T}$-adjunction

$$(j^{\mathcal{K}\text{-fb}}_{\mathcal{T}})_! : \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{C}, \mathcal{D}) \rightleftarrows \underline{\mathrm{Fun}}_{\mathcal{T}}(\underline{\mathbf{P}}^{\mathcal{K}\text{-fb}}_{\mathcal{T}}(\mathcal{C}), \mathcal{D}) : (j^{\mathcal{K}\text{-fb}}_{\mathcal{T}})^*$$

in which $(j^{\mathcal{K}\text{-fb}}_{\mathcal{T}})_!$ is $\mathcal{T}$-fully faithful with essential image $\underline{\mathrm{Fun}}^{\mathcal{K}\text{-cc}}_{\mathcal{T}}(\underline{\mathbf{P}}^{\mathcal{K}\text{-fb}}_{\mathcal{T}}(\mathcal{C}), \mathcal{D})$.

9.9. **Definition.** If $\mathcal{K}$ is the collection of sifted resp. κ-filtered simplicial sets, we will write $\underline{\mathbf{P}}^{\Sigma}_{\mathcal{T}}(\mathcal{C})$ and $j^{\Sigma}_{\mathcal{T}}$ resp. $\underline{\mathbf{Ind}}^{\kappa}_{\mathcal{T}}(\mathcal{C})$ and $j^{\kappa}_{\mathcal{T}}$ for $\underline{\mathbf{P}}^{\mathcal{K}\text{-fb}}_{\mathcal{T}}(\mathcal{C})$ and $j^{\mathcal{K}\text{-fb}}_{\mathcal{T}}$. If $\kappa = \omega$, we will also write $\underline{\mathbf{Ind}}_{\mathcal{T}}(\mathcal{C})$.

For the following lemma, note that if $\mathcal{T}$ is orbital and $\mathcal{E}$ is an ∞-category that admits finite products, then $\underline{\mathcal{E}}_T$ admits finite $\mathcal{T}$-products in view of [Sha21, Prop. 5.6] and the pointwise formula for right Kan extension.

9.10. **Lemma.** *Suppose that $\mathcal{T}$ is an orbital ∞-category. Let $\mathcal{C}$ be a $\mathcal{T}$-∞-category that admits finite $\mathcal{T}$-products and let $\mathcal{E}$ be an ∞-category that admits finite products. Then under the equivalence*

$$(-)^{\dagger} : \mathrm{Fun}_{\mathcal{T}}(\mathcal{C}, \underline{\mathcal{E}}_{\mathcal{T}}) \xrightarrow{\simeq} \mathrm{Fun}(\mathcal{C}, \mathcal{E})$$

of [Sha21, Prop. 3.10], *a $\mathcal{T}$-functor $F : \mathcal{C} \longrightarrow \underline{\mathcal{E}}_{\mathcal{T}}$ preserves finite $\mathcal{T}$-products if and only if $F^{\dagger} : \mathcal{C} \longrightarrow \mathcal{E}$ sends cartesian edges to equivalences and $F^{\dagger}|_{\mathcal{C}_t}$ preserves finite products for all $t \in \mathcal{T}$. Moreover, if $\mathcal{T}$ admits a final object $*$, then $(-)^{\dagger}$ restricts to an equivalence $\mathrm{Fun}^{\times}_{\mathcal{T}}(\mathcal{C}, \underline{\mathcal{E}}_{\mathcal{T}}) \xrightarrow{\simeq} \mathrm{Fun}^{\times}(\mathcal{C}_*, \mathcal{E})$.*

Proof. For the first statement, first note that $F : \mathcal{C} \longrightarrow \underline{\mathcal{E}}_{\mathcal{T}}$ preserves finite products fiberwise if and only if for all $\alpha : s \longrightarrow t$ in $\mathcal{T}$, $\mathrm{ev}_{\alpha} F_t : \mathcal{C}_t \longrightarrow \mathcal{E}_{\mathcal{T}/t} \longrightarrow \mathcal{E}$ preserves finite products. But since $\mathrm{ev}_{\alpha} F_t \simeq \mathrm{ev}_{\mathrm{id}_s} F_s \alpha^*$, this occurs if and only if $F^{\dagger}|_{\mathcal{C}_t}$ preserves finite products for all $t \in \mathcal{T}$. Furthermore, by definition $F^{\dagger}$ inverts cartesian edges if and only if for all $\alpha : s \longrightarrow t$ in $\mathcal{T}$ and $x \in \mathcal{C}_s$, the natural map $(F_t \alpha_* x)(\mathrm{id}_t) \xrightarrow{\simeq} (\alpha_* F_s x)(\mathrm{id}_t)$ is an equivalence. This shows the 'only if' implication. Now let $\beta : u \longrightarrow t$ be any morphism and write $s \times_t u \simeq \coprod_{i \in I} o_i$ for $o_i \in \mathcal{T}$ and a finite set I. For each o_i, let $\alpha_i : o_i \longrightarrow u$ and $\beta_i : o_i \longrightarrow s$ denote the implicit maps, so that $\beta^* \alpha_* x \simeq \prod_{i \in I} \alpha_{i*} {\beta_i}^* x$ by our assumption that $\mathcal{C}$ admits finite $\mathcal{T}$-products. If we suppose that F preserves finite products fiberwise and $F^{\dagger}$ inverts cartesian edges, we then have

$$\begin{aligned}(F_t \alpha_* x)(\beta) &\simeq (F_u \beta^* \alpha_* x)(\mathrm{id}_u) \simeq \prod_{i \in I} (F_u \alpha_{i*} \beta_i^* x)(\mathrm{id}_u) \simeq \prod_{i \in I} (\alpha_{i*} \beta_i^* F_s)(\mathrm{id}_u) \\ &\simeq (\beta^* \alpha_* F_s x)(\mathrm{id}_u) \simeq (\alpha_* F_s x)(\beta),\end{aligned}$$

which shows the 'if' implication.

To prove the second statement, suppose now that $\mathcal{T}$ has a final object $*$. First note that if we let W denote the set of cartesian edges in $\mathcal{C}$, then the composite $\mathcal{C}_* \longrightarrow \mathcal{C} \longrightarrow \mathcal{C}[W^{-1}]$ is an equivalence of ∞-categories in view of [Lur09, Cor. 3.3.4.3]. Now let $G : \mathcal{C} \longrightarrow \mathcal{E}$ be a functor that inverts W and suppose $G|_{\mathcal{C}_*}$ preserves finite products. For any $t \in \mathcal{T}$, let $\alpha_t : t \longrightarrow *$ denote the unique morphism. If $\prod_{i \in I} x_i$ is a finite product in $\mathcal{C}_t$, then we have a cartesian edge $\prod_{i \in I} \alpha_{t*} x_i \longrightarrow \prod_{i \in I} x_i$ in $\mathcal{C}$ lifting α_t since α_{t*} is a right adjoint, hence $G(\prod_{i \in I} x_i) \simeq \prod_{i \in I} G(x_i)$ and the claim is proven. □

9.11. **Theorem.** *Suppose that $\mathcal{T}$ is an orbital ∞-category and let $\mathcal{C}$ be a $\mathcal{T}$-∞-category. Suppose that $\mathcal{C}$ admits finite $\mathcal{T}$-coproducts. Then the following statements obtain:*

(1) We have an equality

$$\underline{\mathbf{P}}^{\Sigma}_{\mathcal{T}}(\mathcal{C}) = \underline{\mathrm{Fun}}^{\times}_{\mathcal{T}}(\mathcal{C}^{\mathrm{vop}}, \underline{\mathbf{Spc}}_{\mathcal{T}})$$

as full $\mathcal{T}$-subcategories of $\underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})$.

(2) The inclusion $\underline{\mathbf{P}}^{\Sigma}_{\mathcal{T}}(\mathcal{C}) \subset \underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})$ strongly preserves $\mathcal{T}$-sifted $\mathcal{T}$-colimits and admits a $\mathcal{T}$-left adjoint L such that $j^{\Sigma}_{\mathcal{T}} \simeq L \circ j_{\mathcal{T}}$.

(3) $\underline{\mathbf{P}}^{\Sigma}_{\mathcal{T}}(\mathcal{C})$ is $\mathcal{T}$-cocomplete, $j^{\Sigma}_{\mathcal{T}}$ preserves finite $\mathcal{T}$-coproducts, and if $\mathcal{D}$ is any $\mathcal{T}$-cocomplete $\mathcal{T}$-∞-category, then restriction along $j^{\Sigma}_{\mathcal{T}}$ implements an equivalence

$$\underline{\mathrm{Fun}}^{L}_{\mathcal{T}}(\underline{\mathbf{P}}^{\Sigma}_{\mathcal{T}}(\mathcal{C}), \mathcal{D}) \xrightarrow{\simeq} \underline{\mathrm{Fun}}^{\sqcup}_{\mathcal{T}}(\mathcal{C}, \mathcal{D})$$

with inverse given by $\mathcal{T}$-left Kan extension.

Similarly, if $\mathcal{C}$ strongly admits $\mathcal{T}$-κ-small $\mathcal{T}$-colimits, then:

(1) $\underline{\mathbf{Ind}}^{\kappa}_{\mathcal{T}}(\mathcal{C})$ equals the full $\mathcal{T}$-subcategory $\underline{\mathrm{Fun}}^{\kappa\text{-lex}}_{\mathcal{T}}(\mathcal{C}^{\mathrm{vop}}, \underline{\mathbf{Spc}}_{\mathcal{T}})$ of $\underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})$ whose fiber over $t \in \mathcal{T}$ is spanned by those $\mathcal{T}^{/t}$-presheaves that strongly preserve $\mathcal{T}^{/t}$-κ-small $\mathcal{T}^{/t}$-limits.

(2) The inclusion $\underline{\mathbf{Ind}}^{\kappa}_{\mathcal{T}}(\mathcal{C}) \subset \underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})$ strongly preserves $\mathcal{T}$-κ-filtered $\mathcal{T}$-colimits and admits a $\mathcal{T}$-left adjoint L such that $j^{\kappa}_{\mathcal{T}} \simeq L \circ j_{\mathcal{T}}$.

(3) $\underline{\mathbf{Ind}}^{\kappa}_{\mathcal{T}}(\mathcal{C})$ is $\mathcal{T}$-cocomplete, $j^{\kappa}_{\mathcal{T}}$ strongly preserves $\mathcal{T}$-κ-small $\mathcal{T}$-colimits, and if $\mathcal{D}$ is any $\mathcal{T}$-cocomplete $\mathcal{T}$-∞-category, then restriction along $j^{\kappa}_{\mathcal{T}}$ implements an equivalence

$$\underline{\mathrm{Fun}}^{L}_{\mathcal{T}}(\underline{\mathbf{Ind}}^{\kappa}_{\mathcal{T}}(\mathcal{C}), \mathcal{D}) \xrightarrow{\simeq} \underline{\mathrm{Fun}}^{\kappa\text{-rex}}_{\mathcal{T}}(\mathcal{C}, \mathcal{D})$$

with inverse given by $\mathcal{T}$-left Kan extension.

Proof. In both cases, (1) is an immediate consequence of Lemma 9.10 (together with the dual of Theorem 8.6 in the second instance). Given Theorem 8.15, Theorem 8.11, and Variant 9.8, the rest of the statements then follow formally as in the proof of [Lur09, Prop. 5.5.8.10] and [Lur09, Prop. 5.5.8.15]. ☐

10. Appendix: Promonoidal Day convolution

We record the following important technical lemma on flat fibrations and apply it to construct $\mathcal{O}$-*promonoidal Day convolution* with respect to a base ∞-operad $\mathcal{O}$.

10.1. **Lemma.** *Let $\mathcal{B}$ be an ∞-category with a factorization system $(\mathscr{L},\mathscr{R})$ and let $p : \mathcal{X} \longrightarrow \mathcal{B}$ be a categorical fibration. Let $\mathrm{Ar}^L(\mathcal{B})$ denote the full subcategory of $\mathrm{Ar}(\mathcal{B})$ on those arrows in $\mathscr{L}$ and consider the functor*

$$\pi = \mathrm{ev}_0 \circ \mathrm{pr}_1 : \mathrm{Ar}^L(\mathcal{B}) \times_{\mathcal{B}} \mathcal{X} \longrightarrow \mathcal{B}.$$

Suppose that

1. *For every edge $e : a \longrightarrow b$ in $\mathscr{L}$ and $x \in \mathcal{X}$ such that $p(x) = a$, there exists a p-cocartesian edge $x \longrightarrow y$ covering e.*
2. *The pullback $\mathcal{X}_R = \mathcal{X} \times_{\mathcal{B}} \mathcal{B}_R \longrightarrow \mathcal{B}_R$ is a flat categorical fibration, where $\mathcal{B}_R \subset \mathcal{B}$ denotes the wide subcategory on those morphisms in $\mathscr{R}$.*

Then π is a flat categorical fibration.

Proof. We apply the criterion of [Lur17, Prop. B.3.2] to show flatness. In other words, if we let $\sigma_0 = [a_0 \to b_0 \to c_0]$ be a 2-simplex in $\mathcal{B}$ and let

$$\left(\begin{array}{ccc} a_0 & \longrightarrow & c_0 \\ \downarrow{\scriptstyle \alpha} & & \downarrow{\scriptstyle \gamma} \\ a_1 & \longrightarrow & c_1 \end{array} , \; x \longrightarrow z \right)$$

be an edge in $\mathrm{Ar}^L(\mathcal{B}) \times_{\mathcal{B}} \mathcal{X}$ covering $a_0 \longrightarrow c_0$ via π, then we need to show that

$$\begin{aligned}(\mathrm{Ar}^L(\mathcal{B}) \times_{\mathcal{B}} \mathcal{X})^{(\alpha,x)//(\gamma,z)}_{b_0} &:= \{\sigma_0\} \times_{\mathcal{B}^{a_0//c_0}} (\mathrm{Ar}^L(\mathcal{B}) \times_{\mathcal{B}} \mathcal{X})^{(\alpha,x)//(\gamma,z)} \\ &\simeq \mathrm{Ar}^L(\mathcal{B})^{\alpha//\gamma}_{b_0} \times_{\mathcal{B}^{a_1//c_1}} \mathcal{X}^{x//z}\end{aligned}$$

is weakly contractible.

As we noted in Proposition 3.5(1), the functor $\mathrm{ev}_0 : \mathrm{Ar}^L(\mathcal{B}) \longrightarrow \mathcal{B}$ is a cartesian fibration, with ev_0-cartesian edges given by morphisms $f \longrightarrow g$ such that the edge $f(1) \longrightarrow g(1)$ is in $\mathscr{R}$. Therefore, we may identify the full subcategory of $\mathrm{Ar}^L(\mathcal{B})^{\alpha//\gamma}_{b_0}$ spanned by the final objects with that spanned by objects of the form

$$\begin{array}{ccccc} a_0 & \longrightarrow & b_0 & \longrightarrow & c_0 \\ \downarrow{\scriptstyle \alpha} & & \downarrow{\scriptstyle \beta} & & \downarrow{\scriptstyle \gamma} \\ a_1 & \longrightarrow & b_1 & \longrightarrow & c_1 \end{array}$$

in which $b_1 \longrightarrow c_1$ is in $\mathscr{R}$. Fix such a choice of final object $\sigma_\bullet$, and let

$$\theta : \Delta^1 \times \mathrm{Ar}^L(\mathcal{B})^{\alpha//\gamma}_{b_0} \longrightarrow \mathrm{Ar}^L(\mathcal{B})^{\alpha//\gamma}_{b_0}$$

be the natural transformation recording the essentially unique homotopy of the identity functor to the constant functor at $\sigma_\bullet$ (i.e., the unit transformation of the associated localization functor). Also let

$$\theta' : \mathrm{Ar}^L(\mathcal{B})^{\alpha//\gamma}_{b_0} \longrightarrow \mathrm{Fun}(\Delta^1, \mathrm{Ar}^L(\mathcal{B})^{\alpha//\gamma}_{b_0}) \longrightarrow \mathrm{Fun}'(\Delta^1, \mathcal{B}^{a_1//c_1})$$

be the composite of the adjoint to θ and evaluation at the target. Here, Fun' denotes the full subcategory on objects $\tau = [a_1 \to b_1' \to b_1 \to c_1]$ with $d_1 \tau = \sigma_1$ and such that $b_1' \longrightarrow b_1$ is in $\mathscr{L}$; in other words, $d_0 \tau$ is the essentially unique factorization of $b_1' \longrightarrow c_1$ furnished by $(\mathscr{L},\mathscr{R})$. We then define a natural transformation

$$\eta : \Delta^1 \times \mathrm{Ar}^L(\mathcal{B})^{\alpha//\gamma}_{b_0} \times_{\mathcal{B}^{a_1//c_1}} \mathcal{X}^{x//z} \longrightarrow \mathrm{Ar}^L(\mathcal{B})^{\alpha//\gamma}_{b_0} \times_{\mathcal{B}^{a_1//c_1}} \mathcal{X}^{x//z}$$

as θ on the first factor and the adjoint to

$$\mathrm{Ar}^L(\mathcal{B})^{\alpha//\gamma}_{b_0} \times_{\mathcal{B}^{a_1//c_1}} \mathcal{X}^{x//z} \xrightarrow{(\theta',\mathrm{id})} \mathrm{Fun}'(\Delta^1, \mathcal{B}^{a_1//c_1}) \times_{\mathrm{ev}_0, \mathcal{B}^{a_1//c_1}} \mathcal{X}^{x//z} \xrightarrow{P} \mathrm{Fun}(\Delta^1, \mathcal{X}^{x//z})$$

on the second factor, where P is the cocartesian pushforward functor that on objects is given by

$$([a_1 \to b_1' \xrightarrow{e} b_1 \to c_1],\, x \to y \to z) \rightsquigarrow [x \to e_! y \to z]$$

and rigorously defined as in [Sha21, Lem. 2.23].

Let $L = \eta_1$ and observe that the essential image of L is $\mathcal{X}^{x//z}_{b_1} := \{\sigma_1\} \times_{\mathcal{B}^{a_1//c_1}} \mathcal{X}^{x//z}$. It is then straightforward to show that η satisfies condition (3) of [Lur09, Prop 5.2.7.4] so that L is a localization functor. In particular, it suffices to show that $\mathcal{X}^{x//z}_{b_1}$ is weakly contractible. Moreover, after choosing a $(\mathscr{L}, \mathscr{R})$-factorization $[a_1 \xrightarrow{e} a_1' \to b_1]$, we have a p-cocartesian lift $\overline{e} : x \longrightarrow x'$ of e by assumption (1), and by the universal property of $\overline{e}$ we have an equivalence

$$\mathcal{X}^{x//z}_{b_1} \simeq (\mathcal{X}_R)^{x'//z}_{a_1'}.$$

But hypothesis (2) then ensures that $(\mathcal{X}_R)^{x'//z}_{a_1'}$ is weakly contractible, which completes the proof. □

Now let $\mathcal{O}^\otimes$ be an ∞-operad and consider the factorization system given by the inert and active edges (cf. [Lur17, Def. 2.1.2.3] and [Lur17, Prop. 2.1.2.4]). Let $\mathcal{O}^\otimes_{act} \subset \mathcal{O}^\otimes$ be the wide subcategory on the active edges.

10.2. **Definition.** Let $p : \mathcal{C}^\otimes \longrightarrow \mathcal{O}^\otimes$ be a fibration of ∞-operads. We say that p *exhibits* $\mathcal{C}^\otimes$ *as a* $\mathcal{O}$-*promonoidal* ∞-*category* if the restricted functor $p_{act} : \mathcal{C}^\otimes_{act} \longrightarrow \mathcal{O}^\otimes_{act}$ is flat.

10.3. **Example.** Suppose that $\mathcal{C}^\otimes$ is a $\mathcal{O}$-monoidal ∞-category, so that its structure map p is a cocartesian fibration. $\mathcal{C}^\otimes$ is then $\mathcal{O}$-promonoidal since cocartesian fibrations are flat [Lur17, Exm. B.3.4].

The following example was pointed out to us by Harpaz and shows that our earlier definition of symmetric promonoidal given as [BGS20, Def. 1.4] was too restrictive.

10.4. **Example.** There exists examples of $\mathcal{O}$-promonoidal ∞-categories $(\mathcal{C}^\otimes, p)$ such that p itself is not flat. For instance, consider the ∞-operad $\mathrm{MCom}^\otimes$ that parametrizes modules over commutative algebras (cf. [HNP19, 4.3]). Then $\mathrm{MCom}^\otimes$ is symmetric promonoidal, but $p : \mathrm{MCom}^\otimes \longrightarrow \mathbf{F}_*$ is not flat. Indeed, let $\langle n \rangle = \{1, ..., n, +\}$ and consider the composition of maps of pointed finite sets

$$h : \langle 3 \rangle \xrightarrow{f} \langle 2 \rangle \xrightarrow{g} \langle 1 \rangle$$

where $f(1) = 1, f(2) = 2, f(3) = 2$ and $g(1) = 1, g(2) = +$. Let m be the object of MCom representing the module factor and consider the inert edge $e : (m, m, m) \longrightarrow m$ over h. Then e doesn't factor over $h = g \circ f$, so p is not flat.

10.5. **Remark.** Let $(\mathcal{C}^\otimes, p)$ be a $\mathcal{O}$-promonoidal ∞-category. Then if $\mathcal{C}^\otimes$ is moreover *corepresentable* in the sense that p is locally cocartesian, we claim that p is cocartesian so that $\mathcal{C}^\otimes$ is $\mathcal{O}$-monoidal. Indeed, by [BGS20, Prop. 1.5] we see that p_{act} is cocartesian, and using the inert-active factorization system on $\mathcal{C}^\otimes$ together with the decomposition of mapping spaces in $\mathcal{C}^\otimes$ ensured by the definition of an ∞-operad [Lur17, Def. 2.1.1.10(2)], it is not difficult to check that p itself is cocartesian.

We now generalize Lurie's construction of Day convolution [Lur17, Thm. 2.2.6.2], which assumed that $\mathcal{C}^\otimes$ was $\mathcal{O}$-monoidal. Let $\mathrm{Ar}^{ne}(\mathcal{O}^\otimes)$ denote the full subcategory of $\mathrm{Ar}(\mathcal{O}^\otimes)$ on the inert edges.

10.6. **Theorem-Construction.** Let $(\mathcal{C}^\otimes, p)$ be a $\mathcal{O}$-promonoidal ∞-category. Consider the span of marked simplicial sets

$$(\mathcal{O}^\otimes, \mathrm{Ne}) \xleftarrow{\mathrm{ev}_0} (\mathrm{Ar}^{ne}(\mathcal{O}^\otimes) \times_{\mathrm{ev}_1, \mathcal{O}^\otimes, p} \mathcal{C}^\otimes, \mathrm{Ne}) \xrightarrow{\mathrm{pr}_{\mathcal{C}^\otimes}} (\mathcal{C}^\otimes, \mathrm{Ne})$$

where the middle marking consists of those edges in $\mathrm{Ar}^{ne}(\mathcal{O}^\otimes) \times_{\mathcal{O}^\otimes} \mathcal{C}^\otimes$ whose source in $\mathcal{O}^\otimes$ is inert and whose projection to $\mathcal{C}^\otimes$ is inert. Then the functor

$$(\mathrm{ev}_0)_* \circ (\mathrm{pr}_{\mathcal{C}^\otimes})^* : \mathbf{sSet}^+_{/(\mathcal{C}^\otimes, \mathrm{Ne})} \longrightarrow \mathbf{sSet}^+_{/(\mathcal{O}^\otimes, \mathrm{Ne})}$$

is right Quillen with respect to the operadic model structures of [Lur17, Prop. 2.1.4.6]. For a fibration $\mathcal{D}^{\otimes} \longrightarrow \mathcal{C}^{\otimes}$ of ∞-operads, we then define the *p-operadic coinduction* of $\mathcal{D}^{\otimes}$ to be

$$(\mathrm{Nm}_p \mathcal{D})^{\otimes} := (\mathrm{ev}_0)_* (\mathrm{pr}_{\mathcal{C}^{\otimes}})^* (\mathcal{D}^{\otimes}, \mathrm{Ne}).$$

For a fibration $\mathcal{D}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ of ∞-operads, we define the *Day convolution* (of $\mathcal{C}^{\otimes}$ with $\mathcal{D}^{\otimes}$ over $\mathcal{O}^{\otimes}$) to be

$$\widetilde{\mathrm{Fun}}_{\mathcal{O}}(\mathcal{C}, \mathcal{D})^{\otimes} := (\mathrm{Nm}_p p^* \mathcal{D})^{\otimes}.$$

Proof. It suffices to verify the hypotheses of [Lur17, Thm. B.4.2]. For (1), ev_0 is flat by Lemma 10.1. The remainder of the proof is now identical to that of [Lur17, Prop. 2.2.6.20(a)]; the only additional point to note is that the verification of (5) only uses that $\mathcal{C}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ admits p-cocartesian lifts over *inert* edges in the base. □

10.7. **Remark.** It follows readily from the definition that the underlying ∞-category of the Day convolution $\widetilde{\mathrm{Fun}}_{\mathcal{O}}(\mathcal{C}, \mathcal{E})^{\otimes}$ is equivalent to the pairing construction $\widetilde{\mathrm{Fun}}_{\mathcal{O}}(\mathcal{C}, \mathcal{E})$ (Theorem-Construction 4.2 with $\mathcal{T} = *$).

Given Theorem-Construction 10.6, all the usual properties of Day convolution with this extra generality in the source variable then hold; we will give a comprehensive treatment of the parametrized theory in [NS]. In particular, we have that for any fibration $\mathcal{D}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ of ∞-operads, the identity section

$$\iota : (\mathcal{D}^{\otimes} \times_{\mathcal{O}^{\otimes}} \mathcal{C}^{\otimes}, \mathrm{Ne}) \hookrightarrow (\mathcal{D}^{\otimes} \times_{\mathcal{O}^{\otimes}} \mathrm{Ar}^{ne}(\mathcal{O}^{\otimes}) \times_{\mathcal{O}^{\otimes}} \mathcal{C}^{\otimes}, \mathrm{Ne})$$

is a homotopy equivalence in $\mathbf{sSet}^+_{/(\mathcal{C}^{\otimes}, \mathrm{Ne})}$, so for all fibrations $\mathcal{E}^{\otimes} \longrightarrow \mathcal{C}^{\otimes}$ of ∞-operads, restriction along ι induces an equivalence of ∞-categories

$$\mathbf{Alg}_{\mathcal{D}/\mathcal{O}}(\mathrm{Nm}_p \mathcal{E}) \xrightarrow{\simeq} \mathbf{Alg}_{\mathcal{D} \times_{\mathcal{O}} \mathcal{C}/\mathcal{C}}(\mathcal{E}).$$

Thus, we may think of the class of $\mathcal{O}$-promonoidal ∞-categories as singling out the *exponentiable* fibrations of ∞-operads over $\mathcal{O}^{\otimes}$.

PARAMETRIZED HIGHER CATEGORY THEORY AND HIGHER ALGEBRA: EXPOSÉ IV – STABILITY WITH RESPECT TO AN ORBITAL ∞-CATEGORY

DENIS NARDIN

ABSTRACT. In this paper we develop a theory of stability for G-categories (presheaf of categories on the orbit category of G), where G is a finite group. We give a description of Mackey functors as G-commutative monoids exploit it to characterize G-spectra as the G-stabilization of G-spaces. As an application of this we provide an alternative proof of a theorem by Guillou and May. The theory here is developed in the more general setting of orbital categories.

CONTENTS

1. INTRODUCTION

It is often said that spectra are the same as homology theories. This is strictly speaking wrong when homology theories are interpreted as valued in graded abelian groups, due to the presence of phantom maps. Luckily, Goodwillie calculus provides us with an equivalence between spectra and linear functors from finite pointed spaces to spaces (that is space-valued homology theories). This allows us to state a universal property for the category of spectra: it is the universal source of a linear functor to spaces ([21, Pr. 1.4.2.22]).

One would imagine that a similar statement should be true for G-spectra, where G is a finite group. The category of G-spectra is not, however, the universal source of linear functors to G-spaces (that would be spectral presheaves over the orbit category of G). It has been an important insight in the solution to the Kervaire invariant one problem by Hill, Hopkins, and Ravenel ([18]) that in G-spectra one should ask for a stronger form of additivity: they should not only turn coproducts into products, but also coproducts indexed by a finite G-set into the corresponding product. This is merely a form of Atiyah duality for finite G-sets, but a highly suggestive one.

In order to speak of indexed products and coproducts it is necessary to be able to remember the notion of objects with an H-action for every subgroup H of G. So we need to move from the notion of ∞-category to the notion of G-∞-category, which is a presheaf of categories over $\mathbf{O}_G$, the orbit category of G. This sends G/H to the ∞-category of objects corresponding to the subgroup H (e.g. H-spaces, H-spectra etc.) and encodes all the functoriality of restriction to subgroups (corresponding to the map $G/H \longrightarrow G/K$ for $H \subseteq K$) and of twisting the action by conjugation (corresponding to the isomorphism of G/H with G/gHg^{-1} in $\mathbf{O}_G$). The general theory of (co)limits indexed by a G-∞-category has been developed in [26]. We will briefly summarize the necessary results in section 2.

Once the notion of G-(co)limit has been set up, one can try to mimic the whole theory of additive and stable ∞-categories in this equivariant setting. This works nicely and provides us with a universal property for the G-∞-category of G-spectra: it is the universal recipient of a G-linear functor from the G-∞-category of finite G-spaces (cf. theorem 7.4).

1.1. **Theorem.** *For any G-category with finite G-colimits C the G-functor Ω^∞ : $\mathbf{Sp}^G \longrightarrow \mathbf{Top}^G$ induces an equivalence*

$$\mathrm{Fun}_G^{G-\mathrm{rex}}(C, \underline{\mathbf{Sp}}^G) \longrightarrow \mathrm{Lin}_G(C, \underline{\mathbf{Top}}_G)$$

between the category of G-functors $C \longrightarrow \underline{\mathbf{Sp}}^G$ preserving finite G-colimits and the category of G-linear G-functors $C \longrightarrow \underline{\mathbf{Top}}_G$.

Another important result in the same spirit is the identification of connective spectra with group-like commutative monoids in spaces, as done in [25]. This too has an equivariant analogue (cf. corollary A.4.1). In fact it turns out that G-commutative monoids are the same thing as product-preserving functors from the effective Burnside category of [2]. This explains the ubiquity of Mackey functors in equivariant homotopy theory and allows us to give an alternative proof of [17, Th. 0.1], identifying orthogonal G-spectra with spectral Mackey functors (see appendix A).

Two important predecessors of this paper are [14] and [15]. In the first a description of G-spectra as enriched functors from G-spaces to G-spaces is provided for a general compact Lie group, while the second contains a characterization of G-spectra as functors in term of an excisivity condition for a finite group G. While the approach taken here is different, the intuition behind it is very similar.

In this paper we will work in the general setting of atomic orbital categories (see section 2). Examples of atomic orbital categories beyond the orbit category of a (pro)finite group are an ∞-groupoid (thus recovering the theory of [23]), the cyclonic orbit category ([8, Df. 1.10]) and the global orbit category for finite groups (the full subcategory of $\mathbf{O}_{gl}$ defined in [24, Cn. 8.32] spanned by completely universal finite subgroups of $\mathcal{L}$). One important non-example is the orbit ∞-category of a compact Lie group. This is due to the lack of a good notion of finite G-set stable under restriction to subgroups when G is compact Lie. The reader uninterested in such generality can safely substitute $\mathbf{O}_G$ every time T appears in this paper.

Acknowledgments: This paper is part of a joint project with Clark Barwick, Emanuele Dotto, Saul Glasman and Jay Shah. Many of the ideas and details of the present paper arose first during conversations with them. Other papers in this project are [4], [3], [26], [7], [1], [5], [13], [12], and [11]. I would like to thank Mark Behrens for help navigating the models for G-spectra in appendix A. We also want to thank all the other past and present participants to the Bourbon seminar for the incredibly stimulating environment: Lukas Brantner, Peter Haine, Marc Hoyois, Akhil Mathew and Tomer Schlank.

2. Preliminaries on equivariant (co)limits

2.1. We will be using extensively the theory of T-∞-categories for a general base category T, developed in [3] and [26]. In this section we will recall the most important results.

Motivated by the discussion of G-categories in the introduction, we want to study presheaves of ∞-categories over T. However, a different model for those turns out to be more convenient (e.g. allowing us to state results like theorem 2.8). To describe it we will make use of the following foundational result of the theory of ∞-categories (cfr. [20, Th. 3.2.0.1] and [20, Sec. 3.3.2]):

2.2. **Theorem.** *There is a cocartesian fibration $\mathcal{Z} \longrightarrow \mathbf{Cat}_\infty$ such that for every ∞-category S there is an equivalence between $\mathrm{Fun}(S, \mathbf{Cat}_\infty)$ and the ∞-category of cocartesian fibrations over S, sending $F : S \longrightarrow \mathbf{Cat}_\infty$ to the pullback of $\mathcal{Z} \longrightarrow \mathbf{Cat}_\infty$ along F.*

2.3. **Definition.** Motivated by the previous result, we let a T-∞-*category* to be a cocartesian fibration over T^{op}. A T-*functor* between two T-∞-categories is simply a map of cocartesian fibrations (that is a map of simplicial sets over T^{op} that sends cocartesian arrows to cocartesian arrows). Using the simplicial nerve of [20, Df. 1.1.5.5] we can form the ∞-category of T-∞-categories.

2.4. **Notation.** If C is a T-∞-category and $e : t \longrightarrow t'$ is an edge of T, we denote the pushforward functor $C_{t'} \longrightarrow C_t$ by δ_e or $\delta_{t/t'}$.

2.5. **Definition.** For any ∞-category T, the ∞-category $\mathbf{F}_T$ of *finite T-sets* is the full subcategory of the category of presheaves on T spanned by finite coproducts of representables. It satisfies the following universal property: for any ∞-category D with all finite coproducts the forgetful functor

$$\mathrm{Fun}^{\amalg}(\mathbf{F}_T, D) \longrightarrow \mathrm{Fun}(T, D)$$

is an equivalence, where the left hand side is the category of functors preserving finite coproducts. There is a functor $\mathrm{Orbit} : \mathbf{F}_T \longrightarrow \mathbf{F}$ (where $\mathbf{F} = \mathbf{F}_{\Delta^0}$ is the category of finite sets) sending every finite T-set to the set of summands.

For any finite T-set U there is a T-∞-category $\mathbf{U}$, called the *category of points* of U, which as a simplicial set over T^{op} is defined by

$$\mathbf{U} = T^{op} \times_{\mathbf{F}_T^{op}} (\mathbf{F}_T^{op})_{U/} \ .$$

This is the left fibration classified by the functor sending V to the space of arrows $[V \longrightarrow U]$.

2.6. **Construction.** If C, D are two T-∞-categories, there exists a T-∞-category $\underline{\mathrm{Fun}}_T(C, D)$ classified by the functor

$$b \mapsto \mathrm{Fun}_{T_{/b}}(C|_{T_{b/}}, D|_{T_{b/}})$$

There is an obvious evaluation T-functor

$$C \times_{T^{op}} \underline{\mathrm{Fun}}_T(C, D) \longrightarrow D$$

2.7. **Definition.** For every ∞-category C we want to construct a T-∞-category $\underline{C}_T$ classified by the functor $b \mapsto \mathrm{Fun}(T^{op}_{/b}, C)$. This is the *$T$-$\infty$-category of T-objects in C*. As a simplicial set over T^{op} it is given by

$$\mathrm{Mor}_{/T^{op}}(K, \underline{C}_T) = \mathrm{Mor}(K \times_{T^{op}} \mathrm{Fun}(\Delta^1, T^{op}), C)$$

where $\mathrm{Fun}(\Delta^1, T^{op})$ lies above T^{op} with the evaluation at 0. This is a cocartesian fibration thanks to [20, Co. 3.2.2.13].

When $T = \mathbf{O}_G$ and $C = \mathbf{Top}$, this is the cocartesian fibration classified by the functor sending G/H to the ∞-category of genuine H-spaces (that is presheaves of spaces over $\mathbf{O}_H$). One of the pleasant features of the model of T-∞-categories we are using is that the T-∞-category of T-objects has a simple universal property:

2.8. **Theorem.** *Suppose T an ∞-category, C a T-∞-category, and D an ∞-category. Then there is a natural equivalence*

$$\mathrm{Fun}_T(C, \underline{D}_T) \simeq \mathrm{Fun}(C, D)\,.$$

In particular, by [20, Th. 3.2.0.1]*, the ∞-category $\mathrm{Fun}_T(C, \underline{\mathbf{Cat}_\infty}_T)$ is equivalent to the ∞-category associated to the simplicial category of cocartesian fibrations over C and under this equivalence left fibrations correspond to functors whose image lies in $\underline{\mathbf{Top}}_T$.*

2.9. **Definition.** A T-adjunction between two T-∞-categories C and D is an adjunction $FG : C \leftrightarrows D$ between the two total categories such that F and G are T-functors (that is they send cocartesian arrows to cocartesian arrows) and unit and counit lie above the identity natural transformation of the identity functor on T. This is the same thing as a relative adjunction in the sense of [21, Sec. 7.3.2] such that both functors are T-functors. Note that the left adjoint in a relative adjunction is is automatically a T-functor, but this is not true for the right adjoint.

2.10. **Definition.** Precomposition with the structure map $C \longrightarrow T^{op}$ induces a diagonal T-functor

$$\Delta : D \cong \underline{\mathrm{Fun}}_T(T, D) \longrightarrow \underline{\mathrm{Fun}}_T(C, D)\,.$$

When this T-functor has a left T-adjoint we say that D has all C-indexed T-colimits. Similarly, if it has a right T-adjoint we say that D has all C-indexed T-limits. If a T-∞-category D has all C-indexed T-colimits (respectively T-limits) for every small T-category C we say that D is T-cocomplete (respectively T-complete).

A T-colimit indexed by a T-category of the form $\mathrm{pr}_2 : K \times T^{op} \longrightarrow T^{op}$ for K an ∞-category is called a fiberwise T-colimit. A T-colimit indexed by the category of points of a finite T-set is called a finite T-coproduct. A T-∞-category is said to be *pointed* if it has both a T-initial and a T-terminal object (that are cocartesian sections of the structure map that fiberwise select the initial and the terminal object respectively) and the canonical comparison map is an equivalence.

The following proposition summarizes the results on T-(co)limits from [26] that will be needed in this paper.

2.11. **Proposition.** *Let C be a T-∞-category.*

- *C has all T-colimits indexed by $K \times T^{op}$ if and only if for every $b \in T$ the fiber C_b has all colimits indexed by K and for every edge $e : b \longrightarrow b'$ in T the pushforward functor $\delta_e : C_{b'} \longrightarrow C_b$ preserves colimits indexed by K.*

- *Suppose $\mathbf{F}_T$ has all fiber products (that is T is orbital, cf. Df. 4.1). Then C has all (finite) T-coproducts if and only if the following two conditions are satisfied*
  (1) *for every $b \in T$ the fiber C_b has all (finite) coproducts and for every edge $e : b \longrightarrow b'$ the pushforward δ_e preserves (finite) coproducts;*
  (2) *For every edge $e : b \longrightarrow b'$ the pushforward δ_e has a left adjoint $\coprod_e$ satisfying the Beck-Chevalley condition: for every pair of edges $e : b \longrightarrow b'$ and $e' : b'' \longrightarrow b'$ the canonical base change natural transformation of functors from $C_{b''}$ to C_b*
  $$\delta_e \coprod_{e'} \longrightarrow \coprod_{o \in \mathrm{Orbit}(b \times_{b'} b'')} \coprod_{pr_1} \delta_{pr_2}$$
  is an equivalence, where $pr_1 : o \longrightarrow b$ and $pr_2 : o \longrightarrow b'$ are the restrictions to o of the two projections from $b \times_{b'} b''$.
- *C has all T-colimits if and only if it has all fiberwise colimits and all finite T-coproducts.*

Similar statements hold for T-limits. When T-products exist the right adjoint of δ_e will be denoted by $\prod_e$.

2.12. **Definition.** There is also a notion of T-Kan extension, defined exactly as for the T-(co)limit: if we have a T-functor $j : I \longrightarrow J$ there is a T-functor induced by precomposition with j:

$$j^* : \underline{\mathrm{Fun}}_T(J, D) \longrightarrow \underline{\mathrm{Fun}}_T(I, D)\,.$$

If j^* has a left T-adjoint we denote it by $j_!$ and call it the *left T-Kan extension* along j. Similarly, when j^* has a right T-adjoint we call it the *right T-Kan extension j_**.

The proof of the following proposition can be found in [26].

2.13. **Proposition.** *Let C be a T-∞-category with all T-colimits. Then for every map of small T-∞-categories $j : I \longrightarrow I'$ the left Kan extension along j*

$$j_! : \underline{\mathrm{Fun}}_T(I, C) \longrightarrow \underline{\mathrm{Fun}}_T(I', C)$$

exists. Similarly for T-limits and the right Kan extension j_*.

2.14. **Notation.** A T-functor is said to be *fiberwise left exact*, *T-left exact*, *fiberwise right exact*, *T-right exact* if it preserves finite fiberwise limits, finite T-limits, finite fiberwise colimits and finite T-colimits respectively. We will denote the full T-∞-subcategories of $\underline{\mathrm{Fun}}_T(C, D)$ preserving certain (co)limits will be denoted as in the following list:

- $\underline{\mathrm{Fun}}_T^{T-\mathrm{lex}}(C, D)$: finite T-colimits;
- $\underline{\mathrm{Fun}}_T^{fb-\mathrm{lex}}(C, D)$: finite fiberwise colimits;
- $\underline{\mathrm{Fun}}_T^{\amalg}(C, D)$: finite T-coproducts;
- $\underline{\mathrm{Fun}}_T^{T-\mathrm{rex}}(C, D)$: finite T-limits;
- $\underline{\mathrm{Fun}}_T^{fb-\mathrm{rex}}(C, D)$: finite fiberwise limits;
- $\underline{\mathrm{Fun}}_T^{\times}(C, D)$: finite T-products.

3. Fiberwise stability

3.1. **Recollection.** If C is an ∞-category with finite colimits and D is an ∞-category with finite limits a functor $F : C \longrightarrow D$ is called *linear* if it sends the initial object of C to the terminal object of D and pushout squares in C to pullback squares in D (this functors are called *pointed excisive* in [21]). In [21, Pr. 1.4.2.13] it is proven that a pointed functor is linear if and only if the natural transformation $F \longrightarrow \Omega F \Sigma$ is an equivalence. The full subcategory of $\mathrm{Fun}(C, D)$ spanned by linear functors is denoted $\mathrm{Lin}(C, D)$.

3.2. **Definition.** Let C, D T-∞-categories and assume that C has all finite fiberwise colimits and D has all finite fiberwise limits. We say that a T-functor $F : C \longrightarrow D$ is *fiberwise linear* if the restriction on the fiber $F_b : C_b \longrightarrow D_b$ is linear for every $b \in T$. We denote the full T-subcategory of $\underline{\mathrm{Fun}}_T(C, D)$ spanned by fiberwise linear functors with $\underline{\mathrm{Lin}}_T(C, D)$.

3.3. First we want to show that, if C is T-pointed, $\mathrm{Lin}_T(C, D)$ is a localization of the subcategory $\mathrm{Fun}_{T,*}(C, D)$ of functors sending the zero object to the terminal object in each fiber. To do so we introduce two additional functors $\Sigma_T : C \longrightarrow C$ and $\Omega_T : D \longrightarrow D$ which are the pushout (respectively pullback) of the diagrams

$$\begin{array}{ccc} id_C & \longrightarrow & * \\ \downarrow & & \\ * & & \end{array} \quad \text{and} \quad \begin{array}{ccc} & & * \\ & & \downarrow \\ * & \longrightarrow & id_D \end{array} .$$

Since fiberwise linearity can be checked fiberwise it is clear that a functor $F \in \mathrm{Fun}_{T,*}(C, D)$ is in $\mathrm{Lin}(C, D)$ if and only if the canonical map $F \longrightarrow \Omega_T F \Sigma_T$ is an equivalence.

3.4. **Lemma.** *Suppose that C is a pointed T-category. Then the ∞-category $\mathrm{Lin}_T(C, D)$ is stable.*

Proof. It is clear that $\mathrm{Lin}_T(C, D)$ has finite limits and that it is pointed. If we show that Ω is an equivalence we are done by proposition 1.4.2.24 of [21]. But Ω is just postcomposition with $\Omega_T : D \longrightarrow D$ and then it is obvious that precomposition with $\Sigma_T : C \longrightarrow C$ is an inverse. □

3.5. **Definition.** We say that a T-∞-category D with all finite fiberwise limits and colimits is fiberwise stable if all fibers D_b are stable.

3.6. **Construction.** If C is a T-∞-category we want to construct a fiberwise stabilization, that is the universal source of a fiberwise linear T-functor to C. Let $\mathcal{E}(D)$ be the simplicial set over T^{op} such that

$$\mathrm{Mor}_{/T^{op}}(K, \mathcal{E}(D)) \cong \mathrm{Mor}_{/T^{op}}(K \times \mathbf{Top}_*^{fin}, D)$$

(this is an instance of the pairing construction of [20, Cor. 3.2.2.13]). The fiber over $b \in T^{op}$ is the category $\mathrm{Fun}(\mathbf{Top}_*^{fin}, D_b)$.

We let $\underline{\mathbf{Sp}}_T(D)$ be the simplicial subset of $\mathcal{E}(D)$ consisting of all simplices whose vertices are linear functors $\mathbf{Top}_*^{fin} \longrightarrow D_b$. This is the same simplicial set denoted by $Stab(D)$ in [21, Cn. 6.2.2.2]. It comes equipped with a natural map of simplicial sets $\Omega^\infty : \underline{\mathbf{Sp}}_T(D) \longrightarrow D$ over T^{op} that on vertices is evaluation at S^0.

3.7. **Proposition.** *The map $\underline{\mathbf{Sp}}_T(D) \longrightarrow T^{op}$ is a fiberwise stable T-∞-category.*

Moreover the natural functor $\Omega^\infty \colon \underline{\mathbf{Sp}}_T(D) \longrightarrow D$ is a fiberwise left exact T-functor and for every pointed T-∞-category C with finite T-colimits the induced map

$$\underline{\mathrm{Fun}}_T^{fb-\mathrm{rex}}(C, \underline{\mathbf{Sp}}_T(D)) \longrightarrow \underline{\mathrm{Lin}}_T(C, D)$$

is an equivalence of categories.

Proof. From [20, Cor. 3.2.2.13] it follows immediately that $\mathcal{E}(D)$ is a cocartesian fibration whose cocartesian edges are those maps $(\Delta^1)^\sharp \times (\mathbf{Top}_*^{fin})^\flat \longrightarrow D^\natural$ that are marked. So to prove that $\underline{\mathbf{Sp}}_T(D) \longrightarrow T^{op}$ is a cocartesian fibration we need only to prove that it contains all cocartesian edges whose source is in it (that is, that $\underline{\mathbf{Sp}}_T(D)$ is closed under pushforward). But, by our description of cocartesian edges, the pushforward functor along an edge $e : b \longrightarrow b'$ of $\mathcal{E}$ is given by

$$(\delta_e)_* : \mathcal{E}_{b'} = \mathrm{Fun}(\mathbf{Top}_*^{fin}, D_{b'}) \longrightarrow \mathcal{E}_b = \mathrm{Fun}(\mathbf{Top}_*^{fin}, D_b)\,,$$

that is postcomposition with the pushforward in D. Since the pushforward in D preserves finite limits by definition, $(\delta_e)_*$ preserves linear functors and so $\underline{\mathbf{Sp}}_T(D)$ is a T-∞-category.

Note that the fiber of $\underline{\mathbf{Sp}}_T(D)$ over $b \in T$ is exactly the stabilization of the fiber D_b and that the pushforward functors between fibers of $\underline{\mathbf{Sp}}_T(D)$ are the functors induced by the pushforward between the fibers of D. So the cocartesian fibration $\underline{\mathbf{Sp}}_T(D)$ has all finite fiberwise limits and colimits and is fiberwise stable. Moreover the functor $\underline{\mathbf{Sp}}_T(D) \longrightarrow D$ is a T-functor preserving T-limits.

Finally let us prove the universal property. Since the fibers of

$$\underline{\mathrm{Fun}}_T^{fb-\mathrm{lex}}(C, \underline{\mathbf{Sp}}_T(D)) \text{ and } \underline{\mathrm{Lin}}_T(C, D)$$

over $b \in T$ are

$$\mathrm{Fun}_{T_{/b}}^{fb-\mathrm{lex}}(C \times_{T^{op}} T_{b/}^{op}, \underline{\mathbf{Sp}}_{T_{/b}}(D \times_{T^{op}} T_{b/}^{op})) \text{ and } \mathrm{Lin}_{T_{/b}}(C \times_{T^{op}} T_{b/}^{op}, D \times_{T^{op}} T_{b/}^{op})$$

respectively, up to replacing T by its slice $T_{/b}$ it is enough to prove that the functor

$$(\Omega^\infty)_* : \mathrm{Fun}_T^{fb-\mathrm{lex}}(C, \underline{\mathbf{Sp}}_T(D)) \longrightarrow \mathrm{Lin}_T(C, D)$$

is an equivalence of categories (since being an equivalence can be checked on every fiber). Observe that $\mathrm{Fun}_T^{fb-\mathrm{lex}}(C, \underline{\mathbf{Sp}}_T(D))$ and $\mathbf{Sp}(\mathrm{Lin}_T(C, D))$ are the same subcategory of $\mathrm{Fun}_T(C \times \mathbf{Top}^{fin}, D)$, because both are spanned by the functors $F : C \times \mathbf{Top}_T^{fin} \longrightarrow D$ whose restriction to $C_b \times \mathbf{Top}^{fin}$ lie in $\mathrm{Fun}^{lex}(C_b, \mathbf{Sp}(D_b)) = \mathbf{Sp}(\mathrm{Lin}(C_b, D_b))$ for any $b \in T$. Then the thesis is obvious because $\mathrm{Lin}(C_b, D_b)$ is stable. □

4. Categories of finite T-sets

4.1. **Definition.** A small ∞-category T is said to be *orbital* if the category $\mathbf{F}_T$ of definition 2.5 has all pullbacks. An orbital category T is *atomic* if there are no nontrivial retracts, that is if every map with a left inverse is an equivalence.

A more in depth treatment of orbital ∞-categories can be found in [7].

4.2. **Example.** The following are examples of atomic orbital categories:

- The orbit category $\mathbf{O}_G$ of a (pro)finite group is atomic orbital;
- The category of finite sets and surjections is atomic orbital;
- In general any epiorbital category ([16, Df. 2.1]) is atomic orbital;
- All ∞-groupoids are atomic orbital categories;
- Every cosieve of an atomic orbital category is atomic orbital;
- More generally, the total category of every right fibration over an atomic orbital ∞-category is atomic orbital;
- The cyclonic orbit category of [8, Df. 1.10] is atomic orbital;
- The category of connected groupoids (that is groupoids of the form BG for a finite group G) and covering maps is atomic orbital. This is the full subcategory of the global orbit category of [24, Cn. 8.32] spanned by the completely universal finite subgroups of $\mathcal{L}$.

4.3. For the remainder of this paper, T will be a fixed atomic orbital category. We will now construct T-∞-categories of finite T-sets that will be used to parametrize the various multiplications composing the structure of a T-commutative monoid.

4.4. **Definition.** We want to construct the T-category classified by the functor $T \longrightarrow \mathbf{Cat}_\infty$ sending V to $\mathbf{F}_{T_{/V}}$. We contemplate the arrow ∞-category $\mathrm{Fun}(\Delta^1, \mathbf{F}_T)$ of the ∞-category $\mathbf{F}_T$ of finite T-sets. Since $\mathbf{F}_T$ admits all pullbacks, the target functor

$$\mathrm{Fun}(\Delta^1, \mathbf{F}_T) \longrightarrow \mathrm{Fun}(\{1\}, \mathbf{F}_T) \cong \mathbf{F}_T$$

is a cartesian fibration. We may pull it back along the fully faithful inclusion $T \hookrightarrow \mathbf{F}_T$ to obtain a cartesian fibration

$$\tau\colon \mathrm{Fun}(\Delta^1, \mathbf{F}_T) \times_{\mathrm{Fun}(\{1\}, \mathbf{F}_T)} T \longrightarrow T.$$

It is classified by the functor $T^{op} \longrightarrow \mathbf{Cat}_\infty$ that carries an orbit V to the ∞-category $\mathbf{F}_{T_{/V}}$.

We now write

$$p\colon \underline{\mathbf{F}}_T \longrightarrow T^{op}$$

for the dual cocartesian fibration $\tau^\vee$ (constructed in [9]) to the cartesian fibration τ. This is now a T-∞-category, called the T-∞-category of finite T-sets, and once again it is classified by the functor $T^{op} \longrightarrow \mathbf{Cat}_\infty$ that carries an orbit V to the nerve of the ∞-category $\mathbf{F}_{T_{/V}}$. Its objects are arrows $I = [U \longrightarrow V]$ with $U \in \mathbf{F}_T$ and $V \in T$ and an arrow $[U \longrightarrow V] \longrightarrow [U' \longrightarrow V']$ is a diagram

$$\begin{array}{ccccc} U & \longleftarrow & W & \longrightarrow & U' \\ \downarrow & & \downarrow & & \downarrow \\ V & \longleftarrow & V' & = & V' \end{array}$$

where the left square is cartesian. Composition is then defined by forming suitable pullbacks. The target functor

$$[U \longrightarrow V] \rightsquigarrow V$$

is the structure map $p\colon \underline{\mathbf{F}}_T \longrightarrow T^{op}$.

4.5. **Example.** If $T = \mathbf{O}_G$ is the orbit category of a profinite group G, then $\underline{\mathbf{F}}_G \longrightarrow \mathbf{O}_G^{op}$ is the cocartesian fibration classified by the functor sending an orbit G/H to the category of finite H-sets (under the canonical identification that sends a finite G-set over G/H to the fiber over eH).

4.6. **Example.** Suppose V is an object of T. Then there is an object

$$I(V) = [id\colon V \longrightarrow V]$$

of $\underline{\mathbf{F}}_T$, which enjoys the following property. For any object $J = [g\colon X \longrightarrow Y]$ of $\underline{\mathbf{F}}_T$, one has an equivalence

$$\mathrm{Map}_{\underline{\mathbf{F}}_T}(J, I(V)) \simeq \mathrm{Map}_T(V, Y).$$

In particular, the assignment $V \rightsquigarrow I(V)$ defines a fully faithful right adjoint to the structure map $p\colon \underline{\mathbf{F}}_T \longrightarrow T^{op}$.

4.7**.** In what follows it will be convenient to have at our disposal more general categories whose objects are finite T-sets. They will be all more easily manipulated as subcategories of the Burnside category of finite T-sets. The latter is the dual version of the main construction in [6], but we will repeat it here both because of its simplicity and because we will need to use some details in our main results.

4.8. **Construction.** Let again us consider the cartesian fibration

$$\tau\colon S_T := \mathrm{Fun}(\Delta^1, \mathbf{F}_T) \times_{\mathrm{Fun}(\{1\}, \mathbf{F}_T)} T \longrightarrow T.$$

It is also, for much easier reasons, a cocartesian fibration.

With this in mind, we now proceed to define triple structures on these ∞-categories. Denote by $\iota T \subset T$ the subcategory consisting of the equivalences of T. Then we can contemplate the triple structures

$$(T, \iota T, T) \quad \text{and} \quad (S_T, S_T \times_T \iota T, S_T).$$

It is a simple matter to see that these triple structures are adequate in the sense of [2, Df. 5.2]. We may therefore construct their effective Burnside ∞-categories, and the projection induces a functor

$$t'\colon A^{\mathit{eff}}(S_T, S_T \times_T \iota T, S_T) \longrightarrow A^{\mathit{eff}}(T, \iota T, T).$$

An object of $A^{\mathit{eff}}(S_T, S_T \times_T \iota T, S_T)$ is a morphism $[U \longrightarrow V]$ of finite T-sets in which $V \in T$. If

$$I = [U \longrightarrow V] \quad \text{and} \quad J = [X \longrightarrow Y]$$

are two objects, then a morphism $I \longrightarrow J$ of $A^{\mathit{eff}}(S_T, S_T \times_T \iota T, S_T)$ is a commutative diagram

$$\begin{array}{ccccc} U & \longleftarrow & W & \longrightarrow & X \\ \downarrow & & \downarrow & & \downarrow \\ V & \longleftarrow & Z & \xrightarrow{\sim} & Y \end{array}$$

in which the morphism $Z \xrightarrow{\sim} Y$ is an equivalence in T.

4.9. **Lemma.** *The functor t' above is both a cartesian and a cocartesian fibration. Furthermore, any morphism of $A^{\mathit{eff}}(S_T, S_T \times_T \iota T, S_T)$ represented as a commutative diagram*

$$\begin{array}{ccccc} U & \longleftarrow & W & \longrightarrow & X \\ \downarrow & & \downarrow & & \downarrow \\ V & \longleftarrow & Z & \xrightarrow{\sim} & Y \end{array}$$

is

- *t'-cartesian if the morphisms $W \xrightarrow{\sim} U$ and $W \xrightarrow{\sim} X$ are equivalences;*
- *t'-cocartesian if the left square is cartesian and $\equiv WX$ is an equivalence.*

Proof. This follows immediately from (the opposite of) the "omnibus theorem" for effective Burnside ∞-categories [2, Th. 12.2]. ☐

4.10. **Definition.** We have an inclusion $T^{op} \hookrightarrow A^{eff}(T, \iota T, T)$, which is a weak equivalence. Write

$$\underline{\mathbf{A}}^{eff}(T) := A^{eff}(S_T, S_T \times_T \iota T, S_T) \times_{A^{eff}(T,\iota T,T)} T^{op};$$

the projection $\underline{\mathbf{A}}^{eff}(T) \longrightarrow A^{eff}(S_T, S_T \times_T \iota T, S_T)$ is thus an equivalence, and the projection

$$t\colon \underline{\mathbf{A}}^{eff}(T) \longrightarrow T^{op}$$

is a cartesian and cocartesian fibration, so it is a T-∞-category.

It is classified by the functor sending $V \in T$ to the Burnside category $A^{eff}(\mathbf{F}_{T_{/V}})$.

4.11. Note that $\underline{\mathbf{F}}_T$ is naturally a T-subcategory of $\underline{\mathbf{A}}^{eff}(T)$, consisting of all objects and all morphisms such that the left square is cartesian. This is the analogue of the classical inclusion of the category $\mathbf{F}$ of finite sets inside the Burnside category of finite sets $A^{eff}(\mathbf{F})$ by considering only the egressive maps.

This can be extended to an inclusion of *pointed* finite sets $\mathbf{F}_*$ inside $A^{eff}(\mathbf{F})$ as the subcategory containing all objects and as maps the spans $[I \longleftarrow \tilde{I} \longrightarrow I']$ such that the "left leg" is an inclusion ($\tilde{I}$ under this identification corresponds to the preimage of I' under the map $I_+ \longrightarrow I'_+$, so that we can identify $\mathbf{F}_*$ with the category of finite sets and partially defined maps. It will be convenient for us to turn this into the definition of finite pointed T-sets.

4.12. **Definition.** We'll say that a map $U \longrightarrow U'$ of finite T-sets is a *summand inclusion* if there is $U'' \longrightarrow U'$ such that the map $U \amalg U'' \longrightarrow U'$ is an equivalence.

Consider the subcategory of $\underline{\mathbf{A}}^{eff}(T)$ containing all objects and whose morphisms are those diagrams

$$\begin{array}{ccccc} U & \longleftarrow & \tilde{U} & \longrightarrow & U' \\ \downarrow & & \downarrow & & \downarrow \\ V & \longleftarrow & V' & = & V' \end{array}$$

such that the arrow $\tilde{U} \longrightarrow U \times_V V'$ is a summand inclusion (this is a condition of the left square of the diagram and does not depend on the particular choice of pullback $U \times_V V'$). This subcategory contains all cocartesian morphisms of $\underline{\mathbf{A}}^{eff}(T) \longrightarrow T^{op}$ and so it is a T-subcategory. We will call it the *T-∞-category of finite pointed T-sets* and denote it by $\underline{\mathbf{F}}_{*T}$.

4.13. **Notation.** We will often decorate an object $I = [U \longrightarrow V]$ of $\underline{\mathbf{F}}_{*T}$ with a subscript $+$, to remind ourselves that we see it as living in $\underline{\mathbf{F}}_{*T}$ rather than of $\underline{\mathbf{F}}_T$ or $\underline{\mathbf{A}}(T)$. The $+$ does not have any real meaning (in our construction there are no "basepoints") and it is only a mnemonic aid. The canonical inclusion $\mathbf{F}^T \longrightarrow \mathbf{F}_*^T$ will be indicated by $(-)_+ : I \mapsto I_+$.

4.14. **Lemma.** *The cocartesian fibration $\underline{\mathbf{F}}_{*T} \longrightarrow T^{op}$ is classified by the functor sending V to the category of pointed objects in $(\mathbf{F}_T)_{V/}$.*

Moreover the canonical inclusion $(-)_+ : \underline{\mathbf{F}}_T \longrightarrow \underline{\mathbf{F}}_{*T}$ has a right T-adjoint sending $[U \longrightarrow V]$ to $[U \amalg V \longrightarrow V]$.

Proof. The fiber of $\underline{\mathbf{F}}_{*T}$ over V consists in the Burnside category of $\mathbf{F}_{T/V}$ where the egressive morphisms are the summand-inclusions. We can identify this with the category of pointed objects by sending a span

$$U \longleftarrow \tilde{U} \longrightarrow U'$$

where $U = \tilde{U} \amalg W$ to the map

$$U \amalg V \longrightarrow U' \amalg V$$

where the central map is $U \amalg V = \tilde{U} \amalg (W \amalg V) \longrightarrow U' \amalg V$, given by $\tilde{U} \longrightarrow U'$ on the first component and the structure map to V on the second component.

Now it is clear that the functor

$$[U \amalg V \longrightarrow V] \mapsto [U \amalg V \longrightarrow V]$$

is the right adjoint to the inclusion of $\mathbf{F}_{T/V}$ into pointed objects. So in order to have a T-adjunction we need only to verify that the right adjoint provided by [21, Pr. 7.3.2.6] is a T-functor, but this follows from the universality of finite coproducts in $\mathbf{F}_T$ and the fact that coproducts therein are disjoint. □

5. T-semiadditive functors and T-semiadditive categories

5.1. **Notation.** Let $I = [U \longrightarrow V] \in \underline{\mathbf{F}}_T$ and $W \in \mathrm{Orbit}(U)$, then the canonical map $W \longrightarrow U \times_V W$ must be a summand-inclusion, since it factors through an unique orbit, of which W is a retract. So we can define the *characteristic map*

$$\chi_{[W \subseteq U]} \colon I_+ \longrightarrow I(W)_+$$

(where $I(W)$ is the construction of example 4.6) as the map of pointed finite T-sets described by the following diagram

$$\begin{array}{ccccc} U & \longleftarrow & W & = & W \\ \downarrow & & \| & & \| \\ V & \longleftarrow & W & = & W \end{array}.$$

Note that this map is in $\underline{\mathbf{F}}_{*T}$ due to the fact that, thanks to the atomicity of T, the map $W \longrightarrow U \times_V W$ is a summand inclusion, since the orbit it factors through retract onto W..

5.2. **Construction.** Let C be a pointed T-∞-category with all finite T-coproducts, $I = [U \longrightarrow V] \in \underline{\mathbf{F}}_T$ and $X \in \mathrm{Fun}_T(\mathbf{U}, C)$ be a diagram. Then there is a map induced on the colimits

$$(\chi_{[W \subseteq U]})_* : \delta_{W/V} \coprod_I X \longrightarrow X_{[W \subseteq U]} .$$

above $\chi_{[W \subseteq U]}$, where $\coprod_I$ is the left adjoint to $\delta_I : C_V \cong \mathrm{Fun}_T(\mathbf{V}, C) \longrightarrow \mathrm{Fun}_T(\mathbf{U}, C)$ and $X_{[W \subseteq U]}$ is the value of X at $[W \subseteq U] \in \mathbf{U}$. We can describe it as follows: by the base change condition in proposition 2.11 we have

$$\delta_{W/V} \coprod_I X \cong \coprod_{[U \times_V W/W]} \delta_{[U \times_V W/U]} X$$

As before, the atomicity of T implies that we can write

$$U \times_V W \cong W \amalg \tilde{U}$$

where W on the right hand side is the diagonal copy. Hence

$$\delta_{W/V} \coprod_I X \cong X_{[W \longrightarrow U]} \amalg \coprod_{[\tilde{U} \longrightarrow U]} X \,.$$

So we can define a map

$$(\chi_{[W \subseteq U]})_* : \delta_{W/V} \coprod_I X \longrightarrow X_{[W \subseteq U]}$$

which is the identity on the first summand and the zero map on the other.

If D is a T-∞-category with finite T-products and $F : C \longrightarrow D$ a T-functor we will denote by $(\chi_{[W \subseteq U]})_*$ also the natural transformation

$$F\left(\coprod_I X\right) \longrightarrow \prod_{W/V} F(X)$$

obtained by adjunction on $F(\chi_{[W \subseteq U]})_*$, where $\prod_{W/V}$ is the right adjoint of $\delta_{W/V}$.

5.3. **Definition.** Let C be a pointed T-∞-category with all finite T-coproducts and D a T-∞-category with all finite T-products. Then a T-functor $F : C \longrightarrow D$ is said to be *T-semiadditive* if for every $I = [U \longrightarrow V] \in \underline{\mathbf{F}}_T$ and $X \in \mathrm{Fun}_T(\mathbf{U}, C)$ the map
(5.3.1)

$$\prod_{W \in \mathrm{Orbit}(U)} (\chi_{[W \subseteq U]})_* : F\left(\coprod_I X\right) \longrightarrow \prod_{W \in \mathrm{Orbit}(U)} \prod_{W/V} F(X_{[W \subseteq U]}) \cong \prod_I F(X)$$

is an equivalence. We will denote the T-∞-category of all T-semiadditive T-functors with $\underline{\mathrm{Fun}}_T^{\oplus}(C, D)$.

We say that a pointed T-∞-category with all finite T-products and T-coproducts is *T-semiadditive* if the identity functor is T-semiadditive. That is, if the map

$$\coprod_I X \longrightarrow \prod_I X \tag{5.3.2}$$

is an equivalence for every I-uple X.

It is clear that if $F : C \longrightarrow D$ preserves finite T-coproducts and $G : D \longrightarrow E$ is T-semiadditive then the composition GF is T-semiadditive. Similarly if F is T-semiadditive and G preserves finite T-products.

5.4. **Example.** Let C be a pointed T-∞-category with all finite T-coproducts and D an ∞-category with all finite products. Then the category of T-objects $\underline{D}_T$ has all finite T-products and a T-functor $C \longrightarrow \underline{D}_T$ is T-semiadditive if and only if the associated functor $F : C \longrightarrow D$ is such that for every $[U \longrightarrow V] \in \underline{\mathbf{F}}_T$ the map

$$F\left(\coprod_I X\right) \longrightarrow \prod_{W \in \mathrm{Orbit}(U)} F(X_{[W \subseteq U]})$$

is an equivalence. In particular if D is semiadditive (i.e. it has biproducts), then $\underline{D}_T$ is T-semiadditive.

5.5. **Example.** The T-∞-category $\mathbf{A}^{\mathit{eff}}(T)$ is T-semiadditive. In fact every fiber is semiadditive by proposition 4.3 of [2], so it is sufficient to observe that for any arrow $W \longrightarrow V$ in T the functor

$$\delta_{W/V} \colon A^{\mathit{eff}}(T_{/V}) \longrightarrow A^{\mathit{eff}}(T_{/W})$$

has well behaved left and right adjoints and the canonical comparison map is an equivalence.

5.6. **Construction.** Let C be a pointed T-∞-category with finite T-products. Then if $I = [U \longrightarrow V] \in \mathbf{F}^T$ and $X : \mathbf{U} \longrightarrow C$, let us consider for every $W \in \mathrm{Orbit}(U)$ the map of C_V

$$\eta_{[W\subseteq U]} : \coprod_{W/V} X_{[W \longrightarrow U]} \hookrightarrow \coprod_I X \longrightarrow \prod_I X .$$

This can be described as the adjoint to the map in the fiber over W

$$X_{[W\subseteq U]} \longrightarrow \delta_{W/V} \prod_{I_W} X \cong \prod_{W'\in \mathrm{Orbit}(U\times_V W)} \prod_{W'/W} X_{[W' \longrightarrow U]} ,$$

given by the identity map $X_W \longrightarrow \prod_{W'/W} X_{W'}$ when W' is the diagonal copy W in $U \times_V W$ and the zero map on the other components.

Then C being T-semiadditive is equivalent to the fact that $\{\eta_W\}_{W\in\mathrm{Orbit}(U)}$ assemble to an equivalence

$$\coprod_I X \cong \coprod_{W\in\mathrm{Orbit}(U)} \coprod_{W/V} X_{[W\subseteq U]} \xrightarrow{\coprod \eta_{[W\subseteq U]}} \prod_I X .$$

The previous remark immediately yields the following criterion for determining when a category is T-semiadditive

5.7. **Lemma.** *Let C be a pointed T-∞-category with finite products and suppose that for every $I = [U \longrightarrow V] \in \mathbf{F}^T$ there is a natural transformation*

$$\mu^I : \prod_I \Delta X \longrightarrow X$$

of functors $C_V \longrightarrow C_V$, where $\Delta : C_V \longrightarrow \mathrm{Fun}_T(\mathbf{U}, C)$ is the functor of definition 2.10, such that for every $W \in \mathrm{Orbit}(U)$ the composition

$$\mu^I \circ \eta_{[W\subseteq U]} : \coprod_{W/V} \delta_{W/V} X \longrightarrow X$$

is homotopic to the counit of the adjunction $\coprod_{W/V} \dashv \delta_{W/V}$. Then C is T-semiadditive.

Proof. We need to prove that for every $[U \longrightarrow V] \in \underline{\mathbf{F}}_T$, $X \in \mathrm{Fun}_T(\mathbf{U}, C)$ and $Y \in C_V$, the map

$$\prod_{W\in\mathrm{Orbit}(U)} (\eta_{[W\subseteq U]})^* : \mathrm{Map}_{C_V}\left(\prod_I X, Y\right) \longrightarrow \prod_{W\in\mathrm{Orbit}(U)} \mathrm{Map}_{C_V}\left(\coprod_{W/V} X_{[W\subseteq U]}, Y\right)$$

is an equivalence. But using the μ^I we can construct an inverse

$$(\mu^I_Y)_* \circ \prod_I : \prod_{W\in\mathrm{Orbit}(U)} \mathrm{Map}_{C_V}\left(\coprod_{W/V} X_{[W\subseteq U]}, Y\right) \cong \mathrm{Map}_{\mathrm{Fun}(\mathbf{U},C)}(X, \Delta Y) \longrightarrow$$

$$\longrightarrow \mathrm{Map}_{C_V}\left(\prod_I X, \prod_I \Delta I\right) \longrightarrow \mathrm{Map}_{C_V}\left(\prod_I X, Y\right) .$$

□

5.8. **Proposition.** *If C is a pointed T-∞-category with finite T-coproducts and D is a T-∞-category with finite T-products then $\underline{\mathrm{Fun}}^{\oplus}(C, D)$ is T-semiadditive*

Proof. First let us note that by I to be empty in 5.3.1 every T-semiadditive functor must send the zero object of C to the terminal object of D. Then for any additive functor F the left T-Kan extension of the restriction to the zero object of C is the constant functor at the terminal object, since the T-colimit of a constant functor at the zero object is the zero object. So, if $i : \{0\} \subseteq C$ is the inclusion of the zero object

$$\mathrm{Map}_{\mathrm{Fun}_T^{\oplus}}(*, F) = \mathrm{Map}(i_!(F|_0), F) = \mathrm{Map}(F|_0, F|_0) = *$$

Hence the constant functor at the terminal object is the zero object of $\underline{\mathrm{Fun}}_T^{\oplus}(C, D)$.

Then we need to prove that $\underline{\mathrm{Fun}}_T^{\oplus}(C, D)$ satisfies the hypothesis of the previous lemma. But this is easy: for F a T-semiadditive T-functor remember that $\left(\prod_I F\right)(-) \cong F\left(\coprod_I -\right)$ so we can choose

$$\mu^I : \left(\prod_I F\right)(-) \cong F\left(\coprod_I -\right) \longrightarrow F(-)$$

given by precomposition with the canonical map $id_C \longrightarrow \coprod_I$ provided by the universal property of the coproduct of C. Since the required identites are easily verified we are done. □

5.9. **Definition.** Let C be a T-∞-category with finite products. Then a T-commutative monoid is a T-semiadditive functor $\underline{\mathbf{F}_{*}}_T \longrightarrow C$. We will indicate the T-∞-category of T-commutative monoids in C with $\underline{\mathbf{CMon}}_T(C)$. Precomposition with the cocartesian section $I(-)_+ : T^{op} \longrightarrow \underline{\mathbf{F}_{*}}_T$ induces a T-functor

$$\underline{\mathbf{CMon}}_T(C) \longrightarrow C\,.$$

In order to prove the universal property of $\underline{\mathbf{CMon}}_T(C)$ we will need the following lemma

5.10. **Lemma.** *Let C be a pointed T-∞-category with finite T-coproducts. Then the map*

$$\mathrm{Fun}_T^{\amalg}(\underline{\mathbf{F}_{*}}_T, C) \longrightarrow C$$

given by precomposition with $I(-)_+$ is an equivalence

Proof. We can construct an inverse by sending every $c \in C_V$ to the left Kan extension of its cocartesian section $\mathbf{V} \longrightarrow C$ along $I(-)_+ : T^{op} \longrightarrow \underline{\mathbf{F}_{*}}_T$. □

5.11. **Proposition.** *Let C be a T-∞-category with finite T-products. The functor*

$$\underline{\mathbf{CMon}}_T(C) \longrightarrow C\,.$$

induced by precomposition with the cocartesian section $I(-)_+ : T \longrightarrow \mathbf{F}_*^T$ is an equivalence if and only if C is T-semiadditive.

Proof. If the map is an equivalence then C is T-semiadditive, since $\underline{\mathbf{CMon}}_T(C)$ is. Vice versa if C is T-semiadditive then

$$\underline{\mathbf{CMon}}_T(C) = \underline{\mathrm{Fun}}_T^{\oplus}(\underline{\mathbf{F}_{*}}_T, C) = \underline{\mathrm{Fun}}_T^{\amalg}(\underline{\mathbf{F}_{*}}_T, C) \longrightarrow C$$

is an equivalence by lemma 5.10. □

5.11.1. **Corollary.** *Let C be a T-∞-category with finite T-products and D a pointed T-∞-category with finite T-coproducts. Then the map*

$$\mathrm{Fun}_T^{\amalg}(D, \underline{\mathbf{CMon}}_T(C)) \longrightarrow \mathrm{Fun}_T^{\oplus}(D, C)$$

is an equivalence of categories.

Proof. Observe that

$$\mathrm{Fun}_T^{\amalg}(D, \underline{\mathbf{CMon}}_T(C)) \cong \mathrm{Fun}_T^{\oplus}(D, \underline{\mathbf{CMon}}_T(C)) \cong \underline{\mathbf{CMon}}_T(\mathrm{Fun}_T^{\oplus}(D, C))$$

where the first equivalence comes from the T-semiadditivity of $\underline{\mathbf{CMon}}_T(C)$. Since $\mathrm{Fun}_T^{\oplus}(D, C)$ is T-semiadditive the thesis follows by the previous proposition. □

6. T-commutative monoids and Mackey functors

6.1. The notion of T-commutative monoid, while being the natural generalization of Γ-space to the parametrized setting, might seem abstract and difficult to work with. The aim of this section is that in fact T-commutative monoids are just objects very familiar in equivariant homotopy theory: Mackey functors.

6.2. **Lemma.** *Let $\underline{\mathbf{F}_*^{in}}_T$ be the T-subcategory of $\underline{\mathbf{F}_*}_T$ containing all objects and all the maps represented by spans in S_T*

$$I \longleftarrow \tilde{I} \longrightarrow I'$$

where the right arrow is an equivalence. Then a functor $M : \underline{\mathbf{F}_*}_T \longrightarrow \mathbf{Top}$ is a T-commutative monoid if and only if its restriction to $\underline{\mathbf{F}_*^{in}}_T$ is a right Kan extension along $I(-)_+ : T^{op} \longrightarrow \mathbf{F}_*^T$.

Proof. Obvious from the limit description of right Kan extensions (see [20, Pr. 4.3.2.15]). □

6.3. **Lemma.** *The inclusion $j : \underline{\mathbf{F}_*}_T \longrightarrow \underline{\mathbf{A}}^{\mathit{eff}}(T)$ is a T-commutative monoid.*

Proof. Clear from the fact that $\underline{\mathbf{F}_*}_T$ contains all T-coproduct diagrams of $\underline{\mathbf{A}}^{\mathit{eff}}(T)$ and example 5.5. □

6.4. **Lemma.** *Let C be an ∞-category and let E, F, D subcategories of C such that (C, E, D) and (C, E, F) are adequate triples in the sense of* [2]*. Consider the diagram of categories*

$$\begin{array}{ccc} A^{\mathit{eff}}(C, \iota E, D) & \xrightarrow{f} & A^{\mathit{eff}}(C, E, D) \\ \downarrow{\scriptstyle g'} & & \downarrow{\scriptstyle g} \\ A^{\mathit{eff}}(C, \iota E, F) & \xrightarrow{f'} & A^{\mathit{eff}}(C, E, F) \end{array}$$

Then if a right Kan extension along g' exists so does the right Kan extension along g' and the natural transformation

$$f'^* g_* \longrightarrow g'_* f^*$$

is an equivalence.

Proof. Let us fix $I \in C$. We need to prove that the functor

$$A^{\text{eff}}(C, \iota E, D) \times_{A^{\text{eff}}(C,\iota E,F)} A^{\text{eff}}(C, \iota E, F)_{I/} \longrightarrow A^{\text{eff}}(C, E, D) \times_{A^{\text{eff}}(C,E,F)} A^{\text{eff}}(C, E, F)_{I/}$$

is coinitial. This is equivalent to the fact that for every $J \in C$ with a map from I the category

$$\left(A^{\text{eff}}(C, \iota E, D) \times_{A^{\text{eff}}(C,\iota E,F)} A^{\text{eff}}(C, \iota E, F)_{I/}\right) \times_{\left(A^{\text{eff}}(C,E,D) \times_{A^{\text{eff}}(C,E,F)} A^{\text{eff}}(C,E,F)_{I/}\right)} \left(A^{\text{eff}}(C, E, D) \times_{A^{\text{eff}}(C,E,F)} A^{\text{eff}}(C, E, F)_{I/}\right)_{/J}$$

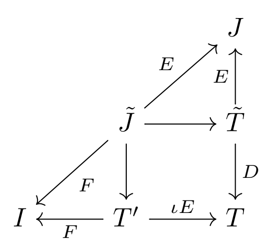
is weakly contractible. Let us start naming names. We have a fixed map $I \longrightarrow J$ in $A^{\text{eff}}(C, E, F)$. This correspond to a span

$$I \xleftarrow{F} \tilde{J} \xrightarrow{E} J\,,$$

where we decorate every arrow with the subcategory it lives in. Now an object of our category is $T \in T$ together with an arrow in $A^{\text{eff}}(C, \iota E, F)$ from I and an arrow in $A^{\text{eff}}(C, E, D)$ to J. These correspond to spans

$$I \xleftarrow{F} T' \xrightarrow{\iota E} T \qquad \text{and} \qquad T \xleftarrow{D} \tilde{T} \xrightarrow{E} J\,.$$

The last piece of data needed is an homotopy of their composition with the given map $I \longrightarrow J$, that is a diagram



where the central square is cartesian. But this is equivalent to the map $\tilde{J} \longrightarrow \tilde{T}$ being an equivalence. Summing up, an object of our category is a factorization of $\tilde{J} \longrightarrow I$

$$\tilde{J} \xrightarrow{D} T \xrightarrow{F} I\,.$$

Moreover a similar analysis on higher simplices shows that this is the opposite of the category of factorizations. It is easy to see that $\tilde{J} \xrightarrow{=} \tilde{J} \longrightarrow I$ is a terminal object for this category, which is then weakly contractible. ☐

6.5. **Theorem.** *Let C be a T-∞-category with finite T-limits. Precomposition with the inclusion $j : \underline{\mathbf{F}}_{*T} \longrightarrow \underline{\mathbf{A}}^{\text{eff}}(T)$ induces an equivalence*

$$\underline{\text{Fun}}_T^{\times}(\underline{\mathbf{A}}^{\text{eff}}(T), C) \longrightarrow \underline{\mathbf{CMon}}_T(C)\,.$$

We denote the category on the left hand side by $\underline{\mathbf{Mack}}^T(C)$ and call it the T-∞-category of T-Mackey functors valued in C.

Proof. Let $\underline{\mathrm{Psh}}_T(C)$ be the T-presheaf T-∞-category of C. Then, by the full faithfulness of the T-Yoneda embedding (see [3, Th. 10.4]) we have a pullback square

$$\begin{array}{ccc} \underline{\mathrm{Fun}}^{\times}_T(\underline{\mathbf{A}}^{eff}(T), C) & \longrightarrow & \underline{\mathbf{CMon}}_T(C) \\ \downarrow & & \downarrow \\ \underline{\mathrm{Fun}}^{\times}_T(\underline{\mathbf{A}}^{eff}(T), \mathrm{Psh}_T(C)) & \longrightarrow & \underline{\mathbf{CMon}}_T(\underline{\mathrm{Psh}}_T C) \\ \| & & \| \\ \underline{\mathrm{Fun}}_T\left(C^{\vee op}, \underline{\mathrm{Fun}}^{\times}_T(\underline{\mathbf{A}}^{eff}(T), \underline{\mathbf{Top}}_T)\right) & \longrightarrow & \underline{\mathrm{Fun}}_T\left(C^{\vee op}, \underline{\mathbf{CMon}}_T(\underline{\mathbf{Top}}_T)\right) \end{array},$$

where $C^{\vee op}$ is the fiberwise opposite of [9], so it is enough to show the thesis for $C = \underline{\mathbf{Top}}_T$.

We claim that sending every T-commutative monoid to its right Kan extension is the inverse of the restriction map. The first step is showing that the natural map

$$j_* M \circ j \longrightarrow M$$

is an equivalence. By applying 6.4 with $C = F = S_T$, E the subcategory of fiberwise arrows and D the category of summand inclusions (that is the egressive maps in the definition of $\underline{\mathbf{F}_*}_T$) we see that it is enough to prove that the map

$$k_*(M|_{\underline{\mathbf{F}^{in}_*}_T}) \circ k \longrightarrow M|_{\underline{\mathbf{F}^{in}_*}_T}$$

is an equivalence, where k is the inclusion of E^{op} in F^{op}. But this follows immediately from the fact that $M|_{\underline{\mathbf{F}^{in}_*}_T}$ is the right Kan extension of its restriction to T^{op}.

Hence $j_* M$ must be a product preserving functor (since the image of j contains all product diagrams in $\underline{\mathbf{A}}^{eff}(T)$. Viceversa let suppose that N is a product preserving functor from $\underline{\mathbf{A}}^{eff}(T)$ to C. Then there is a natural map

$$N \longrightarrow j_*(N \circ j)\,.$$

But since j is essentially surjective we can check that this is an equivalence after precomposing with j, which follows immediately from the previous case. □

6.6**.** With a similar proof it is possible to prove that if D is an ∞-category with finite products there is an equivalence

$$\mathrm{Fun}^{\times}(A^{eff}(T), D) \cong \mathbf{CMon}_T(D^T)\,.$$

7. T-linear functors and T-stability

Recall the definition of fiberwise linear functor and fiberwise stable cocartesian fibration from section 3.

The following definition is inspired to hypothesis (A) of [14].

7.1. **Definition.** Let C be a pointed T-∞-category with finite T-colimits and let D be a T-∞-category with finite T-limits. Then a T-functor $F : C \longrightarrow D$ is T-linear if it is fiberwise linear and T-semiadditive. A T-∞-category with all finite T-limits and T-colimits is T-stable if it is fiberwise stable and T-semiadditive.

We will denote the T-subcategory of $\underline{\mathrm{Fun}}_T(C, D)$ which on the fiber above V is spanned by $T_{/V}$-linear functors from $C \times_{T^{op}} (T_{/V})^{op}$ to $D \times_{T^{op}} (T_{/V})^{op}$ with $\underline{\mathrm{Lin}}^T(C, D)$.

7.2. **Lemma.** *Let D be a T-semiadditive T-∞-category. Then $\underline{\mathbf{Sp}}_T(D)$ is T-semiadditive (and hence T-stable) and the functor $\Omega^\infty : \underline{\mathbf{Sp}}_T(D) \longrightarrow D$ preserves T-products (and so all T-limits).*

Proof. Recall that $\underline{\mathbf{Sp}}_T(D)$ is the cocartesian fibration classified by the functor $V \mapsto \mathbf{Sp}(D_V)$ so it is clearly fiberwise semiadditive and we just need to show that for every arrow $W \longrightarrow V$ in T the pushforward functor

$$\mathbf{Sp}(D_V) \longrightarrow \mathbf{Sp}(D_W)$$

has a coinciding left and right adjoints that satisfies the Beck-Chevalley condition. But since the left and right adjoint are clearly given by postcomposition of those of $D_V \longrightarrow D_W$ the thesis follows. □

7.3. **Definition.** Let D be a T-∞-category with all finite T-limits. Then the T-∞-category of T-spectra is

$$\underline{\mathbf{Sp}}^T(D) = \underline{\mathbf{Sp}}_T(\underline{\mathbf{CMon}}_T(D)) .$$

By the previous lemma the latter category is T-stable

Note that there is a natural T-functor $\Omega^\infty : \underline{\mathbf{Sp}}^T(D) \longrightarrow D$ given by the composition

$$\underline{\mathbf{Sp}}^T(D) = \underline{\mathbf{Sp}}_T(\underline{\mathbf{CMon}}_T(D)) \xrightarrow{\Omega^\infty} \underline{\mathbf{CMon}}_T(D) \xrightarrow{I(-)_+^*} D .$$

It is immediate by the previous lemma that it preserves all T-limits.

7.4. **Theorem** (Universal property of T-spectra)**.** *Let C be a pointed T-∞-category with finite T-colimits and D be a T-∞-category with finite T-limits. Then the functor*

$$(\Omega^\infty)_* \colon \underline{\mathrm{Fun}}_T^{T-\mathrm{rex}}(C, \underline{\mathbf{Sp}}^T(D)) \longrightarrow \underline{\mathrm{Lin}}^T(C, D)$$

is an equivalence of T-∞-categories, where the source categories is the full subcategory of those functors preserving finite T-limits. In particular

$$\underline{\mathbf{Sp}}^T(D) \cong \underline{\mathrm{Lin}}_T(\underline{\mathbf{Top}_*}_T^{fin}, D) ,$$

and the functor Ω^∞ is given by evaluation at the cocartesian section $I(-)_+ : T^{op} \longrightarrow \underline{\mathbf{F}}_{*T}$.

Proof. Since the map is clearly a T-functor we just need to check that it is an equivalence fiberwise. But, remembering that finite T-colimits are generated by T-coproducts and finite fiberwise colimits, we can apply 5.11.1 and 3.7 and conclude

$$\mathrm{Fun}_T^{T-\mathrm{rex}}(C, \underline{\mathbf{Sp}}_T(\underline{\mathbf{CMon}}_T(D))) = \mathrm{Lin}_T^{\amalg}(C, \mathbf{CMon}_T(D)) = \mathrm{Lin}^T(C, D) .$$

□

7.4.1. **Corollary.** *Let D be an ∞-category with all finite limits. Then there is an equivalence*

$$\mathrm{Lin}^T(\underline{\mathbf{Top}_*}_T^{fin}, \underline{D}_T) \cong \mathrm{Fun}^{\oplus}(A^{eff}(T), \mathbf{Sp}(D)) .$$

Proof. Both of those are equivalent to the global sections of $\underline{\mathbf{Sp}}^T(\underline{D}_T)$. □

Appendix A. Comparison with orthogonal spectra

A.1. Let G be a finite group. In this appendix we will prove that our notion of G-spectra coincides with the orthogonal G-spectra developed in [22], thus reproving a theorem by Guillou and May ([17]). Fix once and for all a complete G-universe $\mathcal{U}$ (that is an isometric G-action on $\mathbb{R}^\infty$ such that every finite-dimensional representation can be isometrically embedded in $\mathbb{R}^\infty$ countably many times) and note that its restriction to a subgroup H of G is an H-universe, which we will take with indexing set given by the G-invariant subspaces. The category of orthogonal H-spectra with respect to U ([22, Df. II.2.6]) will be denoted by $\mathrm{Sp}^H_{(1)}$.

A.2. **Definition.** Let $(\mathbf{O}_G)_*$ be the category of G-orbits with a distinguished basepoint but with any possible map.[1], We will write an element of $(\mathbf{O}_G)_*$ as G/H where the distinguished basepoint is eH. It is clear that the functor $(\mathbf{O}_G)_* \longrightarrow \mathbf{O}_G$ that forgets the basepoint is an equivalence of categories. A map $G/H \longrightarrow G/K$ is the datum of $gK \in G/K$ such that $g^{-1}Hg \subseteq K$. We have a functor from $(\mathbf{O}_G)_*^{op}$ to categories sending

- A pointed orbit G/H to the category $\mathrm{Sp}^H_{(1)}$ of orthogonal H-spectra with respect to U;
- A map $G/H \longrightarrow G/K$ the composition of the functors

$$\mathrm{Sp}^K_{(1)} \longrightarrow \mathrm{Sp}^{g^{-1}Hg}_{(1)} \longrightarrow \mathrm{Sp}^H_{(1)}$$

  where the first functor is the restriction along the inclusion $g^{-1}Hg \subseteq K$ and the second functor is induced by the isomorphism $g^{-1}Hg \cong H$ given by conjugating by g^{-1}.

If we equip every category $\mathrm{Sp}^H_{(1)}$ with the family of π_*-isomorphisms ([22, Df. III.3.2]) this becomes a functor from $(\mathbf{O}_G)_*^{op}$ to the category of relative categories (since [22, Lm. V.2.2] implies that change of groups preserve π_*-isomorphisms). By precomposing with the equivalence $\mathbf{O}_G^{op} \cong (\mathbf{O}_G)_*^{op}$ and postcomposing with the localization functor from relative categories to ∞-categories we finally obtain a functor

$$\mathbf{O}_G^{op} \longrightarrow \mathbf{Cat}_\infty$$

that classifies a cocartesian fibration $\underline{\mathbf{Sp}}^G_{orth} \longrightarrow \mathbf{O}_G^{op}$. We call this cocartesian fibration the G-∞-category of orthogonal G-spectra. It comes equipped with a natural G-functor

$$\Omega^\infty : \underline{\mathbf{Sp}}^G_{orth} \longrightarrow \underline{\mathbf{Top}}_G$$

induced by the natural transformation obtained by sending every orthogonal H-spectrum to its 0-th space.

A.3. **Lemma.** *The G-∞-category $\underline{\mathbf{Sp}}^G_{orth}$ is G-stable*

Proof. Since the fibers are obtained by localizing a stable model category at the weak equivalences $\mathbf{Sp}^G_{orth}$ is fiberwise stable. So we just need to check G-semiadditivity. But after unwrapping the definitions this is equivalent to the Wirthmüller isomorphism ([19, Th. II.6.2], which holds for orthogonal G-spectra by [22, Th. III.4.16]). ∎

[1] Another way of thinking of this category is as the category of G-orbits together with an explicit isomorphism with an orbit of the form G/H. This is of course purely bookkeeping and has nothing to do with the use of basepoints when defining G-spectra.

We can now give a very simple proof of [17, Th. 0.1] along the outline in section 11 of [10].

A.4. **Theorem** (Guillou-May)**.** *The functor* $\Omega^\infty : \mathbf{Sp}^G_{orth} \longrightarrow \underline{\mathbf{Top}}_G$ *lifts to an equivalence of* G*-*∞*-categories* $\underline{\mathbf{Sp}}^G_{orth} \cong \underline{\mathbf{Sp}}^G$*.*

Proof. Since the functor $\underline{\mathbf{Sp}}^G_{orth} \longrightarrow \underline{\mathbf{Top}}_G$ preserves all finite G-limits (it has a left G-adjoint by proposition [21, Pr. 7.3.2.1]) it lifts uniquely to a functor Ξ : $\mathbf{Sp}^G_{orth} \longrightarrow \mathbf{Sp}^G$.

For every orbit V the fibers $(\mathbf{Sp}^G_{orth})_V$ and $(\mathbf{Sp}^G)_V$ are both generated by suspension spectra of orbits. Moreover Ξ sends suspension spectra of orbits to suspension spectra of orbits and is fully faithful when restricted to those subcategories by [10, Th. 10.6] and [22, Th. V.11.1], since in both settings $\mathrm{Map}(\Sigma^\infty_+ G/H, \Sigma^\infty_+ G/K)$ is just $\Omega^\infty \left(\Sigma^\infty_+ (G/H \times G/K)\right)^G$. Hence it is an equivalence by the Schwede-Shipley theorem [21, Th. 7.1.2.1]. □

From this description of G-spectra we immediately obtain a recognition principle for G-connective G-spectra

A.4.1. **Corollary.** *There is an adjuction*

$$B \dashv \Omega^\infty : \mathbf{CMon}_G(\underline{\mathbf{Top}}_G) \leftrightarrows \mathbf{Sp}^G$$

such that

- *the unit* $X \longrightarrow \Omega^\infty BX$ *is an equivalence if and only* X^H *is a group-like monoid for every subgroup* $H < G$*;*
- *the counit* $B\Omega^\infty E \longrightarrow E$ *is an equivalence if and only if* E^H *is connective for every subgroup* $H < G$*.*

Proof. After our identifications this is just the adjunction

$$\mathrm{Fun}^\times(A^{\mathit{eff}}(G), \mathbf{Top}) \cong \mathrm{Fun}^\oplus(A^{\mathit{eff}}(G), \mathbf{CMon}(\mathbf{Top})) \leftrightarrows \mathrm{Fun}^\oplus(A^{\mathit{eff}}(G), \mathbf{Sp})$$

given by postcomposition with the adjunction for ordinary spectra, and the thesis follows from the classical recognition theorem. □

Equivariant operads and normed algebras

PARAMETRIZED AND EQUIVARIANT HIGHER ALGEBRA

DENIS NARDIN AND JAY SHAH

Abstract. We develop the rudiments of a theory of parametrized ∞-operads, including parametrized generalizations of monoidal envelopes, Day convolution, operadic left Kan extensions, results on limits and colimits of algebras, and the symmetric monoidal Yoneda embedding.

Contents

1. Introduction

The goal of this paper is to lay foundations for a theory of *parametrized ∞-operads*. To explain the concept, suppose G is a finite group and let us first recall the concept of a G-symmetric monoidal ∞-category, after Hill–Hopkins [HH16], Blumberg–Hill [BH20], and Bachmann–Hoyois [BH21]. Let $\mathbf{F}_G$ be the category of finite G-sets, $\mathrm{Span}(\mathbf{F}_G)$ the $(2,1)$-category of spans of finite G-sets, and $\widehat{\mathbf{Cat}}$ the (huge) ∞-category of (large) ∞-categories.

Date: March 2, 2022.

1.0.1. **Definition.** A *G-symmetric monoidal ∞-category* is a product-preserving functor

$$\mathcal{C}^{\otimes} : \mathrm{Span}(\mathbf{F}_G) \longrightarrow \widehat{\mathbf{Cat}}.$$

For example, the ∞-category $\mathbf{Sp}^G$ of genuine G-spectra extends to a G-symmetric monoidal ∞-category $(\mathbf{Sp}^G)^{\otimes}$ whose value on G/H is equivalent to $\mathbf{Sp}^H$ and whose covariant functoriality encodes the symmetric monoidal structures on $\{\mathbf{Sp}^H\}_{H \leq G}$ as well as the *Hill–Hopkins–Ravenel norm functors* $f_{\otimes} : \mathbf{Sp}^H \longrightarrow \mathbf{Sp}^K$ associated to maps of G-orbits $f : G/H \longrightarrow G/K$ (cf. [BH21, §9]). More generally, one can substitute other base ∞-categories apart from $\mathbf{F}_G$ as needed for other applications; in particular, in the motivic context Bachmann and Hoyois work with spans over certain categories of schemes and have extensively investigated the properties of such normed symmetric monoidal ∞-categories and their algebras in [BH21].

Just as the theory of symmetric monoidal ∞-categories admits a generalization to a theory of ∞-operads, we will see that the theory of G-symmetric monoidal ∞-categories admits a corresponding sort of generalization. Roughly speaking, a *simplicial G-operad* should consist of the data of a space of multimorphisms associated to every map of finite G-sets, with a composition law then associated to every composite of maps of finite G-sets.[1] In fact, just as an ∞-operad is really the ∞-categorical counterpart of a simplicial colored operad (i.e, a simplicial multicategory), our theory of G-∞-operads will encompass both G-symmetric monoidal ∞-categories and simplicial colored G-operads via a suitably defined coherent nerve construction. Abstracting away from the equivariant situation, we will be able to make this idea work under the following hypotheses on our base ∞-category, which were first articulated in the first author's work [Nar16] on parametrized stability.

1.0.2. **Definition** ([Nar16, Def. 4.1])**.** Let $\mathcal{T}$ be a small ∞-category. We say that $\mathcal{T}$ is *orbital* if its finite coproduct completion admits all pullbacks. We say that $\mathcal{T}$ is *atomic* if it has no non-trivial retracts, so that every map with a left inverse is an equivalence.

1.0.3. **Example.** The orbit category $\mathbf{O}_G$ of a finite group is atomic orbital. Some other examples are enumerated in [Nar16, Ex. 4.2].

1.0.4. **Remark.** The condition for an ∞-category to be atomic orbital is a highly restrictive one; for example, if $\mathcal{T}$ is atomic orbital and admits a terminal object, then $\mathcal{T}$ is equivalent to the nerve of a 1-category T (Proposition 2.5.1).

At this point, the reader should examine the definition of a simplicial colored T-operad (Definition 2.5.4) to get a conceptual handle on the forthcoming definition of a $\mathcal{T}$-∞-operad.

1.1. **Summary of results.** After some preliminaries on the $\mathcal{T}$-∞-category $\underline{\mathbf{F}}_{\mathcal{T},*}$ of pointed finite $\mathcal{T}$-sets (Definition 2.1.2), we give the definition of $\mathcal{T}$-∞-operad as Definition 2.1.7 and algebras therein as Definition 2.2.1. We explicate the parametrized Segal condition (Theorem 2.3.3) and show how the definition of a $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-category recovers Definition 1.0.1 (Theorem 2.3.9). We then study parametrized generalizations of three essential constructions in the theory of ∞-operads: monoidal envelopes (Definition 2.8.4), Day convolution (Definition 3.1.6), and operadic left Kan extension (Definition 4.3.5). Finally, we study $\mathcal{T}$-(co)limits in $\mathcal{T}$-∞-categories of $\mathcal{O}$-algebras, first in the context of a general $\mathcal{T}$-∞-operad $\mathcal{O}^{\otimes}$ (Theorem 5.1.3 and Theorem 5.1.4) and then in the special case of the $\mathcal{O}^{\otimes} = \underline{\mathbf{F}}_{\mathcal{T},*}$ (Theorem 5.3.7), and we establish a $\mathcal{T}$-symmetric monoidal refinement of the universal property of $\mathcal{T}$-presheaves (Corollary 6.0.12).

1.2. **Related work.** This paper is part of a larger body of work on parametrized higher category theory and higher algebra [BDG+16a, BDG+16b, Sha21a, Sha21b, Nar16, Nar17]. In particular, all of the conventions, terminology, and notation from [Sha21b] are in force in this paper, and the reader should at least skim the introduction and §2 of [Sha21b] before reading this work. Furthermore, the definition of a $\mathcal{T}$-∞-operad was developed in joint work with Barwick, Dotto, and Glasman circa 2016 and has previously appeared in the first author's thesis [Nar17, §3.1]. On the other hand, this paper doesn't otherwise expand on [Nar17, §3]; for instance, we will not recapitulate the first author's work on tensor products of $\mathcal{T}$-presentable $\mathcal{T}$-∞-categories.

As this paper is intended to play a foundational and supporting role in the literature, we don't discuss many interesting examples or applications here. Horev [Hor19] has used these results in his development of a theory of genuine equivariant factorization homology (see also [HHK+20]), and he in particular discusses the example of the G-∞-operad $\mathbf{E}_V$ associated to a finite-dimensional real G-representation V. The second

[1] Beware that this isn't the notion of G-operad that appears in the work of Blumberg-Hill [BH15].

author and Quigley have applied these results in their study of the parametrized Tate construction [QS21a] and real cyclotomic spectra [QS21b]. Hilman has introduced similar ideas in his study of parametrized noncommutative motives and equivariant algebraic K-theory [Hil22a, Hil22b].

In a different direction, the theory of G-operads in their various guises has a long history that we don't attempt to summarize here; some recent references are [BH15, GW18, Rub21, BP21, MMO21, GMMO18]. In terms of the relationship to the N_∞-operads of Blumberg–Hill, we discuss $\mathcal{T}$-indexing systems $\mathcal{I}$ in our framework in Definition 2.4.8, the corresponding commutative $\mathcal{T}$-∞-operad $\mathrm{Com}^{\otimes}_{\mathcal{I}}$ in Definition 2.4.10, and how they identify with G-indexing systems in the sense of Blumberg–Hill when $\mathcal{T} = \mathbf{O}_G$ in Remark 2.4.12. It should be possible to adapt ideas of Hinich from [Hin15] to establish a formal comparison between the ∞-category of $\mathrm{Com}_{\mathcal{I}}$-algebras in our sense and those in the sense of [BH15], but we do not attempt to do this now.

1.3. **Acknowledgements.** We thank Clark Barwick, Emanuele Dotto, and Saul Glasman for valuable discussions in the early stages of this project. J.S. was supported by NSF grant DMS-1547292 and the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) under Germany's Excellence Strategy EXC 2044–390685587, Mathematics Münster: Dynamics–Geometry–Structure.

2. Parametrized ∞-operads

2.1. **First definitions.** We begin by introducing the basic definitions of parametrized higher algebra in parallel to Lurie's development of the foundations of ∞-operads [Lur17, §2.1]. Let $\mathcal{T}$ be an atomic orbital ∞-category, whose objects we refer to as *orbits*, and let $\mathbf{F}_{\mathcal{T}}$ be its finite coproduct completion[2], which we refer to as the ∞-category of *finite* $\mathcal{T}$*-sets*.

2.1.1. **Definition.** For every orbit $V \in \mathcal{T}$, let

$$\mathbf{F}_{\mathcal{T}/V} := (\mathbf{F}_{\mathcal{T}})^{/V} = \mathrm{Ar}(\mathbf{F}_{\mathcal{T}}) \times_{\mathbf{F}_{\mathcal{T}}} \{V\}$$

(thus fixing a preferred choice of finite coproduct completion of $\mathcal{T}^{/V}$), and let

$$\mathbf{F}_{\mathcal{T}/V,*} := (\mathbf{F}_{\mathcal{T}/V})^{\mathrm{id}_V/} = (\mathbf{F}_{\mathcal{T}})^{V//V}$$

be the ∞-category of *finite pointed* $\mathcal{T}^{/V}$*-sets*.

Using that $\mathcal{T}$ is orbital, we could then define the $\mathcal{T}$-∞*-category of finite* $\mathcal{T}$*-sets* $\underline{\mathbf{F}}_{\mathcal{T}}$ as the full $\mathcal{T}$-subcategory of $\underline{\mathbf{Spc}}_{\mathcal{T}}$ spanned by the finite $\mathcal{T}^{/V}$-sets in each fiber $(\underline{\mathbf{Spc}}_{\mathcal{T}})_V$ over an orbit V, so that as a cocartesian fibration, $\underline{\mathbf{F}}_{\mathcal{T}}$ is classified by the assignment $V \rightsquigarrow (\mathbf{F}_{\mathcal{T}})^{/V}$ with functoriality that given by pullback. Similarly, we could define a pointed variant $\underline{\mathbf{F}}_{\mathcal{T},*}$ as the full $\mathcal{T}$-subcategory of $\underline{\mathbf{Spc}}_{\mathcal{T},*}$ classified by the assignment $V \rightsquigarrow (\mathbf{F}_{\mathcal{T}})^{V//V}$.

However, although conceptually transparent, these definitions of $\underline{\mathbf{F}}_{\mathcal{T}}$ and $\underline{\mathbf{F}}_{\mathcal{T},*}$ are ill-suited to writing down arbitrary morphisms that may interpolate between different fibers. Instead, we will follow the first author's work in [Nar16, §4] and instead define $\underline{\mathbf{F}}_{\mathcal{T}}$ and $\underline{\mathbf{F}}_{\mathcal{T},*}$ as certain ∞-categories of spans, along the lines of the construction of the dual cocartesian fibration in [BGN18] as well as the span description of finite pointed sets in terms of finite sets and partially defined maps (cf. [Nar16, 4.11]).

2.1.2. **Definition.** Let

$$\underline{\mathbf{F}}^{\mathrm{v}}_{\mathcal{T}} := \mathrm{Ar}(\mathbf{F}_{\mathcal{T}}) \times_{\mathbf{F}_{\mathcal{T}}} \mathcal{T},$$

so that the functor $\mathrm{ev}_1 : \underline{\mathbf{F}}^{\mathrm{v}}_{\mathcal{T}} \longrightarrow \mathcal{T}$ given by evaluation at the target is a cartesian fibration classified by $V \rightsquigarrow (\mathbf{F}_{\mathcal{T}})^{/V}$. Labeling an arbitrary morphism $[\phi : f \longrightarrow g]$ of $\underline{\mathbf{F}}^{\mathrm{v}}_{\mathcal{T}}$ as

$$\begin{array}{ccc} U & \xrightarrow{h} & X \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle g} \\ V & \xrightarrow{k} & Y, \end{array}$$

we define wide subcategories

$$(\underline{\mathbf{F}}^{\mathrm{v}}_{\mathcal{T}})^{tdeg},\ (\underline{\mathbf{F}}^{\mathrm{v}}_{\mathcal{T}})^{si},\ (\underline{\mathbf{F}}^{\mathrm{v}}_{\mathcal{T}})^{cart} \subset \underline{\mathbf{F}}^{\mathrm{v}}_{\mathcal{T}}$$

[2] Explicitly, we could take $\mathbf{F}_{\mathcal{T}} \subset \mathbf{P}(\mathcal{T})$ to be the full subcategory spanned by finite coproducts of representables. However, any equivalent choice will suffice.

as containing those morphisms ϕ such that k is degenerate, $U \longrightarrow X \times_Y V$ is a summand inclusion, and $U \longrightarrow X \times_Y V$ is an equivalence, respectively.[3] Then the triples

$$(\underline{\mathbf{F}}^{\vee}_{\mathcal{T}}; (\underline{\mathbf{F}}^{\vee}_{\mathcal{T}})^{cart}, (\underline{\mathbf{F}}^{\vee}_{\mathcal{T}})^{tdeg}) \quad \text{and} \quad (\underline{\mathbf{F}}^{\vee}_{\mathcal{T}}; (\underline{\mathbf{F}}^{\vee}_{\mathcal{T}})^{si}, (\underline{\mathbf{F}}^{\vee}_{\mathcal{T}})^{tdeg})$$

are adequate in the sense of [Bar17, 5.2].[4] Consequently, we may form the associated span ∞-categories[5]

$$\underline{\mathbf{F}}_{\mathcal{T}} \coloneqq \mathrm{Span}(\underline{\mathbf{F}}^{\vee}_{\mathcal{T}}; (\underline{\mathbf{F}}^{\vee}_{\mathcal{T}})^{cart}, (\underline{\mathbf{F}}^{\vee}_{\mathcal{T}})^{tdeg}) \quad \text{and} \quad \underline{\mathbf{F}}_{\mathcal{T},*} \coloneqq \mathrm{Span}(\underline{\mathbf{F}}^{\vee}_{\mathcal{T}}; (\underline{\mathbf{F}}^{\vee}_{\mathcal{T}})^{si}, (\underline{\mathbf{F}}^{\vee}_{\mathcal{T}})^{tdeg}).$$

We regard $\underline{\mathbf{F}}_{\mathcal{T}}$ and $\underline{\mathbf{F}}_{\mathcal{T},*}$ as $\mathcal{T}$-∞-categories via the structure map ev_1 given by evaluation at the target, so that a morphism ψ (for either ∞-category)

$$\begin{array}{ccccc} U & \longleftarrow & Z & \xrightarrow{m} & X \\ \downarrow & & \downarrow & & \downarrow \\ V & \longleftarrow & Y & \xrightarrow{=} & Y. \end{array}$$

is ev_1-cocartesian if and only if $m : Z \longrightarrow X$ is an equivalence and $Z \longrightarrow U \times_V Y$ is an equivalence (cf. [Nar16, Lem. 4.9 and Def. 4.12]). The canonical inclusion $\underline{\mathbf{F}}_{\mathcal{T}} \subset \underline{\mathbf{F}}_{\mathcal{T},*}$ of span ∞-categories is thus the inclusion of a $\mathcal{T}$-subcategory. We also have an 'identity' cocartesian section $I : \mathcal{T}^{\mathrm{op}} \longrightarrow \underline{\mathbf{F}}_{\mathcal{T}}$ that sends V to $[V = V]$.

2.1.3. **Definition.** In the notation of Definition 2.1.2, we declare a morphism ψ in $\underline{\mathbf{F}}_{\mathcal{T},*}$ to be *inert* if $m : Z \longrightarrow X$ is an equivalence and *active* if $Z \longrightarrow U \times_V Y$ is an equivalence. Note that a morphism ψ in $\underline{\mathbf{F}}_{\mathcal{T},*}$ is both inert and active if and only if ψ is ev_1-cocartesian.

2.1.4. **Remark.** Note that $\underline{\mathbf{F}}_{\mathcal{T}}$ is by definition the dual cocartesian fibration to $\underline{\mathbf{F}}^{\vee}_{\mathcal{T}}$ in the sense of [BGN18, Def. 3.4]. As such, for any orbit V we have an equivalence

$$(\underline{\mathbf{F}}^{\vee}_{\mathcal{T}})_V = \mathbf{F}_{\mathcal{T}/V} \xrightarrow{\simeq} \mathrm{Span}(\mathbf{F}_{\mathcal{T}/V}; (\mathbf{F}_{\mathcal{T}/V})^{\simeq}, \mathbf{F}_{\mathcal{T}/V}) = (\underline{\mathbf{F}}_{\mathcal{T}})_V$$

implemented by inclusion.

We next describe $\underline{\mathbf{F}}_{\mathcal{T},*}$. Let $\mathbf{F}^{si}_{\mathcal{T}}$ denote the wide subcategory on the summand inclusions in $\mathbf{F}_{\mathcal{T}}$, so $(\underline{\mathbf{F}}^{\vee}_{\mathcal{T}})^{si}_V = \mathbf{F}^{si}_{\mathcal{T}/V}$. As was noted in [Nar16, Lem. 4.14], for any orbit V we have an equivalence

$$(\underline{\mathbf{F}}_{\mathcal{T},*})_V = \mathrm{Span}(\mathbf{F}_{\mathcal{T}/V}; \mathbf{F}^{si}_{\mathcal{T}/V}, \mathbf{F}_{\mathcal{T}/V}) \xrightarrow{\simeq} \mathbf{F}_{\mathcal{T}/V,*},$$

under which an object $[U \xrightarrow{f} V]$ is sent to $[U \sqcup V \xrightarrow{f \sqcup \mathrm{id}} V]$ pointed at V, and a span

$$U \xleftarrow{\alpha} W \xrightarrow{\beta} U',$$

with α given by the summand inclusion $W \subset W \sqcup W' \simeq U$, is sent to the pointed map

$$U \sqcup V \xrightarrow{\gamma} U' \sqcup V$$

with $\gamma|_W = \beta$ and $\gamma|_{W'} = \mathrm{const}_V$. Consequently, we will often refer to an object $f = [U \longrightarrow V]$ of $\underline{\mathbf{F}}_{\mathcal{T},*}$ as $f_+ = [U_+ \longrightarrow V]$ to emphasize the implicit presence of the basepoint. We will also denote the canonical inclusion $\underline{\mathbf{F}}_{\mathcal{T}} \subset \underline{\mathbf{F}}_{\mathcal{T},*}$ of span ∞-categories by

$$(-)_+ : \underline{\mathbf{F}}_{\mathcal{T}} \hookrightarrow \underline{\mathbf{F}}_{\mathcal{T},*}$$

and refer to this as the *pointing* T-functor. By [Nar16, Lem. 4.14], $(-)_+$ has a 'forgetful' right T-adjoint which sends $[U_+ \longrightarrow V]$ to $[U \sqcup V \longrightarrow V]$. Note also that a morphism ψ in $\underline{\mathbf{F}}_{\mathcal{T},*}$ is active if and only if it is in the image of $(-)_+$.

2.1.5. **Remark.** For an orbit $V \in \mathcal{T}$, we obtain from Definition 2.1.3 a definition for inert and active edges in $(\underline{\mathbf{F}}_{\mathcal{T},*})_V$ by restriction to the fiber. Under the equivalence $(\underline{\mathbf{F}}_{\mathcal{T},*})_V \simeq \mathbf{F}_{\mathcal{T}/V,*}$ of Remark 2.1.4, a pointed map $f : U \sqcup V \longrightarrow U' \sqcup V$ is then inert if and only if its pullback along $U' \subset U' \sqcup V$ is an equivalence, and is active if and only if $f \simeq g_+$ for some $g : U \longrightarrow U'$ in $\mathbf{F}_{\mathcal{T}/V}$.

[3] Note that the "target degenerate" morphisms are a subclass of ev_1-cocartesian edges (for which more generally the map k is an equivalence) and the "cartesian" morphisms are exactly the ev_1-cartesian edges.

[4] Note that we have swapped the order of the wide subcategories from that of [Bar17], so that the first subcategory will indicate the backward facing arrows and the second will indicate the forward facing arrows when forming the span ∞-category.

[5] In [Bar17] and [Nar16], the term "effective Burnside ∞-category" A^{eff} is used as a synonym for "span ∞-category".

2.1.6. **Definition.** Suppose $f_+ = [U_+ \longrightarrow V]$ is an object of $\underline{\mathbf{F}}_{\mathcal{T},*}$. Let $\mathrm{Orbit}(U)$ be the set of orbits of U, so that we have an equivalence

$$U \simeq \coprod_{W \in \mathrm{Orbit}(U)} W$$

in $\mathbf{F}_{\mathcal{T}}$ with each W an object in $\mathcal{T}$. Given $W \in \mathrm{Orbit}(U)$, the *characteristic morphism*

$$\chi_{[W \subset U]} : f_+ \longrightarrow I(W)_+$$

is defined to be

$$\begin{array}{ccccc} U & \longleftarrow & W & \xrightarrow{=} & W \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle =} & & \downarrow{\scriptstyle =} \\ V & \longleftarrow & W & \xrightarrow{=} & W. \end{array}$$

Here we make essential use of our assumption that $\mathcal{T}$ is atomic to ensure that $W \longrightarrow U \times_V W$ is a summand inclusion. Clearly, $\chi_{[W \subset U]}$ is inert.

2.1.7. **Definition.** A $\mathcal{T}$-∞-*operad* is a pair $(\mathcal{C}^{\otimes}, p)$ consisting of a $\mathcal{T}$-∞-category $\mathcal{C}^{\otimes}$ along with a $\mathcal{T}$-functor $p : \mathcal{C}^{\otimes} \longrightarrow \underline{\mathbf{F}}_{\mathcal{T},*}$, which is a categorical fibration and satisfies the following additional conditions:

(1) For every inert morphism $\psi : f_+ \longrightarrow g_+$ of $\underline{\mathbf{F}}_{\mathcal{T},*}$ and every object $x \in \mathcal{C}^{\otimes}_{f_+}$, there is a p-cocartesian edge $x \longrightarrow y$ in $\mathcal{C}^{\otimes}$ covering ψ.

(2) For any object $f_+ = [U_+ \longrightarrow V]$ of $\underline{\mathbf{F}}_{\mathcal{T},*}$, the p-cocartesian edges lying over the characteristic morphisms

$$\left\{ \chi_{[W \subset U]} : f_+ \longrightarrow I(W)_+ \ \middle|\ W \in \mathrm{Orbit}(U) \right\}$$

together induce an equivalence

$$\prod_{W \in \mathrm{Orbit}(U)} (\chi_{[W \subset U]})_! : \mathcal{C}^{\otimes}_{f_+} \xrightarrow{\sim} \prod_{W \in \mathrm{Orbit}(U)} \mathcal{C}^{\otimes}_{I(W)_+}.$$

(3) For any morphism

$$\psi : f_+ = [U_+ \longrightarrow V] \longrightarrow g_+ = \left[U'_+ \longrightarrow V'\right]$$

of $\underline{\mathbf{F}}_{\mathcal{T},*}$, objects $x \in \mathcal{C}^{\otimes}_{f_+}$ and $y \in \mathcal{C}^{\otimes}_{g_+}$, and any choice of p-cocartesian edges

$$\{y \longrightarrow y_W \ \mid\ W \in \mathrm{Orbit}(U')\}$$

lying over the characteristic morphisms

$$\left\{ \chi_{[W \subset U']} : g_+ \longrightarrow I(W)_+ \ \middle|\ W \in \mathrm{Orbit}(U') \right\},$$

the induced map

$$\mathrm{Map}^{\psi}_{\mathcal{C}^{\otimes}}(x, y) \xrightarrow{\sim} \prod_{W \in \mathrm{Orbit}(U')} \mathrm{Map}^{\chi_{[W \subset U']} \circ \psi}_{\mathcal{C}^{\otimes}}(x, y_W)$$

is an equivalence.

We will typically omit the structure map p and simply refer to $\mathcal{C}^{\otimes}$ as a $\mathcal{T}$-∞-operad. Given a $\mathcal{T}$-∞-operad $\mathcal{C}^{\otimes}$, its *underlying* $\mathcal{T}$-∞-*category* is the fiber product

$$\mathcal{C} := \mathcal{T}^{\mathrm{op}} \times_{I(-)_+, \underline{\mathbf{F}}_{\mathcal{T},*}} \mathcal{C}^{\otimes}.$$

2.1.8. **Definition.** Suppose $(\mathcal{C}^{\otimes}, p)$ is a $\mathcal{T}$-∞-operad. Then an edge of $\mathcal{C}^{\otimes}$ is *inert* if it is p-cocartesian over an inert edge of $\underline{\mathbf{F}}_{\mathcal{T},*}$, and is *active* if it factors as a p-cocartesian edge followed by an edge lying over a fiberwise active edge in $\underline{\mathbf{F}}_{\mathcal{T},*}$. We let $\mathcal{C}^{\otimes}_{ne}$ be the wide $\mathcal{T}$-subcategory of $\mathcal{C}^{\otimes}$ on the inert edges, and $\mathcal{C}^{\otimes}_{act}$ the wide $\mathcal{T}$-subcategory of $\mathcal{C}^{\otimes}$ on the active edges.

2.1.9. **Remark.** Let $\mathcal{C}^{\otimes}$ be a $\mathcal{T}$-∞-operad and $U \in \mathbf{F}_{\mathcal{T}}$. Note that for *any* orbit V and morphism $f : U \longrightarrow V$, we have an equivalence

$$\mathcal{C}^{\otimes}_{f_+} \simeq \mathcal{C}_U = \prod_{W \in \mathrm{Orbit}(U)} \mathcal{C}_W.$$

We will often write objects $x \in \mathcal{C}^{\otimes}_{f_+}$ as tuples (x_W).

2.1.10. **Remark** (Simplified condition on mapping spaces)**.** In Definition 2.1.7, in view of the inert-fiberwise active factorization system on a $\mathcal{T}$-∞-operad (Example 2.8.1) we may replace (3) by the following apparently weaker condition:

(3') Let $\alpha : [U \xrightarrow{f} V] \longrightarrow [U' \xrightarrow{g} V]$ be a morphism in $\mathbf{F}_{\mathcal{T}/V}$, which defines an active edge α_+ in $(\underline{\mathbf{F}}_{\mathcal{T},*})_V$. Let $x \in \mathcal{C}^{\otimes}_{f_+}$, $y \in \mathcal{C}^{\otimes}_{g_+}$ be objects, and for each $W \in \mathrm{Orbit}(U')$ let $y \longrightarrow y_W$ be a p-cocartesian edge lifting the characteristic morphism $\chi_{[W \subset U']}$. For every $W \in \mathrm{Orbit}(U')$ we have a commutative square

$$\begin{array}{ccc} [U_+ \longrightarrow V] & \xrightarrow{\alpha_+} & [U'_+ \longrightarrow V] \\ \big\downarrow{\scriptstyle \rho_W} & & \big\downarrow{\scriptstyle \chi_{[W \subset U']}} \\ [(U \times_{U'} W)_+ \longrightarrow W] & \xrightarrow{(\alpha_W)_+} & [W_+ \longrightarrow W] \end{array}$$

where ρ_W is the inert edge corresponding to the summand inclusion $U \times_{U'} W \longrightarrow U \times_V W$ and $\alpha_W : U \times_{U'} W \longrightarrow W$ is the pullback of $\alpha : U \longrightarrow U'$ along $W \subset U'$. (Note that the lower composition is the inert-fiberwise active factorization of the upper composition $\chi_{[W \subset U']} \circ \alpha_+$.) Let

$$\{x \longrightarrow x_W \mid W \in \mathrm{Orbit}(U')\}$$

be any choice of p-cocartesian edges lying over the morphisms ρ_W. Then the induced map

$$\mathrm{Map}^{\alpha_+}_{\mathcal{C}^{\otimes}}(x, y) \xrightarrow{\simeq} \prod_{W \in \mathrm{Orbit}(U')} \mathrm{Map}^{(\alpha_W)_+}_{\mathcal{C}^{\otimes}}(x_W, y_W) \tag{2.1.1}$$

is an equivalence.

2.1.11. **Remark** (Spaces of multimorphisms and operadic composition)**.** Suppose $\mathcal{C}^{\otimes}$ is a $\mathcal{T}$-∞-operad, $\alpha : U \longrightarrow U'$ is a morphism in $\mathbf{F}_{\mathcal{T}}$, and $x \in \mathcal{C}_U$, $y \in \mathcal{C}_{U'}$ are tuples of objects in $\mathcal{C}$. For every $W \in \mathrm{Orbit}(U')$, let

$$\alpha_W : U_W = U \times_{U'} W \longrightarrow W$$

be the pullback of α along the summand inclusion $W \subset U'$. Consider the component y_W of y as an object in $\mathcal{C}^{\otimes}_{I(W)_+}$ and the sub-tuple $x_W \in \mathcal{C}_{U_W}$ of x as an object in $\mathcal{C}^{\otimes}_{(\alpha_W)_+}$. Let

$$\mathrm{Mul}^{\alpha}_{\mathcal{C}}(x, y) := \prod_{W \in \mathrm{Orbit}(U')} \mathrm{Map}^{(\alpha_W)_+}_{\mathcal{C}^{\otimes}}(x_W, y_W)$$

be the space of $(\alpha; x, y)$-*multimorphisms* encoded by $\mathcal{C}^{\otimes}$. Then for any choice of map $U' \longrightarrow V$ in $\mathbf{F}_{\mathcal{T}}$ down to an orbit V, we have the canonical equivalence

$$\mathrm{Map}^{\alpha_+}_{\mathcal{C}^{\otimes}}(x, y) \simeq \mathrm{Mul}^{\alpha}_{\mathcal{C}}(x, y)$$

of (2.1.1) (compare Remark 2.1.9).

These spaces of multimorphisms are interrelated by the structure of $\mathcal{C}^{\otimes}$. For instance, for every composite morphism $U_0 \xrightarrow{\alpha} U_1 \xrightarrow{\beta} U_2$ in $\mathbf{F}_{\mathcal{T}}$ and $x_i \in \mathcal{C}_{U_i}$, $i \in \{0, 1, 2\}$, any choice of map $\rho : U_2 \longrightarrow V$ to an orbit V yields a map

$$\circ : \mathrm{Mul}^{\alpha}_{\mathcal{C}}(x_0, x_1) \times \mathrm{Mul}^{\beta}_{\mathcal{C}}(x_1, x_2) \longrightarrow \mathrm{Mul}^{\beta \circ \alpha}_{\mathcal{C}}(x_0, x_2)$$

defined by the composition in $\mathcal{C}^{\otimes}$, and one may check that this map is independent of the choice of ρ. Likewise, for every composition of pullback squares in $\mathbf{F}_{\mathcal{T}}$

$$\begin{array}{ccccc} X & \xrightarrow{f^*\alpha} & X' & \longrightarrow & W \\ \big\downarrow & & \big\downarrow & & \big\downarrow{\scriptstyle f} \\ U & \xrightarrow{\alpha} & U' & \longrightarrow & V \end{array}$$

with V, W orbits, and objects $x \in \mathcal{C}_U$, $y \in \mathcal{C}_{U'}$, one has a base-change map

$$f^* : \mathrm{Mul}^{\alpha}_{\mathcal{C}}(x, y) \longrightarrow \mathrm{Mul}^{f^*\alpha}_{\mathcal{C}}(f^*x, f^*y)$$

induced by the cocartesian pushforward in $\mathcal{C}^{\otimes}$ along f in $\mathcal{T}^{\mathrm{op}}$. Note that these maps extend the functoriality on the underlying $\mathcal{T}$-∞-category $\mathcal{C}$.

Altogether, these maps satisfy homotopy coherent unitality, associativity, and base-change compatibility constraints as encapsulated by $\mathcal{C}^{\otimes}$.

2.2. **Morphisms of operads.** We next introduce morphisms of $\mathcal{T}$-∞-operads and algebras over $\mathcal{T}$-∞-operads.

2.2.1. **Definition.** Suppose $\mathcal{C}^{\otimes}$ and $\mathcal{D}^{\otimes}$ are two $\mathcal{T}$-∞-operads. A *morphism of* $\mathcal{T}$-∞-*operads* is a $\mathcal{T}$-functor

$$A : \mathcal{C}^{\otimes} \longrightarrow \mathcal{D}^{\otimes}$$

over $\underline{\mathbf{F}}_{\mathcal{T},*}$ that carries inert morphisms to inert morphisms. Conceptually, A is a $\mathcal{C}$-*algebra valued in* $\mathcal{D}$.

If A is moreover a categorical fibration, then we call A a *fibration of* $\mathcal{T}$-∞-*operads*. Given fibrations of $\mathcal{T}$-∞-operads $p : \mathcal{C}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ and $q : \mathcal{D}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$, we let

$$\mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{D})$$

denote the full subcategory of $\mathrm{Fun}_{/\mathcal{O}^{\otimes}}(\mathcal{C}^{\otimes}, \mathcal{D}^{\otimes})$ spanned by the morphisms of $\mathcal{T}$-∞-operads, and

$$\underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{D})$$

the corresponding full $\mathcal{T}$-subcategory of the $\mathcal{T}$-∞-category $\underline{\mathrm{Fun}}_{/\mathcal{O}^{\otimes},\mathcal{T}}(\mathcal{C}^{\otimes}, \mathcal{D}^{\otimes})$ [Sha21b, Notn. 4.7].[6]

If p is the identity on $\mathcal{O}^{\otimes}$, then we will also denote $\mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{D})$ as $\mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{D})$. If $\mathcal{O}^{\otimes} = \underline{\mathbf{F}}_{\mathcal{T},*}$, then we will also denote $\mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{D})$ as $\mathbf{Alg}_{\mathcal{T}}(\mathcal{C}, \mathcal{D})$. Combining these two cases, if $\mathcal{C}^{\otimes} = \mathcal{O}^{\otimes} = \underline{\mathbf{F}}_{\mathcal{T},*}$, then we will also denote $\mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{D})$ as $\mathbf{CAlg}_{\mathcal{T}}(\mathcal{D})$, the ∞-category of $\mathcal{T}$-*commutative algebras* in $\mathcal{D}$.

2.2.2. **Warning.** In the case $\mathcal{T} = *$, our notation for ∞-categories of algebras conflicts with that of Lurie in [Lur17, Def. 2.1.3.1].

2.2.3. **Definition.** Suppose $p : \mathcal{C}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ is a fibration of $\mathcal{T}$-∞-operads in which p is moreover a cocartesian fibration. In this case, we call $\mathcal{C}^{\otimes}$ a $\mathcal{O}$-*monoidal* $\mathcal{T}$-∞-category. If $\mathcal{O}^{\otimes} = \underline{\mathbf{F}}_{\mathcal{T},*}$, we also call $\mathcal{C}^{\otimes}$ a $\mathcal{T}$-*symmetric monoidal* $\mathcal{T}$-∞-category.[7] We also refer to $\mathcal{C}$ as $\mathcal{O}$-monoidal if the additional structure $(\mathcal{C}^{\otimes}, p)$ is understood from context.

2.2.4. **Notation.** Let $\mathcal{C}^{\otimes}$ be an $\mathcal{O}$-monoidal $\mathcal{T}$-∞-category. For an active morphism $f : x \longrightarrow y$ in $\mathcal{O}^{\otimes}$, we typically denote the cocartesian pushforward functor associated to f by $f_{\otimes} : \mathcal{C}^{\otimes}_x \longrightarrow \mathcal{C}^{\otimes}_y$ and refer to it as the *norm functor* for f. If $\mathcal{O}^{\otimes} = \underline{\mathbf{F}}_{\mathcal{T},*}$, then for any morphism $f : U \longrightarrow V$ of finite $\mathcal{T}$-sets with V an orbit, we have a norm functor $f_{\otimes} : \mathcal{C}_U \longrightarrow \mathcal{C}_V$ associated to $f_+ : [U_+ \to V] \longrightarrow [V_+ \to V]$. More generally, if V is a finite $\mathcal{T}$-set with orbit decomposition $\coprod_{i=1}^{n} V_i$ so that $f = \coprod_{i=1}^{n}(f_i : U_i \longrightarrow V_i)$, then we let $f_{\otimes}$ be the product of the functors $\{(f_i)_{\otimes}\}_{i=1}^{n}$. (We will also describe in Section 2.7 how to dispense with the orbit restriction in the formalism by passing to 'big' $\mathcal{T}$-∞-operads.)

2.2.5. **Definition.** Given two $\mathcal{O}$-monoidal $\mathcal{T}$-∞-categories $p, q : \mathcal{C}^{\otimes}, \mathcal{D}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$, a $\mathcal{T}$-functor $F : \mathcal{C}^{\otimes} \longrightarrow \mathcal{D}^{\otimes}$ is *lax* $\mathcal{O}$-*monoidal* if it is a morphism of $\mathcal{T}$-∞-operads, and is *(strict)* $\mathcal{O}$-*monoidal* if it carries p-cocartesian edges to q-cocartesian edges. We let

$$\mathrm{Fun}^{\otimes}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{D})$$

denote the subcategory of $\mathrm{Fun}_{/\mathcal{O}^{\otimes}}(\mathcal{C}^{\otimes}, \mathcal{D}^{\otimes})$ spanned by the $\mathcal{O}$-monoidal $\mathcal{T}$-functors, and

$$\underline{\mathrm{Fun}}^{\otimes}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{D})$$

the corresponding $\mathcal{T}$-subcategory of $\underline{\mathrm{Fun}}_{/\mathcal{O}^{\otimes},\mathcal{T}}(\mathcal{C}^{\otimes}, \mathcal{D}^{\otimes})$. We will also drop $\mathcal{O}$ from the notation if $\mathcal{O}^{\otimes} = \underline{\mathbf{F}}_{\mathcal{T},*}$ and speak of lax and strict $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-functors.

In the situation of a cocartesian fibration $p : \mathcal{C}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ over a $\mathcal{T}$-∞-operad $\mathcal{O}^{\otimes}$, we have the following simplification of the conditions for $\mathcal{C}^{\otimes}$ to be a $\mathcal{T}$-∞-operad (and hence $\mathcal{O}$-monoidal).

2.2.6. **Proposition.** *Let* $(\mathcal{O}^{\otimes}, q)$ *be a* $\mathcal{T}$-∞-*operad and let* $p : \mathcal{C}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ *be a cocartesian fibration of* $\mathcal{T}$-∞-*categories. Then* $(\mathcal{C}^{\otimes}, q \circ p)$ *is a* $\mathcal{T}$-∞-*operad if and only if for every* $f_+ = [U_+ \longrightarrow V] \in \underline{\mathbf{F}}_{\mathcal{T},*}$ *and* $x \in \mathcal{O}^{\otimes}_{f_+}$, *the inert edges* $\{x \longrightarrow x_W \mid W \in \mathrm{Orbit}(U)\}$ *in* $\mathcal{O}^{\otimes}$ *together induce an equivalence*

$$\mathcal{C}^{\otimes}_x \xrightarrow{\sim} \prod_{W \in \mathrm{Orbit}(U)} \mathcal{C}^{\otimes}_{x_W}.$$

[6] For this definition to be sensible, note that for any map $V \longrightarrow W$ in $\mathcal{T}$, the pullback of a $\mathcal{T}^{/W}$-∞-operad along the induced functor $(\mathcal{T}^{/V})^{\mathrm{op}} \longrightarrow (\mathcal{T}^{/W})^{\mathrm{op}}$ is again a $\mathcal{T}^{/V}$-∞-operad, and likewise for morphisms of $\mathcal{T}^{/W}$-∞-operads.

[7] We may also write "$\mathcal{T}$-symmetric monoidal ∞-category" for this notion since there is no potential for ambiguity.

Proof. The proof is exactly analogous to that of [Lur17, Prop. 2.1.2.12], so we will omit it. □

Lastly, we state the evident notions of $\mathcal{T}$-suboperad and $\mathcal{O}$-monoidal $\mathcal{T}$-subcategory.

2.2.7. **Definition.** Let $(\mathcal{C}^{\otimes}, p)$ be a $\mathcal{T}$-∞-operad and let $\mathcal{D}^{\otimes}$ be a $\mathcal{T}$-subcategory of $\mathcal{C}^{\otimes}$ with inclusion $\mathcal{T}$-functor i. We say that $\mathcal{D}^{\otimes}$ is a $\mathcal{T}$-*suboperad* of $\mathcal{C}^{\otimes}$ if $p \circ i$ exhibits $\mathcal{D}^{\otimes}$ as a $\mathcal{T}$-∞-operad and i is a morphism of $\mathcal{T}$-∞-operads. If $\mathcal{C}^{\otimes}$ is moreover an $\mathcal{O}$-monoidal $\mathcal{T}$-∞-category via $q : \mathcal{C}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$, then $\mathcal{D}^{\otimes}$ is a $\mathcal{O}$-*monoidal* $\mathcal{T}$-*subcategory* of $\mathcal{C}^{\otimes}$ if $\mathcal{D}^{\otimes} \subset \mathcal{C}^{\otimes}$ is stable under q-cocartesian edges, so that $q \circ i$ exhibits $\mathcal{D}^{\otimes}$ as an $\mathcal{O}$-monoidal $\mathcal{T}$-∞-category and i is an $\mathcal{O}$-monoidal functor.

2.3. **Parametrized Segal condition.** We next want to interpret condition (2) of Definition 2.1.7 as an equivalence of $\mathcal{T}^{/V}$-∞-categories (i.e., a $\mathcal{T}$-*Segal condition*). First, we extend our notation for the $\mathcal{T}$-fibers of a $\mathcal{T}$-functor.

2.3.1. **Notation.** Let $F : \mathcal{X} \longrightarrow \mathcal{C}$ be a $\mathcal{T}$-functor and let $\sigma : \Delta^n \longrightarrow \mathcal{C}$ be a n-simplex of $\mathcal{C}$. Define the $\mathcal{T}$-*fiber of* $\mathcal{X}$ *over* σ to be

$$\mathcal{X}_{\underline{\sigma}} := \Delta^n \times_{\sigma, \mathcal{C}, \mathrm{ev}_0} \mathrm{Ar}^{cocart}(\mathcal{C}) \times_{\mathrm{ev}_1, \mathcal{C}, F} \mathcal{X}.$$

2.3.2. **Construction.** For any $\mathcal{T}$-∞-category $\mathcal{X}$ and edge $f : x \longrightarrow y$ in $\mathcal{X}$, we can construct a $\mathcal{T}$-functor

$$\phi : \Delta^1 \times \underline{y} = \Delta^1 \times (\Delta^0 \times_{y, \mathcal{X}, \mathrm{ev}_0} \mathrm{Ar}^{cocart}(\mathcal{X})) \longrightarrow \Delta^1 \times_{f, \mathcal{X}, \mathrm{ev}_0} \mathrm{Ar}^{cocart}(\mathcal{X})$$

which fits into the commutative diagram

$$\begin{array}{ccc}
\{0\} \times \underline{y} & \xrightarrow{\quad f^* \quad} & \underline{x} \\
\downarrow & & \downarrow \\
\Delta^1 \times \underline{y} & \xrightarrow{\phi} & \Delta^1 \times_{f, \mathcal{X}, \mathrm{ev}_0} \mathrm{Ar}^{cocart}(\mathcal{X}) \\
\uparrow & & \uparrow \\
\{1\} \times \underline{y} & \xrightarrow{\quad = \quad} & \underline{y},
\end{array}$$

where $f^* : \underline{y} \longrightarrow \underline{x}$ is the $\mathcal{T}$-functor defined in [Sha21a, Rem. 12.11], which sends a cocartesian edge $[e : y \to z]$ to the cocartesian edge $[f^*(e) : x \to z']$ given by the factorization of $[e \circ f]$ as the composite of $f^*(e)$ and a fiberwise edge $\phi(e)_1$.

Explicitly, let $h : \Delta^1 \times \Delta^1 \longrightarrow \mathcal{X}$ be given by

$$\begin{array}{ccc}
x & \xrightarrow{f} & y \\
{\scriptstyle f}\downarrow & & \downarrow{\scriptstyle =} \\
y & \xrightarrow{=} & y
\end{array}$$

and let

$$\mathcal{M} = \Delta^1 \times_{h, \widetilde{\mathrm{Fun}}_{\Delta^1}(\Delta^1 \times \Delta^1, \mathcal{X} \times \Delta^1), \mathrm{ev}_0} \widetilde{\mathrm{Fun}}_{\Delta^1}(\Delta^1 \times \Delta^1, \mathrm{Ar}^{cocart}(\mathcal{X}) \times \Delta^1) \times_{\mathrm{ev}_1, \widetilde{\mathrm{Fun}}_{\Delta^1}(\Delta^1 \times \Delta^1, \mathcal{T}^{\mathrm{op}} \times \Delta^1), I} (\mathcal{T}^{\mathrm{op}} \times \Delta^1),$$

where I denotes the identity section, so that $\mathcal{M} \longrightarrow \Delta^1 \times \mathcal{T}^{\mathrm{op}}$ is a $\mathcal{T}$-correspondence with

$$\mathcal{M}_0 = \{0\} \times_{f, \mathrm{Ar}(\mathcal{X}), \mathrm{ev}_0} \mathrm{Ar}(\mathrm{Ar}^{cocart}(\mathcal{X})) \times_{\mathrm{ev}_1, \mathrm{Ar}(\mathcal{T}^{\mathrm{op}}), I} \mathcal{T}^{\mathrm{op}},$$
$$\mathcal{M}_1 = \{0\} \times_{\mathrm{id}_y, \mathrm{Ar}(\mathcal{X}), \mathrm{ev}_0} \mathrm{Ar}(\mathrm{Ar}^{cocart}(\mathcal{X})) \times_{\mathrm{ev}_1, \mathrm{Ar}(\mathcal{T}^{\mathrm{op}}), I} \mathcal{T}^{\mathrm{op}}.$$

We have a zig-zag of $\mathcal{T}$-functors over $\Delta^1 \times \mathcal{T}^{\mathrm{op}}$

$$\underline{y} \times \Delta^1 \overset{\tau}{\underset{\pi}{\leftrightarrows}} \mathcal{M} \xrightarrow{\rho} \Delta^1 \times_{f, \mathcal{X}, \mathrm{ev}_0} \mathrm{Ar}^{cocart}(\mathcal{X})$$

where π restricts to the trivial fibrations $\mathcal{M}_0 \longrightarrow \underline{y} \times \{0\}$, $\mathcal{M}_1 \longrightarrow \underline{y} \times \{1\}$ of [Sha21a, Lem. 12.10] and ρ restricts to $\mathcal{M}_0 \longrightarrow \underline{x}$, $\mathcal{M}_1 \longrightarrow \underline{y}$. Thus π is a trivial fibration and we may choose a section τ which fixes $\underline{y} \times \{1\} \subset \mathcal{M}_1$. Then we let $\phi = \rho \circ \tau$.

2.3.3. **Theorem.** *Let $\mathcal{C}^\otimes \longrightarrow \mathcal{O}^\otimes$ be a fibration of $\mathcal{T}$-∞-operads. Let $x \in \mathcal{O}^\otimes$ be an object over $[f_+ : U_+ \to V] \in \underline{\mathbf{F}}_{\mathcal{T},*}$. Let $U \simeq U_1 \coprod ... \coprod U_n$ be an orbit decomposition, let $f_i : U_i \longrightarrow V$ denote the induced morphisms, and let $e_i : x \longrightarrow x_i$ be inert edges in $\mathcal{O}^\otimes$ lifting the characteristic morphisms $\chi_{[U_i \subset U]}$ in $\underline{\mathbf{F}}_{\mathcal{T},*}$. Then we have an equivalence of $\mathcal{T}^{/V}$-∞-categories*

$$\mathcal{C}^\otimes_{\underline{x}} \simeq \prod_f \left(\coprod_{1 \leq i \leq n} \mathcal{C}_{\underline{x_i}} \right) \simeq \prod_{1 \leq i \leq n} \left(\prod_{f_i} \mathcal{C}_{\underline{x_i}} \right).^{8}$$

Proof. Let

$$h_i : \Delta^1 \times \underline{x_i} \longrightarrow \Delta^1 \times_{e_i, \mathcal{O}^\otimes} \mathrm{Ar}^{cocart}(\mathcal{O}^\otimes) \longrightarrow \mathcal{O}^\otimes$$

be the homotopy associated to the edge e_i as defined as in Construction 2.3.2. Because h_i lands in $\mathcal{O}^\otimes_{ne}$, the pullback $\mathcal{C}^\otimes \times_{\mathcal{O}^\otimes} (\Delta^1 \times \underline{x_i}) \longrightarrow \Delta^1 \times \underline{U_i}$ is a cocartesian fibration. This corresponds to a $\mathcal{T}^{/U_i}$-functor $\rho^i : f_i^*(\mathcal{C}^\otimes_{\underline{x}}) \longrightarrow \mathcal{C}_{\underline{x_i}}$. Taking the coproduct of the ρ^i and taking the adjoint of that, we get a comparison $\mathcal{T}^{/V}$-functor

$$\rho : \mathcal{C}^\otimes_{\underline{x}} \longrightarrow \prod_f \left(\coprod_{1 \leq i \leq n} \mathcal{C}_{\underline{x_i}} \right).$$

We claim that ρ is a equivalence of $\mathcal{T}^{/V}$-∞-categories. We will check that for every object $[g : V' \to V]$, the fiber ρ_g is an equivalence. Consider the pullback square

$$\begin{array}{ccc} U' & \xrightarrow{g'} & U \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ V' & \xrightarrow{g} & V. \end{array}$$

Let $[U_+ \to V] \longrightarrow [U'_+ \to V']$ be the corresponding inert morphism in $\underline{\mathbf{F}}_{\mathcal{T},*}$ and let $x \longrightarrow x'$ be an inert lift of that morphism to $\mathcal{O}^\otimes$. Also let $U' \simeq U'_1 \coprod ... \coprod U'_m$ be an orbit decomposition and let $e'_j : x' \longrightarrow x'_j$ be inert morphisms lifting the characteristic morphisms $\chi_{[U'_j \subset U']}$.

Note that

$$(\mathcal{C}^\otimes_{\underline{x}})_g \simeq (\mathcal{C}^\otimes_{\underline{x'}})_{\mathrm{id}_{V'}} \simeq \mathcal{C}^\otimes_{x'}$$

and

$$\begin{aligned} \left(\prod_f \left(\coprod_{1 \leq i \leq n} \mathcal{C}_{\underline{x_i}} \right) \right)_g &\simeq \left(\prod_{f'} \left((g')^* \left(\coprod_{1 \leq i \leq n} \mathcal{C}_{\underline{x_i}} \right) \right) \right)_{\mathrm{id}_{V'}} \\ &\simeq \left((g')^* \left(\coprod_{1 \leq i \leq n} \mathcal{C}_{\underline{x_i}} \right) \right)_{\mathrm{id}_{U'}} \\ &\simeq \left(\coprod_{1 \leq j \leq m} \mathcal{C}_{\underline{x'_j}} \right)_{\mathrm{id}_{U'}} \\ &\simeq \coprod_{1 \leq j \leq m} \mathcal{C}_{x'_j} \end{aligned}$$

A diagram chase then shows that the functor $\rho_g : \mathcal{C}^\otimes_{x'} \longrightarrow \coprod_{1 \leq j \leq m} \mathcal{C}_{x'_j}$ implements the equivalence of condition (2) in Definition 2.1.7. □

[8] In this expression, each $\mathcal{C}_{\underline{x_i}}$ is a $\mathcal{T}^{/U_i}$-∞-category, their coproduct is a cocartesian fibration over $(\mathcal{T}^{/U})^{\mathrm{op}} = \underline{U} \simeq \coprod_{1 \leq i \leq n} \underline{U_i}$, the righthand product is taken in $\mathcal{T}^{/V}$-∞-categories, and the indexed product $\prod_f$ denotes the right adjoint to pullback along the induced functor $\underline{U} \longrightarrow \underline{V}$.

2.3.4. **Corollary** ($\mathcal{T}$-Segal condition). *Let $\mathcal{C}^{\otimes} \longrightarrow \underline{\mathbf{F}}_{\mathcal{T},*}$ be a $\mathcal{T}$-∞-operad. Then for every object $[U_+ \xrightarrow{f_+} V]$ in $\underline{\mathbf{F}}_{\mathcal{T},*}$, we have an equivalence of $\mathcal{T}^{/V}$-∞-categories*

$$\mathcal{C}^{\otimes}_{\underline{f_+}} \simeq \underline{\mathrm{Fun}}_{\mathcal{T}^{/V}}(\underline{U}, \mathcal{C}_{\underline{V}}).$$

Proof. In view of Theorem 2.3.3, we only need to note that $\underline{\mathrm{Fun}}_{\mathcal{T}^{/V}}(\underline{U}, -) \simeq \prod_f f^*$ as endofunctors of $\mathbf{Cat}_{\mathcal{T}^{/V}}$ and that for an orbit decomposition $U \simeq U_1 \coprod \dots \coprod U_n$, $\coprod_{1 \leq i \leq n} \mathcal{C}_{\underline{U_i}} \simeq \mathcal{C}_{\underline{U}} \simeq \underline{U} \times_{\underline{V}} \mathcal{C}_{\underline{V}}$. □

2.3.5. **Example.** Let $\mathcal{C}^{\otimes}$ be a $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-category. Then for every morphism $f : U \longrightarrow V$ of finite $\mathcal{T}$-sets, the norm functor $f_{\otimes} : \mathcal{C}_U \longrightarrow \mathcal{C}_V$ of Notation 2.2.4 canonically refines to a norm $\mathcal{T}^{/V}$-functor $\underline{\mathrm{Fun}}_{\mathcal{T}^{/V}}(\underline{U}, \mathcal{C}_{\underline{V}}) \longrightarrow \mathcal{C}_{\underline{V}}$. Indeed, if V is an orbit this is encoded by the cocartesian fibration $\mathcal{C}^{\otimes} \longrightarrow \underline{\mathbf{F}}_{\mathcal{T},*}$ in view of Corollary 2.3.4, and one extends to general V by taking coproducts.

We also have a reformulation of condition (3) in Definition 2.1.7 (or rather (3') in Remark 2.1.10), whose proof is the same as that of Theorem 2.3.3. Recall the notion of $\mathcal{T}$-mapping spaces from [Sha21a, §11].

2.3.6. **Notation.** Let $p : \mathcal{X} \longrightarrow \mathcal{B}$ be a $\mathcal{T}$-fibration, let $\alpha : a \longrightarrow b$ be a morphism in a fiber $\mathcal{B}_V$, and let $x, y \in \mathcal{X}$ so that $p(x) = a$ and $p(y) = b$. Then we define as a pullback of $\mathcal{T}^{/V}$-spaces

$$\underline{\mathrm{Map}}^{\alpha}_{\mathcal{X}}(x, y) := \underline{\alpha} \times_{\underline{\mathrm{Map}}_{\mathcal{B}}(a,b)} \underline{\mathrm{Map}}_{\mathcal{X}}(x, y).$$

2.3.7. **Proposition.** *Let $\mathcal{C}^{\otimes}$ be a $\mathcal{T}$-∞-operad and let notation be as in Remark 2.1.10. Then we have an equivalence of $\mathcal{T}^{/V}$-spaces*

$$\underline{\mathrm{Map}}^{\alpha_+}_{\mathcal{C}^{\otimes}}(x, y) \xrightarrow{\sim} \prod_g \left(\coprod_{W \in \mathrm{Orbit}(U')} \underline{\mathrm{Map}}^{(\alpha_W)_+}_{\mathcal{C}^{\otimes}}(x_W, y_W) \right).$$

Let us now apply the $\mathcal{T}$-Segal condition to characterize $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-categories as $\mathcal{T}$-commutative monoids in $\underline{\mathbf{Cat}}_{\mathcal{T}}$.

2.3.8. **Remark.** Under the equivalences (given by straightening and [Sha21a, Prop. 3.10], respectively)

$$\mathbf{Cat}^{cocart}_{/\underline{\mathbf{F}}_{\mathcal{T},*}} \simeq \mathrm{Fun}(\underline{\mathbf{F}}_{\mathcal{T},*}, \mathbf{Cat}) \simeq \mathrm{Fun}_T(\underline{\mathbf{F}}_{\mathcal{T},*}, \underline{\mathbf{Cat}}_{\mathcal{T}})$$

we see that $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-categories $\mathcal{C}^{\otimes}$ correspond to $\mathcal{T}$-commutative monoids M, i.e., $\mathcal{T}$-semiadditive $\mathcal{T}$-functors [Nar16, Def. 5.3], since by Corollary 2.3.4, M transforms

$$[U_+ \longrightarrow V] \simeq \coprod_{W \in \mathrm{Orbit}(U)} \coprod_{W \to V} I(W)_+ \in \mathbf{F}_{\mathcal{T}^{/V},*}$$

into

$$\prod_{W \in \mathrm{Orbit}(U)} \prod_{W \to V} \mathcal{C}_{\underline{W}} \simeq \prod_{W \in \mathrm{Orbit}(U)} \underline{\mathrm{Fun}}_{\mathcal{T}^{/V}}(\underline{W}, \mathcal{C}_{\underline{V}}) \simeq \underline{\mathrm{Fun}}_{\mathcal{T}^{/V}}(\underline{U}, \mathcal{C}_{\underline{V}}) \in \mathbf{Cat}_{\mathcal{T}^{/V}}.$$

Furthermore, in [Nar16, Thm. 6.5] the first author identified $\mathcal{T}$-commutative monoids with $\mathcal{T}$-Mackey functors. Using this, we can relate our notion of $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-category with that which appears in [BH21], wherein the norm functors of Notation 2.2.4 appear as the covariant part of categorical Mackey functor.

2.3.9. **Theorem.** *We have a canonical equivalence of ∞-categories*

$$\mathbf{Cat}^{\otimes}_{\mathcal{T}} \simeq \mathrm{Fun}^{\times}(\mathrm{Span}(\mathbf{F}_{\mathcal{T}}), \mathbf{Cat})$$

between the ∞-category $\mathbf{Cat}^{\otimes}_{\mathcal{T}}$ of $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-categories and the ∞-category of product-preserving functors from $\mathrm{Span}(\mathbf{F}_{\mathcal{T}})$ *to* $\mathbf{Cat}$.

Proof. In [Nar16, Thm. 6.5], the first author proved that given a $\mathcal{T}$-∞-category $\mathcal{D}$ with finite $\mathcal{T}$-limits, precomposition by the inclusion $\underline{\mathbf{F}}_{\mathcal{T},*} \longrightarrow \underline{\mathrm{Span}}(\mathbf{F}_{\mathcal{T}}) := \mathrm{Span}(\underline{\mathbf{F}}^{\vee}_{\mathcal{T}}; (\underline{\mathbf{F}}^{\vee}_{\mathcal{T}}), (\underline{\mathbf{F}}^{\vee}_{\mathcal{T}})^{tdeg})$ induces an equivalence of $\mathcal{T}$-∞-categories

$$\underline{\mathrm{Fun}}^{\times}_{\mathcal{T}}(\underline{\mathrm{Span}}(\mathbf{F}_{\mathcal{T}}), \mathcal{D}) \xrightarrow{\sim} \underline{\mathbf{CMon}}_{\mathcal{T}}(\mathcal{D}).$$

In particular, if $\mathcal{D} = \mathbf{Cat}_{\mathcal{T}}$, then as we just observed $\mathbf{CMon}_{\mathcal{T}}(\mathcal{D}) \simeq \mathbf{Cat}^{\otimes}_{\mathcal{T}}$, and passing to cocartesian sections we obtain

$$\mathrm{Fun}^{\times}_{\mathcal{T}}(\underline{\mathrm{Span}}(\mathbf{F}_{\mathcal{T}}), \underline{\mathbf{Cat}}_{\mathcal{T}}) \simeq \mathbf{Cat}^{\otimes}_{\mathcal{T}}.$$

Under the equivalence

$$\mathrm{Fun}_T(\underline{\mathrm{Span}}(\mathbf{F}_{\mathcal{T}}), \underline{\mathbf{Cat}}_{\mathcal{T}}) \simeq \mathrm{Fun}(\underline{\mathrm{Span}}(\mathbf{F}_{\mathcal{T}}), \mathbf{Cat})$$

let $\mathrm{Fun}'(\underline{\mathrm{Span}}(\mathbf{F}_T), \mathbf{Cat})$ denote the image of $\mathrm{Fun}^{\times}_T(\underline{\mathrm{Span}}(\mathbf{F}_{\mathcal{T}}), \mathbf{Cat}_{\mathcal{T}})$. Explicitly, functors in Fun' send cartesian edges to equivalences and fiberwise products to products, where cartesian edges in $\underline{\mathrm{Span}}(\mathbf{F}_{\mathcal{T}})$ are given by

$$\begin{array}{ccccc} U & \xleftarrow{=} & U & \xrightarrow{=} & U \\ \downarrow{=} & & \downarrow & & \downarrow \\ W & \xleftarrow{f} & V & \xrightarrow{=} & V \end{array}$$

in view of the adjunction

$$f^* : \mathrm{Span}(\mathbf{F}_{\mathcal{T}/W}) \rightleftarrows \mathrm{Span}(\mathbf{F}_{\mathcal{T}/V}) : f_!.$$

Let

$$s : \underline{\mathrm{Span}}(\mathbf{F}_{\mathcal{T}}) \longrightarrow \mathrm{Span}(\mathbf{F}_{\mathcal{T}})$$

denote the source map. Then we claim that precomposition by s induces an equivalence

$$\mathrm{Fun}^{\times}(\mathrm{Span}(\mathbf{F}_{\mathcal{T}}), \mathbf{Cat}) \xrightarrow{\simeq} \mathrm{Fun}'(\underline{\mathrm{Span}}(\mathbf{F}_{\mathcal{T}}), \mathbf{Cat})$$

with inverse given by right Kan extension.

First note that given a product preserving functor $G : \mathrm{Span}(\mathbf{F}_{\mathcal{T}}) \longrightarrow \mathbf{Cat}$, s^*G evidently sends cartesian edges to equivalences and fiberwise products to products. Conversely, suppose we have a functor $F : \underline{\mathrm{Span}}(\mathbf{F}_{\mathcal{T}}) \longrightarrow \mathbf{Cat}$ in Fun'. Let $X \in \mathrm{Span}(\mathbf{F}_{\mathcal{T}})$ be an object. Note that $(\mathbf{F}_{\mathcal{T}}^{\mathrm{op}})^{X/} \longrightarrow \mathrm{Span}(\mathbf{F}_{\mathcal{T}})^{X/}$ is an initial functor as it admits a right adjoint which sends a span $X \longleftarrow Z \longrightarrow Y$ to $X \longleftarrow Z$. Pulling back, we thereby obtain an initial functor

$$(\underline{\mathbf{F}}^{\mathrm{v}}_{\mathcal{T}})^{\mathrm{op}} \times_{\mathbf{F}_{\mathcal{T}}^{\mathrm{op}}} (\mathbf{F}_{\mathcal{T}}^{\mathrm{op}})^{X/} \longrightarrow \underline{\mathrm{Span}}(\mathbf{F}_{\mathcal{T}}) \times_{\mathrm{Span}(\mathbf{F}_{\mathcal{T}})} \mathrm{Span}(\mathbf{F}_{\mathcal{T}})^{X/}$$

and we are interested in computing the limit of the functor

$$F' = F \circ \mathrm{pr} : (\underline{\mathbf{F}}^{\mathrm{v}}_{\mathcal{T}})^{\mathrm{op}} \times_{\mathbf{F}_{\mathcal{T}}^{\mathrm{op}}} (\mathbf{F}_{\mathcal{T}}^{\mathrm{op}})^{X/} \longrightarrow (\underline{\mathbf{F}}^{\mathrm{v}}_{\mathcal{T}})^{\mathrm{op}} \longrightarrow \mathbf{Cat}.$$

By our assumption on F, F' is the right Kan extension of its restriction to $\mathcal{T}^{\mathrm{op}} \times_{\mathbf{F}_{\mathcal{T}}^{\mathrm{op}}} (\mathbf{F}_{\mathcal{T}}^{\mathrm{op}})^{X/}$ (where $\mathcal{T}^{\mathrm{op}} \longrightarrow (\underline{\mathbf{F}}^{\mathrm{v}}_{\mathcal{T}})^{\mathrm{op}}$ is the identity section). Indeed, given an object $I = [V \longleftarrow U \longrightarrow X]$ and an orbit decomposition $U \simeq \coprod_{i=1}^n U_i$, the n projection maps $I \longrightarrow I_i = [U_i = U_i \longrightarrow X]$ induce an equivalence

$$F'(I) = F([U \longrightarrow V]) \xrightarrow{\simeq} \prod_{i=1}^{n} F'(I_i) = \prod_{i=1}^{n} F([U_i = U_i]).$$

We conclude that the limit of F' is $\prod_{i \in I} F([X_i = X_i])$ for some orbit decomposition $X \simeq \coprod_{i \in I} X_i$, so $s_* F(X) \simeq \prod_{i \in I} F(\mathrm{id}_{X_i})$. Using this pointwise formula and a simple argument regarding the morphisms, we see that $s_* F$ preserves products and the counit and unit maps are equivalences. □

2.4. **Examples.** In this subsection, we discuss some basic examples of $\mathcal{T}$-∞-operads.

2.4.1. **Example** ($\mathcal{T}$-(co)cartesian $\mathcal{T}$-symmetric monoidal structures)**.** Let $\mathcal{C}$ be a $\mathcal{T}$-∞-category and let $\pi : \mathcal{C}^{\times} \longrightarrow \mathbf{F}_{\mathcal{T}}$ be the cartesian fibration defined as in [Sha21a, Prop. 5.12], so $(\mathcal{C}^{\times})_U \simeq \prod_{W \in \mathrm{Orbit}(U)} \mathcal{C}_W$ and the functoriality is given by restriction. Suppose $\mathcal{C}$ admits finite $\mathcal{T}$-coproducts. Then by [Sha21a, Prop. 5.12], π is a Beck–Chevalley fibration with cocartesian functoriality given by the coinduction functors, and by Barwick's unfurling construction [Bar17, §11], π straightens to a product-preserving functor $\mathrm{Span}(\mathbf{F}_{\mathcal{T}}) \longrightarrow \mathbf{Cat}$. Let

$$\mathcal{C}^{\amalg} \longrightarrow \underline{\mathbf{F}}_{\mathcal{T},*}$$

denote the resulting $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-category under the equivalence of Theorem 2.3.9. We call $\mathcal{C}^{\amalg}$ the $\mathcal{T}$-*cocartesian* $\mathcal{T}$-*symmetric monoidal structure* on $\mathcal{C}$.

Dually, suppose that $\mathcal{C}$ admits finite $\mathcal{T}$-products. Then by the dual of [Sha21a, Prop. 5.12], the vertical opposite $\pi^{\mathrm{vop}} : (\mathcal{C}^{\times})^{\mathrm{vop}} \longrightarrow \mathbf{F}_{\mathcal{T}}$ is a Beck–Chevalley fibration with cocartesian functoriality given by the (opposite of the) induction functors, and thus we obtain a product-preserving functor $\mathrm{Span}(\mathbf{F}_{\mathcal{T}}) \longrightarrow \mathbf{Cat}$. After postcomposing by the opposite automorphism of $\mathbf{Cat}$, let

$$\mathcal{C}^{\Pi} \longrightarrow \underline{\mathbf{F}}_{\mathcal{T},*}$$

denote the resulting $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-category under the equivalence of Theorem 2.3.9. We call $\mathcal{C}^{\Pi}$ the $\mathcal{T}$-*cartesian* $\mathcal{T}$-*symmetric monoidal structure* on $\mathcal{C}$.

2.4.2. **Example** (G-spectra)**.** Let $\mathbf{Gpd}_{\mathrm{fin}}$ be the $(2,1)$-category of finite groupoids and let

$$\mathbf{SH}^{\otimes} : \mathrm{Span}(\mathbf{Gpd}_{\mathrm{fin}}) \longrightarrow \mathbf{CAlg}(\mathbf{Cat}^{\mathrm{sift}})$$

denote the (restriction of the) functor of [BH21, §9.2]. Let G be a finite group and let

$$\omega_G : \mathrm{Span}(\mathbf{F}_G) \longrightarrow \mathrm{Span}(\mathbf{Gpd}_{\mathrm{fin}})$$

be the action groupoid functor. Let $(\underline{\mathbf{Sp}}^G)^{\otimes}$ be the G-symmetric monoidal G-∞-category associated to $\mathbf{SH}^{\otimes} \circ \omega_G$ under Theorem 2.3.9. Then $(\underline{\mathbf{Sp}}^G)^{\otimes}$ is the G-symmetric monoidal structure on $\underline{\mathbf{Sp}}^G$ that encodes the Hill–Hopkins–Ravenel norm functors.

2.4.3. **Example** (Trivial $\mathcal{T}$-∞-operad)**.** Let $\mathrm{Triv}^{\otimes}_{\mathcal{T}} \subset \underline{\mathbf{F}}_{\mathcal{T},*}$ be the wide subcategory on the inert edges. Then $\mathrm{Triv}^{\otimes}_{\mathcal{T}}$ is a $\mathcal{T}$-suboperad of $\underline{\mathbf{F}}_{\mathcal{T},*}$ such that the identity cocartesian section $I_+ : \mathcal{T}^{\mathrm{op}} \longrightarrow \underline{\mathbf{F}}_{\mathcal{T},*}$ restricts to a fully faithful functor into $\mathrm{Triv}^{\otimes}_{\mathcal{T}}$ and an equivalence onto $\mathrm{Triv}_{\mathcal{T}}$. We call $\mathrm{Triv}^{\otimes}_{\mathcal{T}}$ the *trivial* $\mathcal{T}$-∞-operad.

We claim that given any $\mathcal{T}$-∞-operad $\mathcal{C}^{\otimes}$, we have an equivalence

$$\underline{\mathbf{Alg}}_{\mathrm{Triv}_{\mathcal{T}},\mathcal{T}}(\mathcal{C}) \xrightarrow{\simeq} \mathcal{C}$$

implemented by restriction along I_+. To show this, we need the following lemma.

2.4.4. **Lemma.** *Let* $(\mathcal{O}^{\otimes}, p)$ *be a* $\mathcal{T}$-∞-*operad and let*

$$\mathcal{O}^{\otimes}_{ne} := \mathrm{Triv}^{\otimes}_{\mathcal{T}} \times_{\underline{\mathbf{F}}_{\mathcal{T},*}} \mathcal{O}^{\otimes}$$

be the wide subcategory on the inert edges. Let $F^{ne}_{\mathcal{O}} : \mathrm{Triv}^{\otimes}_{\mathcal{T}} \longrightarrow \mathbf{Cat}$ *be the functor classifying the cocartesian fibration* $p|_{\mathcal{O}^{\otimes}_{ne}}$. *Then* $F^{ne}_{\mathcal{O}}$ *is the right Kan extension of its restriction* $F_{\mathcal{O}}$ *along* $I_+ : \mathcal{T}^{\mathrm{op}} \longrightarrow \mathrm{Triv}^{\otimes}_{\mathcal{T}}$ *(which classifies the underlying* $\mathcal{T}$-∞-*category* $\mathcal{O}$*).*

Proof. Let $f_+ = [U_+ \longrightarrow V]$ be any object in $\mathrm{Triv}^{\otimes}_{\mathcal{T}}$ and let $\mathcal{J}^{\mathrm{op}} = \mathcal{T}^{\mathrm{op}} \times_{\mathrm{Triv}^{\otimes}_{\mathcal{T}}} (\mathrm{Triv}^{\otimes}_{\mathcal{T}})^{f_+/}$. We need to show that the natural map

$$F^{ne}_{\mathcal{O}}(f_+) \longrightarrow \lim(\theta : \mathcal{J}^{\mathrm{op}} \longrightarrow \mathcal{T}^{\mathrm{op}} \xrightarrow{F_{\mathcal{O}}} \mathbf{Cat})$$

is an equivalence. If we view $\mathrm{Orbit}(U)$ as a discrete category, then we have a functor $\phi : \mathrm{Orbit}(U) \longrightarrow \mathcal{J}^{\mathrm{op}}$ that sends W to $(W, \chi_{[W \subset U]})$, and by definition we have an equivalence

$$F^{ne}_{\mathcal{O}}(f_+) \xrightarrow{\simeq} \lim(\theta \circ \phi).$$

Consequently, it suffices to show that ϕ is right cofinal. Since $\mathrm{Triv}^{\otimes}_{\mathcal{T}} \simeq ((\underline{\mathbf{F}}^{\vee}_{\mathcal{T}})^{si})^{\mathrm{op}}$ under the inclusion into $\underline{\mathbf{F}}_{\mathcal{T},*} = \mathrm{Span}(\underline{\mathbf{F}}^{\vee}_{\mathcal{T}}; (\underline{\mathbf{F}}^{\vee}_{\mathcal{T}})^{si}, (\underline{\mathbf{F}}^{\vee}_{\mathcal{T}})^{tdeg})$, we may equivalently show that

$$\phi^{\mathrm{op}} : \mathrm{Orbit}(U)^{\mathrm{op}} = \mathrm{Orbit}(U) \longrightarrow \mathcal{J} \simeq \mathcal{T} \times_{(\underline{\mathbf{F}}^{\vee}_{\mathcal{T}})^{si}} ((\underline{\mathbf{F}}^{\vee}_{\mathcal{T}})^{si})^{/f}$$

is left cofinal. For this, we will apply Quillen's Theorem A. Let

$$\overline{\alpha} = \left(\begin{array}{ccc} X & \xrightarrow{\alpha} & U \\ \downarrow{=} & & \downarrow{f} \\ X & \longrightarrow & V \end{array} \right)$$

be any object in $\mathcal{J}$. Then since $\mathrm{Orbit}(U)$ is discrete, we have an equivalence

$$\mathrm{Orbit}(U) \times_{\mathcal{J}} \mathcal{J}^{\overline{\alpha}/} \simeq \coprod_{W \in \mathrm{Orbit}(U)} \mathrm{Map}_{\mathcal{J}}(\overline{\alpha}, \chi_{[W \subset U]}).$$

If we let W be the orbit in U that α factors through, then for all other $W' \in \mathrm{Orbit}(X)$, we have

$$\mathrm{Map}_{\mathcal{J}}(\overline{\alpha}, \chi_{[W' \subset U]}) = \emptyset.$$

To compute the remaining mapping space, observe that we have a homotopy pullback square

$$\begin{array}{ccc} \mathrm{Map}_{\mathcal{J}}(\overline{\alpha}, \chi_{[W \subset U]}) & \longrightarrow & \mathrm{Map}_{(\underline{\mathbf{F}}^{\mathrm{v}}_{\mathcal{T}})^{si}}(\mathrm{id}_X, \mathrm{id}_W) \simeq \mathrm{Map}_{\underline{\mathbf{F}}^{\mathrm{v}}_{\mathcal{T}}}(\mathrm{id}_X, \mathrm{id}_W) \\ \downarrow & & \downarrow \\ * & \xrightarrow{\quad \overline{\alpha} \quad} & \mathrm{Map}_{(\underline{\mathbf{F}}^{\mathrm{v}}_{\mathcal{T}})^{si}}(\mathrm{id}_X, f) \simeq \mathrm{Map}_{\underline{\mathbf{F}}^{\mathrm{v}}_{\mathcal{T}}}(\mathrm{id}_X, f) \end{array}$$

where for the righthand equivalences we use our assumption that $\mathcal{T}$ is orbital. But the righthand vertical map identifies with

$$\mathrm{Map}_{\mathbf{F}_{\mathcal{T}}}(X, W) \longrightarrow \mathrm{Map}_{\mathbf{F}_{\mathcal{T}}}(X, U) \times_{\mathrm{Map}_{\mathbf{F}_{\mathcal{T}}}(X,V)} \mathrm{Map}_{\mathbf{F}_{\mathcal{T}}}(X, V) \simeq \mathrm{Map}_{\mathbf{F}_{\mathcal{T}}}(X, U)$$

and is hence an equivalence. We conclude that $\mathrm{Orbit}(U) \times_{\mathcal{J}} \mathcal{J}^{\overline{\alpha}/}$ is contractible, so ϕ^{op} is left cofinal. □

2.4.5. **Corollary.** *Let $\mathcal{C}$ be a $\mathcal{T}$-∞-category, let $F_{\mathcal{C}} : \mathcal{T}^{\mathrm{op}} \longrightarrow \mathbf{Cat}$ be the functor that classifies $\mathcal{C}$, and let $q : \mathrm{Triv}_{\mathcal{T}}(\mathcal{C})^{\otimes} \longrightarrow \mathrm{Triv}^{\otimes}_{\mathcal{T}}$ be the cocartesian fibration classified by the right Kan extension of $F_{\mathcal{C}}$ along $I_+ : \mathcal{T}^{\mathrm{op}} \longrightarrow \mathrm{Triv}^{\otimes}_{\mathcal{T}}$.*[9] *Then $\mathrm{Triv}_{\mathcal{T}}(\mathcal{C})^{\otimes}$ is a $\mathcal{T}$-∞-operad and for any $\mathcal{T}$-∞-operad $\mathcal{O}^{\otimes}$, we have an equivalence of $\mathcal{T}$-∞-categories*

$$\underline{\mathbf{Alg}}_{\mathcal{T}}(\mathrm{Triv}_{\mathcal{T}}(\mathcal{C}), \mathcal{O}) \xrightarrow{\simeq} \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{C}, \mathcal{O})$$

implemented by restriction along I_+.

Proof. By Lemma 2.4.4, we have an equivalence of ∞-categories between $\mathrm{Triv}_{\mathcal{T}}$-monoidal $\mathcal{T}$-∞-categories and the full subcategory of $\mathrm{Fun}(\mathrm{Triv}^{\otimes}_{\mathcal{T}}, \mathbf{Cat})$ spanned by those functors right Kan extended from $\mathcal{T}^{\mathrm{op}}$ along I_+, so in particular $\mathrm{Triv}_{\mathcal{T}}(\mathcal{C})^{\otimes}$ is a $\mathcal{T}$-∞-operad. For the second statement, since restriction along I_+ is a $\mathcal{T}$-functor, it suffices to show an equivalence of fibers over every orbit $V \in \mathcal{T}$, so after replacing $\mathcal{T}$ by $\mathcal{T}^{/V}$ we reduce to the claim that

$$\mathbf{Alg}_{\mathcal{T}}(\mathrm{Triv}_{\mathcal{T}}(\mathcal{C}), \mathcal{O}) \simeq \mathrm{Fun}^{cocart}_{/\mathrm{Triv}^{\otimes}_{\mathcal{T}}}(\mathrm{Triv}_{\mathcal{T}}(\mathcal{C})^{\otimes}, \mathcal{O}^{\otimes}_{ne}) \longrightarrow \mathrm{Fun}_{\mathcal{T}}(\mathcal{C}, \mathcal{O})$$

is an equivalence of ∞-categories. But this follows immediately from Lemma 2.4.4. □

2.4.6. **Example.** By Corollary 2.4.5, the $\mathcal{T}$-suboperads of the trivial $\mathcal{T}$-∞-operad are in bijective correspondence with sieves of $\mathcal{T}$. For instance, we have that the initial $\mathcal{T}$-∞-operad $\mathrm{Triv}_{\mathcal{T}}(\emptyset)^{\otimes}$ corresponds to $\emptyset \subset \mathcal{T}$ and identifies with the full subcategory of $\underline{\mathbf{F}}_{\mathcal{T},*}$ on objects $[\emptyset_+ \longrightarrow V]$.

2.4.7. **Example** (Indexing systems and the family of commutative $\mathcal{T}$-∞-operads)**.** Clearly $\underline{\mathbf{F}}_{\mathcal{T},*}$ is itself a $\mathcal{T}$-∞-operad, which deserves to be called the *$\mathcal{T}$-commutative $\mathcal{T}$-∞-operad* $\mathrm{Com}^{\otimes}_{\mathcal{T}}$. Note that the identity cocartesian section $I_+ : \mathcal{T}^{\mathrm{op}} \longrightarrow \mathrm{Com}^{\otimes}_{\mathcal{T}}$ restricts to an equivalence $\mathcal{T}^{\mathrm{op}} \xrightarrow{\simeq} \mathrm{Com}_{\mathcal{T}}$.

In the parametrized setting, we may further define a family of $\mathcal{T}$-suboperads of $\mathrm{Com}^{\otimes}_{\mathcal{T}}$ so as to encode different flavors of parametrized commutativity. First, define the *minimal* $\mathcal{T}$-commutative $\mathcal{T}$-∞-operad $\mathrm{Com}^{\otimes}_{\mathcal{T}\simeq}$ to be the wide subcategory of $\underline{\mathbf{F}}_{\mathcal{T},*}$ containing all morphisms

$$\begin{array}{ccccc} U & \longleftarrow & Z & \xrightarrow{m} & X \\ \downarrow & & \downarrow & & \downarrow \\ V & \longleftarrow & Y & \xrightarrow{=} & Y. \end{array}$$

where m is a coproduct of fold maps (including possibly empty fold maps). In other words, if we let ∇ denote the collection of fold maps and $(\underline{\mathbf{F}}^{\mathrm{v}}_{\mathcal{T}})^{\nabla:tdeg} \subset \underline{\mathbf{F}}^{\mathrm{v}}_{\mathcal{T}}$ the wide subcategory on morphisms with source in ∇ and target degenerate, then

$$\mathrm{Com}^{\otimes}_{\mathcal{T}\simeq} = \mathrm{Span}(\underline{\mathbf{F}}^{\mathrm{v}}_{\mathcal{T}}; (\underline{\mathbf{F}}^{\mathrm{v}}_{\mathcal{T}})^{si}, (\underline{\mathbf{F}}^{\mathrm{v}}_{\mathcal{T}})^{\nabla:tdeg}),$$

where we use that ∇ is stable under pullback by summand inclusions, and $\mathrm{Com}^{\otimes}_{\mathcal{T}\simeq}$ is classified by the functor $\mathcal{T}^{\mathrm{op}} \longrightarrow \mathbf{Cat}$ that sends an orbit V to $\mathrm{Span}(\mathbf{F}_{\mathcal{T}/V}; \mathbf{F}^{si}_{\mathcal{T}/V}, \mathbf{F}^{\nabla}_{\mathcal{T}/V})$. Since $\mathrm{Com}^{\otimes}_{\mathcal{T}\simeq}$ contains all inert edges in $\mathrm{Com}^{\otimes}_{\mathcal{T}}$ and $\mathrm{Com}_{\mathcal{T}\simeq} \simeq \mathcal{T}^{\mathrm{op}}$, to verify that $\mathrm{Com}^{\otimes}_{\mathcal{T}\simeq}$ is a $\mathcal{T}$-suboperad it only remains to check condition (3') of Remark 2.1.10. But this condition is satisfied since a map $\alpha : U \longrightarrow U'$ of finite $\mathcal{T}$-sets is a fold map if and only if for all $W \in \mathrm{Orbit}(U')$, the pullback $\alpha_W : U \times_{U'} W \longrightarrow W$ is a fold map.

[9] Using [Sha21a, Ex. 2.26], we could give a definition of $\mathrm{Triv}_{\mathcal{T}}(\mathcal{C})^{\otimes}$ at the level of marked simplicial sets, without passing through straightening and unstraightening.

Now suppose that we want to define a $\mathcal{T}$-∞-operad $\mathcal{O}^{\otimes}$ such that we have $\mathcal{T}$-operadic inclusions

$$\mathrm{Com}^{\otimes}_{\mathcal{T}^{\simeq}} \subset \mathcal{O}^{\otimes} \subset \mathrm{Com}^{\otimes}_{\mathcal{T}}.$$

Since $\mathrm{Com}_{\mathcal{T}^{\simeq}} = \mathrm{Com}_{\mathcal{T}} \simeq \mathcal{T}^{\mathrm{op}}$, the only constraint on $\mathcal{O}^{\otimes}$ to be a $\mathcal{T}$-suboperad arises from condition (3'). In other words, to specify $\mathcal{O}^{\otimes}$ we may as well specify the morphisms $\alpha : U \longrightarrow V$ with V an orbit that we wish to be active. We already have that all fold maps are active, so in particular all summand inclusions are active. Furthermore, as observed in Remark 2.1.11, for any orbit $W \subset U$, the composite map $W \subset U \xrightarrow{\alpha} V$ yields an operadic composition map

$$\mathrm{Mul}_{\mathcal{O}}^{W \subset U} \times \mathrm{Mul}_{\mathcal{O}}^{\alpha} \simeq * \times \mathrm{Mul}_{\mathcal{O}}^{\alpha} \longrightarrow \mathrm{Mul}_{\mathcal{O}}^{\alpha|_W},$$

so if α is active, we must have that $\alpha|_W$ is active for all $W \in \mathrm{Orbit}(U)$. The converse holds by a similar argument since α factors as

$$U \xrightarrow{\simeq} \coprod_{W \in \mathrm{Orbit}(U)} W \xrightarrow{\coprod \alpha|_W} \coprod_{W \in \mathrm{Orbit}(U)} V \xrightarrow{\nabla} V .$$

We thereby reduce to specifying whether or not morphisms $\alpha : W \longrightarrow V$ are active for both W and V orbits. Moreover, by examining Remark 2.1.11 again we see that the only constraints are:

(1) The active morphisms contain all equivalences and are closed under composition, so assemble to a subcategory $\mathcal{I} \subset \mathcal{T}$ such that $\mathcal{I}$ contains the maximal subgroupoid $\mathcal{T}^{\simeq}$ of $\mathcal{T}$.
(2) The active morphisms are closed under base-change, in the sense that for any commutative square

$$\begin{array}{ccc} W' & \longrightarrow & W \\ \downarrow{\scriptstyle \alpha'} & & \downarrow{\scriptstyle \alpha} \\ V' & \longrightarrow & V \end{array}$$

such that the map $W' \longrightarrow V' \times_V W$ is a summand inclusion, if α is in $\mathcal{I}$ then α' is in $\mathcal{I}$.

2.4.8. **Definition.** A $\mathcal{T}$-*indexing system* is a subcategory $\mathcal{I}$ of $\mathcal{T}$ that satisfies the above conditions (1) and (2).

2.4.9. **Remark.** An indexing system $\mathcal{I}$ is the same data as a subcategory $\overline{\mathcal{I}} \subset \mathbf{F}_{\mathcal{T}}$ such that:

(1) $\overline{\mathcal{I}}$ contains the maximal subgroupoid $\mathbf{F}_{\mathcal{T}}^{\simeq}$.
(2) Morphisms in $\overline{\mathcal{I}}$ are closed under base-change and binary coproducts.
(3) $\overline{\mathcal{I}}$ contains all fold maps (and hence all summand inclusions).

Indeed, the assignment $\overline{\mathcal{I}} \rightsquigarrow \mathcal{I} = \overline{\mathcal{I}} \times_{\mathbf{F}_{\mathcal{T}}} \mathcal{T}$ is seen to identify the two notions, with inverse given by taking the finite coproduct completion of $\mathcal{I}$.

2.4.10. **Definition.** Let $\mathcal{I}$ be a $\mathcal{T}$-indexing system and let $(\underline{\mathbf{F}}_{\mathcal{T}}^{\mathrm{v}})^{\mathcal{I}:tdeg} \subset \underline{\mathbf{F}}_{\mathcal{T}}^{\mathrm{v}}$ be the wide subcategory on morphisms with source in $\overline{\mathcal{I}}$ and target degenerate. We then define the $\mathcal{I}$-*commutative* $\mathcal{T}$-∞-*operad* to be

$$\mathrm{Com}^{\otimes}_{\mathcal{I}} := \mathrm{Span}(\underline{\mathbf{F}}_{\mathcal{T}}^{\mathrm{v}}; (\underline{\mathbf{F}}_{\mathcal{T}}^{\mathrm{v}})^{si}, (\underline{\mathbf{F}}_{\mathcal{T}}^{\mathrm{v}})^{\mathcal{I}:tdeg}).$$

More generally, we define a *commutative* $\mathcal{T}$-∞-operad to be any $\mathcal{T}$-suboperad of $\mathrm{Com}^{\otimes}_{\mathcal{T}}$ containing $\mathrm{Com}^{\otimes}_{\mathcal{T}^{\simeq}}$.

The above analysis confirms the following proposition.

2.4.11. **Proposition.** *The assignment $\mathcal{I} \rightsquigarrow \mathrm{Com}^{\otimes}_{\mathcal{I}}$ implements an inclusion-preserving bijection between $\mathcal{T}$-indexing systems and commutative $\mathcal{T}$-∞-operads.*

2.4.12. **Remark.** Let $\mathcal{T} = \mathbf{O}_G$. A G-indexing system I in the sense of Blumberg-Hill [BH15, Def. 3.22] as reformulated by Rubin [Rub21, Def. 2.12] is a collection $\{I(H)\}$ of finite H-sets for every subgroup $H \leq G$ such that $I(H)$ contains all finite H-sets with trivial H-action and satisfies the following closure properties:

(1) If $U \in I(H)$ and $U' \cong U$, then $U' \in I(H)$.
(2) For every subgroup $K \leq H$, if $U \in I(H)$ then $\mathrm{res}^H_K U \in I(K)$.
(3) For every conjugate $H' = gHg^{-1}$ of H, if $U \in I(H)$ then its conjugate $U' \in I(H')$.
(4) If $U \in I(H)$ and $U' \subset U$, then $U' \in I(H)$.
(5) If $U, U' \in I(H)$, then $U \coprod U' \in I(H)$.
(6) For any subgroup $K \leq H$, if $U \in I(K)$ and $H/K \in I(H)$ then $\mathrm{ind}^H_K U \in I(H)$.

In [BH15, Thm. 3.17], it was shown that G-indexing systems are in bijective correspondence with subcategories of $\mathbf{F}_G$ satisfying the conditions of Remark 2.4.9 (and thus with the $\mathbf{O}_G$-indexing systems of Definition 2.4.8). For the convenience of the reader, we review this correspondence. Note that under the equivalences $\mathbf{F}_H \simeq \mathbf{F}_G^{/(G/H)}$, given a subgroup $K \leq H$, induction corresponds to postcomposition by $G/K \longrightarrow G/H$. Therefore, given a G-indexing system I, we may define a wide subcategory $\mathcal{I} \subset \mathbf{O}_G$ to be the subcategory whose morphisms $f : V \longrightarrow W \cong G/H$ are such that $f \in I(H)$. The enumerated conditions then imply that $\mathcal{I}$ is a $\mathbf{O}_G$-indexing system, using closure under restriction and inclusion to validate the base-change condition.

Conversely, suppose $\mathcal{I}$ is a $\mathbf{O}_G$-indexing system and let $\overline{\mathcal{I}} \subset \mathbf{F}_G$ be the subcategory generated by $\mathcal{I}$ as in Remark 2.4.9. Let $I(H)$ be the subset of objects of $\mathbf{F}_H$ given by morphisms in $\overline{\mathcal{I}}$ with target G/H under $\mathbf{F}_H \simeq \mathbf{F}_G^{/(G/H)}$. Then one sees that I is a G-indexing system and these assignments are mutually inverse – note that condition (5) holds since given $U, U' \longrightarrow G/H$, the coproduct in $\mathbf{F}_H$ is given by the composition $U \coprod U' \longrightarrow G/H \coprod G/H \longrightarrow G/H$.

Consequently, by the work of Bonventre–Pereira [BP21], Gutiérrez–White [GW18], and Rubin [Rub21], we see that the commutative G-∞-operads are in bijection with the N_∞-operads of Blumberg–Hill.

A straightforward adaptation of the proof of Theorem 2.3.9 shows the following.

2.4.13. **Definition.** Given a $\mathcal{T}$-indexing system $\mathcal{I}$, let $\mathbf{Cat}_{\mathcal{I}}^{\otimes}$ be the ∞-category of $\mathcal{I}$-symmetric monoidal $\mathcal{T}$-∞-categories and $\mathcal{I}$-symmetric monoidal $\mathcal{T}$-functors thereof.

2.4.14. **Theorem.** *Let $\mathcal{I}$ be a $\mathcal{T}$-indexing system. We then have a canonical equivalence*

$$\mathbf{Cat}_{\mathcal{I}}^{\otimes} \simeq \mathrm{Fun}^{\times}(\mathrm{Span}(\mathbf{F}_{\mathcal{T}}; \mathbf{F}_{\mathcal{T}}, \overline{\mathcal{I}}), \mathbf{Cat}).$$

2.4.15. **Corollary.** *For the minimal indexing system $\mathcal{I} = \mathcal{T}^{\simeq}$, we have a canonical identification of $\mathcal{T}^{\simeq}$-symmetric monoidal $\mathcal{T}$-∞-categories with $\mathcal{T}^{\mathrm{op}}$-cocartesian families of symmetric monoidal ∞-categories (*[Lur17, Def. 4.8.3.1]*).*

2.5. **T-operadic nerve.** In this subsection, we suppose that $\mathcal{T}$ is equivalent to the nerve of a 1-category T. For example, by the following proposition we could take $\mathcal{T}$ to be any atomic orbital ∞-category that admits a final object.

2.5.1. **Proposition.** *Suppose $\mathcal{T}$ is an atomic orbital ∞-category that admits a final object $*$. Then $\mathcal{T}$ is equivalent to the nerve of a 1-category.*

Proof. By [Lur09, Prop. 2.3.4.18] it suffices to show that the mapping spaces of $\mathcal{T}$ are 0-truncated, or equivalently that the essentially unique maps $V \longrightarrow *$ are 0-truncated for all $V \in \mathcal{T}$. By [Lur09, Lem. 5.5.6.15], this occurs if and only if the diagonal $\delta : V \longrightarrow V \times V$ in $\mathbf{F}_{\mathcal{T}}$ is (-1)-truncated. But since $\mathcal{T}$ is atomic and δ is split by either projection to V, it follows that δ is a summand inclusion and hence a monomorphism. □

Correspondingly, let $\mathbf{F}_T$ denote the subcategory of the category of **Set**-valued presheaves on T spanned by the finite coproducts of representables, so that $\mathbf{F}_{\mathcal{T}} \simeq N(\mathbf{F}_T)$.

2.5.2. **Remark.** If T is a 1-category, then the *a priori* $(2,1)$-category

$$\underline{\mathbf{F}}_{T,*} := \mathrm{Span}(\mathbf{F}_T^{\Delta^1} \times_{\mathbf{F}_T} T, (\mathbf{F}_T^{\Delta^1})^{tdeg}, (\mathbf{F}_T^{\Delta^1})^{si})$$

is enriched in setoids and therefore equivalent to a 1-category. Indeed, the only automorphisms of spans of the form

$$\begin{array}{ccccc} U & \longleftarrow & \tilde{U} & \longrightarrow & U' \\ \downarrow & & \downarrow & & \downarrow \\ V & \longleftarrow & V' & = & V' \end{array}$$

where the left square is in $(\mathbf{F}_T^{\Delta^1})^{si}$ are identities. In what follows, we will implicitly make a choice of 1-categorical model for $\underline{\mathbf{F}}_{T,*}$ by picking a representative for every equivalence class of morphisms.

Our goal is to indicate how to prescribe the data of a $\mathcal{T}$-∞-operad in terms of the stricter data of a *simplicial colored T-operad*, which will be defined along the lines suggested by Remark 2.1.11. To concisely state its definition, we first need to introduce some notation.

2.5.3. **Notation.** Let $A\mathbf{F}_T \subseteq \mathrm{Ar}(\mathbf{F}_T)$ denote the wide subcategory of the arrow category whose morphisms are cartesian squares. Suppose that $\mathrm{ob}O \longrightarrow \mathbf{F}_T$ is a Grothendieck fibration fibered in sets, and let $\mathrm{ob}O(U)$ denote the fiber of $\mathrm{ob}O$ over $U \in \mathbf{F}_T$. We then write

$$A^O\mathbf{F}_T \coloneqq A\mathbf{F}_T \times_{(\mathbf{F}_T\times\mathbf{F}_T)} (\mathrm{ob}O \times \mathrm{ob}O)$$

for the category whose objects are triples $(f : U \longrightarrow V,\, x \in \mathrm{ob}O(U),\, y \in \mathrm{ob}O(V))$ and whose morphisms are cartesian squares

$$\begin{array}{ccc} U' & \xrightarrow{\phi} & U \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ V' & \xrightarrow{\psi} & V \end{array}$$

such that $x' = \phi^*x$ and $y' = \psi^*y$. We have functors

$$1 : \mathrm{ob}O \longrightarrow A^O\mathbf{F}_T, \quad (x \in \mathrm{ob}O(U)) \mapsto (\mathrm{id}_U, x, x),$$

$$\circ : A^O\mathbf{F}_T \times_{\mathrm{ob}O} A^O\mathbf{F}_T \longrightarrow A^O\mathbf{F}_T, \quad (f : U \longrightarrow V, g : V \longrightarrow W, x, y, z) \mapsto (gf : U \longrightarrow W, x, z).$$

2.5.4. **Definition.** A (fibrant) *simplicial colored T-operad O* is the data of

(1) A 'T-set of colors', given as a Grothendieck fibration fibered in sets

$$\mathrm{ob}O \longrightarrow \mathbf{F}_T$$

classified by a functor $\mathbf{F}_T^{\mathrm{op}} \longrightarrow \mathbf{Set}$ preserving finite products.

(2) A collection of spaces of multimorphisms, packaged into a functor

$$\mathrm{Mul}_O : (A^O\mathbf{F}_T)^{\mathrm{op}} \longrightarrow \mathbf{sSet}, \quad (f : U \longrightarrow V,\, x \in \mathrm{ob}O(U),\, y \in \mathrm{ob}O(V)) \mapsto \mathrm{Mul}_O^f(x,y)$$

that preserves finite products and is valued in Kan complexes.[10]

(3) A distinguished 'identity' for Mul_O, given by a natural transformation

$$1 : * \longrightarrow \mathrm{Mul}_O^{\mathrm{id}_U}(x,x)$$

of functors $(\mathrm{ob}O)^{\mathrm{op}} \longrightarrow \mathbf{sSet}$, where the right hand side is the composition

$$(\mathrm{ob}O)^{\mathrm{op}} \xrightarrow{1} A^O\mathbf{F}_T^{\mathrm{op}} \xrightarrow{\mathrm{Mul}} \mathbf{sSet}\,.$$

(4) A 'composition law' for Mul_O, given by a natural transformation

$$\circ : \mathrm{Mul}_O^f(x,y) \times \mathrm{Mul}_O^g(y,z) \longrightarrow \mathrm{Mul}_O^{gf}(x,z)$$

of functors $(A^O\mathbf{F}_T \times_{\mathrm{ob}O} A^O\mathbf{F}_T)^{\mathrm{op}} \longrightarrow \mathbf{sSet}$, where the left hand side is the composition

$$(A^O\mathbf{F}_T \times_{\mathrm{ob}O} A^O\mathbf{F}_T)^{\mathrm{op}} \longrightarrow (A^O\mathbf{F}_T \times A^O\mathbf{F}_T)^{\mathrm{op}} \xrightarrow{\mathrm{Mul}\times\mathrm{Mul}} \mathbf{sSet} \times \mathbf{sSet} \xrightarrow{\times} \mathbf{sSet}\,,$$

and the right hand side is the composition

$$(A^O\mathbf{F}_T \times_{\mathrm{ob}O} A^O\mathbf{F}_T)^{\mathrm{op}} \xrightarrow{\circ} A^O\mathbf{F}_T^{\mathrm{op}} \xrightarrow{\mathrm{Mul}} \mathbf{sSet}\,.$$

These data are required to satisfy the following compatibilities:

- **Unitality**: The compositions

$$\mathrm{Mul}_O^f(x,y) \xrightarrow{(\mathrm{id},1_y)} \mathrm{Mul}_O^f(x,y) \times \mathrm{Mul}_O^{\mathrm{id}_V}(y,y) \xrightarrow{\circ} \mathrm{Mul}_O^f(x,y)$$

and

$$\mathrm{Mul}_O^f(x,y) \xrightarrow{(1_x,\mathrm{id})} \mathrm{Mul}_O^{\mathrm{id}_U}(x,x) \times \mathrm{Mul}_O^f(x,y) \xrightarrow{\circ} \mathrm{Mul}_O^f(x,y)$$

are the identity natural transformation.

- **Associativity** The following diagram is commutative

$$\begin{array}{ccc} \mathrm{Mul}_O^f(x,y) \times \mathrm{Mul}_O^g(y,z) \times \mathrm{Mul}_O^h(z,t) & \xrightarrow{(\circ,\mathrm{id})} & \mathrm{Mul}_O^{gf}(x,z) \times \mathrm{Mul}_O^h(z,t) \\ \downarrow{\scriptstyle (\mathrm{id},\circ)} & & \downarrow{\scriptstyle \circ} \\ \mathrm{Mul}_O^f(x,y) \times \mathrm{Mul}_O^{hg}(y,t) & \xrightarrow{\circ} & \mathrm{Mul}_O^{hgf}(x,t) \end{array}.$$

[10] If V is an orbit, we thus obtain a $T^{/V}$-space $\underline{\mathrm{Mul}}_O^f(x,y) : (T^{/V})^{\mathrm{op}} \longrightarrow \mathbf{sSet}$ by precomposing Mul_O with the functor $T^{/V} \longrightarrow A^O\mathbf{F}_T$ over $\mathbf{F}_T$ determined by (f,x,y) – indeed, one has an equivalence $(A^O\mathbf{F}_T)^{/(f,x,y)} \simeq (\mathbf{F}_T)^{/V}$.

2.5.5. **Construction.** From the data of Definition 2.5.4 we will build a simplicial category $O^{\otimes}$ over $\underline{\mathbf{F}}_{T,*}$ as follows. We let the objects of $O^{\otimes}$ be the pairs $([U_+ \longrightarrow V], x)$, where $[U_+ \longrightarrow V]$ is an object of $\underline{\mathbf{F}}_{T,*}$ and $x \in \mathrm{ob}O(U)$, and we define as mapping simplicial sets

$$\mathrm{Map}_{O^{\otimes}}(([U_+ \longrightarrow V], x), ([U'_+ \longrightarrow V'], x')) \coloneqq \coprod_{U \overset{i}{\longleftarrow} U_0 \overset{f}{\longrightarrow} U'} \mathrm{Mul}^f(i^*x, x')$$

where the coproduct is indexed by the set of all maps $[U_+ \longrightarrow V] \longrightarrow [U'_+ \longrightarrow V']$ in $\underline{\mathbf{F}}_{T,*}$. The identity of $([U_+ \longrightarrow V], x)$ is given by $1_{(U,x)} \in \mathrm{Mul}^{\mathrm{id}_U}(x, x)$. If

$$\begin{array}{ccccccc} & & & U_1 & & & \\ & & \overset{j'}{\swarrow} & & \overset{f'}{\searrow} & & \\ & U_0 & & & & U_0' & \\ \overset{i}{\swarrow} & & \overset{f}{\searrow} & & \overset{j}{\swarrow} & & \overset{g}{\searrow} \\ U & & & U' & & & U'' \end{array}$$

is a diagram representing a composition in $\underline{\mathbf{F}}_{T,*}$, composition over it is given by

$$\mathrm{Mul}^f(i^*x, x') \times \mathrm{Mul}^g(j^*x', x'') \longrightarrow \mathrm{Mul}^{f'}((j')^*i^*x, j^*x') \times \mathrm{Mul}^g(j^*x', x'') \longrightarrow \mathrm{Mul}^{gf'}((ij')^*x, x'').$$

Verifying that this satisfies associativity and unitality is left as an exercise for the reader.

2.5.6. **Proposition.** *The map $N(O^{\otimes}) \longrightarrow N(\underline{\mathbf{F}}_{T,*}) \simeq \underline{\mathbf{F}}_{\mathcal{T},*}$ is a $\mathcal{T}$-∞-operad.*

Proof. Using [Lur09, Prop. 2.4.1.10] we see that the above map is an inner fibration and that its restriction over the subcategory of inert edges is a cocartesian fibration. Then remaining properties are true because $\mathrm{ob}O$ and Mul preserve finite products. ☐

2.6. **Model structures.** In this subsection, we introduce a model structure for $\mathcal{T}$-∞-operads by means of Lurie's theory of categorical patterns ([Lur17, Def. B.0.19]). For a $\mathcal{T}$-∞-operad $\mathcal{O}^{\otimes}$, let $\mathrm{Ne} \subset (\mathcal{O}^{\otimes})_1$ denote the subset of inert morphisms.

2.6.1. **Definition.** We define categorical patterns $\mathfrak{P}_{\mathcal{T}}$ and $\mathfrak{P}_{\mathcal{T}}^{\otimes}$ on $\underline{\mathbf{F}}_{\mathcal{T},*}$ as follows. For each collection of morphisms $\underline{\alpha} = \{\alpha_i : U_i \longrightarrow V\}_{i=1}^n$ in $\mathcal{T}$, let $\alpha : U = \coprod_{i=1}^n U_i \xrightarrow{(\alpha_i)} V$ and define a morphism

$$f_\alpha : (n^{\lhd})^{\sharp} \longrightarrow (\underline{\mathbf{F}}_{\mathcal{T},*}, \mathrm{Ne})$$

(for $n = \{1, ..., n\}$ regarded as a discrete category) that sends the cone point v to $[U_+ \to V]$, $i \in n$ to $[U_{i+} \to U_i]$, and $v \longrightarrow i$ to the characteristic morphism $\chi_{[U_i \subset U]}$. Then let A be the set of the $\underline{\alpha}$ and let

$$\mathfrak{P}_{\mathcal{T}} = (\mathrm{Ne}, \mathcal{A}ll, \{f_\alpha : n^{\lhd} \longrightarrow \underline{\mathbf{F}}_{\mathcal{T},*}\}_{\underline{\alpha} \in A}),$$
$$\mathfrak{P}_{\mathcal{T}}^{\otimes} = (\mathcal{A}ll, \mathcal{A}ll, \{f_\alpha : n^{\lhd} \longrightarrow \underline{\mathbf{F}}_{\mathcal{T},*}\}_{\underline{\alpha} \in A}).$$

Furthermore, for any $\mathcal{T}$-∞-operad $\mathcal{O}^{\otimes}$, we define categorical patterns $\mathfrak{P}_{\mathcal{O}}$ and $\mathfrak{P}_{\mathcal{O}}^{\otimes}$ on $\mathcal{O}^{\otimes}$ by the construction of [Lur17, Rem. B.1.5]. In other words, let B denote the set of pairs $(\underline{\alpha}, \overline{f_\alpha})$ where $\overline{f_\alpha} : (n^{\lhd})^{\sharp} \longrightarrow (\mathcal{O}^{\otimes}, \mathrm{Ne})$ is any lift of f_α, and let

$$\mathfrak{P}_{\mathcal{O}} = (\mathrm{Ne}, \mathcal{A}ll, \{\overline{f_\alpha} : n^{\lhd} \longrightarrow \mathcal{O}^{\otimes}\}_{(\underline{\alpha}, \overline{f_\alpha}) \in B}),$$
$$\mathfrak{P}_{\mathcal{O}}^{\otimes} = (\mathrm{Ne}, \mathcal{A}ll, \{\overline{f_\alpha} : n^{\lhd} \longrightarrow \mathcal{O}^{\otimes}\}_{(\underline{\alpha}, \overline{f_\alpha}) \in B}).$$

2.6.2. **Theorem-Construction.** The $\mathcal{T}$-*operadic model structure* on the category $\mathbf{sSet}^+_{/(\underline{\mathbf{F}}_{\mathcal{T},*}, \mathrm{Ne})}$ is that defined by the categorical pattern $\mathfrak{P}_{\mathcal{T}}$ of Definition 2.6.1 according to [Lur17, Thm. B.0.20]. The $\mathcal{T}$-operadic model structure is left proper, combinatorial, simplicial, and has the following properties:

(1) The cofibrations are precisely the monomorphisms.
(2) A marked map $X \longrightarrow Y$ over $(\underline{\mathbf{F}}_{\mathcal{T},*}, \mathrm{Ne})$ is a weak equivalence if for any $\mathcal{T}$-∞-operad $\mathcal{O}^{\otimes}$, the induced map
$$\mathrm{Map}_{/(\underline{\mathbf{F}}_{\mathcal{T},*}, \mathrm{Ne})}(Y, (\mathcal{O}^{\otimes}, \mathrm{Ne})) \longrightarrow \mathrm{Map}_{/(\underline{\mathbf{F}}_{\mathcal{T},*}, \mathrm{Ne})}(X, (\mathcal{O}^{\otimes}, \mathrm{Ne}))$$
is a weak equivalence.

(3) An object is fibrant if it is of the form $(\mathcal{O}^{\otimes}, \mathrm{Ne})$ for some $\mathcal{T}$-∞-operad $\mathcal{O}^{\otimes}$.
(4) The fibrations between fibrant objects in $\mathbf{sSet}^+_{/(\underline{\mathbf{F}}_{\mathcal{T},*}, \mathrm{Ne})}$ are exactly given by the fibrations of $\mathcal{T}$-∞-operads.

Furthermore, for any $\mathcal{T}$-∞-operad $\mathcal{O}^{\otimes}$, we define the $\mathcal{T}$-*operadic model structure* on the category $\mathbf{sSet}^+_{/(\mathcal{O}^{\otimes}, \mathrm{Ne})}$ via the categorical pattern $\mathfrak{P}_{\mathcal{O}}$, and this coincides with the model structure induced from the $\mathcal{T}$-operadic model structure on $\mathbf{sSet}^+_{/(\underline{\mathbf{F}}_{\mathcal{T},*}, \mathrm{Ne})}$ by slicing over $(\mathcal{O}^{\otimes}, \mathrm{Ne})$.

Finally, we also define the $\mathcal{T}$-*monoidal model structure* on the category $\mathbf{sSet}^+_{/\mathcal{O}^{\otimes}}$ via the categorical pattern $\mathfrak{P}^{\otimes}_{\mathcal{O}}$. This construction has the same formal properties as with the $\mathcal{T}$-operadic model structure, but where the fibrant objects are precisely the $\mathcal{O}$-monoidal $\mathcal{T}$-∞-categories with the cocartesian edges marked.

Proof. The construction of the $\mathcal{T}$-operadic model structure on $\mathbf{sSet}^+_{/(\underline{\mathbf{F}}_{\mathcal{T},*}, \mathrm{Ne})}$ and the first three claims about it follows immediately from [Lur17, Thm. B.0.20] and the definition of a $\mathcal{T}$-∞-operad. The fourth claim and the assertion about the model structure on $\mathbf{sSet}^+_{/(\mathcal{O}^{\otimes}, \mathrm{Ne})}$ follow from [Lur17, Prop. B.2.7]. Finally, the analogous assertions about the $\mathcal{T}$-monoidal model structure all follow in the same way (cf. [Lur17, Var. 2.1.4.13]). □

2.6.3. **Definition.** We define the ∞-*category of (small)* $\mathcal{T}$-∞-*operads*

$$\mathbf{Op}_{\mathcal{T}} := N((\mathbf{sSet}^+_{/(\underline{\mathbf{F}}_{\mathcal{T},*}, \mathrm{Ne})})^f)$$

to be the simplicial nerve of the full simplicial subcategory of $\mathbf{sSet}^+_{/(\underline{\mathbf{F}}_{\mathcal{T},*}, \mathrm{Ne})}$ spanned by the fibrant objects in the $\mathcal{T}$-operadic model structure. We further let $\mathbf{Cat}^{\otimes}_{\mathcal{T}}$ denote the subcategory of $\mathbf{Op}_{\mathcal{T}}$ spanned by the (small) $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-categories and $\mathcal{T}$-symmetric monoidal functors thereof, or equivalently, the simplicial nerve $N((\mathbf{sSet}^+_{/\underline{\mathbf{F}}_{\mathcal{T},*}})^f)$ taken with respect to the $\mathcal{T}$-monoidal model structure.

For a small $\mathcal{T}$-∞-operad $\mathcal{O}^{\otimes}$, we then let

$$\mathbf{Op}_{\mathcal{O},\mathcal{T}} := N((\mathbf{sSet}^+_{/(\mathcal{O}^{\otimes}, \mathrm{Ne})})^f), \quad \mathbf{Cat}^{\otimes}_{\mathcal{O},\mathcal{T}} := N((\mathbf{sSet}^+_{/\mathcal{O}^{\otimes}})^f).$$

Note that $\mathbf{Op}_{\mathcal{O},\mathcal{T}} \simeq (\mathbf{Op}_{\mathcal{T}})^{/\mathcal{O}^{\otimes}}$ and $\mathbf{Cat}^{\otimes}_{\mathcal{O},\mathcal{T}}$ includes as the subcategory of $\mathbf{Op}_{\mathcal{O},\mathcal{T}}$ on the $\mathcal{O}$-monoidal $\mathcal{T}$-∞-categories and morphisms thereof.

2.6.4. **Corollary.** *For any small* $\mathcal{T}$-∞-*operad* $\mathcal{O}^{\otimes}$*, the* ∞-*categories* $\mathbf{Op}_{\mathcal{O},\mathcal{T}}$ *and* $\mathbf{Cat}^{\otimes}_{\mathcal{O},\mathcal{T}}$ *are presentable.*

Proof. Since the $\mathcal{T}$-operadic model structure on $\mathbf{sSet}^+_{/(\mathcal{O}^{\otimes}, \mathrm{Ne})}$ and the $\mathcal{T}$-monoidal model structure on $\mathbf{sSet}^+_{/\mathcal{O}^{\otimes}}$ are combinatorial and simplicial by Theorem-Construction 2.6.2, it follows from [Lur09, Prop. A.3.7.6] that $\mathbf{Op}_{\mathcal{O},\mathcal{T}}$ and $\mathbf{Cat}^{\otimes}_{\mathcal{O},\mathcal{T}}$ are presentable. □

Using the theory of categorical patterns, it is easy to construct *cotensors* in the ∞-category of $\mathcal{T}$-∞-operads fibered over a given base.

2.6.5. **Construction.** Let $\mathcal{O}^{\otimes}$ be a $\mathcal{T}$-∞-operad and let K be a marked simplicial set. By [Lur17, Prop. B.1.9] applied to the trivial categorical pattern on $\mathbf{sSet}^+$ and $\mathcal{P}_{\mathcal{O}}$ on $\mathbf{sSet}^+_{/(\mathcal{O}^{\otimes}, \mathrm{Ne})}$, the functor

$$(- \times K) : \mathbf{sSet}^+_{/(\mathcal{O}^{\otimes}, \mathrm{Ne})} \longrightarrow \mathbf{sSet}^+_{/(\mathcal{O}^{\otimes}, \mathrm{Ne})}, \quad A \mapsto A \times K$$

is left Quillen. We denote its right adjoint on fibrant objects by $(\mathcal{C}^{\otimes}, p) \mapsto ((\mathcal{C}^{\otimes}, p)^K, p^K)$ and the underlying $\mathcal{T}$-∞-category by $(\mathcal{C}, p)^K$. Since this adjunction is also simplicial, for $(\mathcal{C}^{\otimes}, p)$ and $(\mathcal{D}^{\otimes}, q)$ fibrations of $\mathcal{T}$-∞-operads over $\mathcal{O}^{\otimes}$ we obtain equivalences of ∞-categories

$$\mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, (\mathcal{D}, q)^K) \simeq \mathrm{Fun}_{/(\mathcal{O}^{\otimes}, \mathrm{Ne})}(K \times (\mathcal{C}^{\otimes}, \mathrm{Ne}), (\mathcal{D}^{\otimes}, \mathrm{Ne})) \simeq \mathrm{Fun}(K, \mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{D})^{\sim})$$

where $(-)^{\sim}$ means we take the marking given by the equivalences. In other words, we have constructed the cotensor of $\mathbf{Op}_{\mathcal{O},\mathcal{T}}$ over $\mathbf{Cat}$ at the level of marked simplicial sets. Note also that a fibrant replacement of $K \times (\mathcal{C}^{\otimes}, \mathrm{Ne})$ computes the tensor. Repeating this analysis with the categorical pattern $\mathcal{P}^{\otimes}_{\mathcal{O}}$, we see that if $\mathcal{C}^{\otimes}$ and $\mathcal{D}^{\otimes}$ are $\mathcal{O}$-monoidal, then $(\mathcal{D}^{\otimes}, p)^K$ is moreover $\mathcal{O}$-monoidal, and we have equivalences of ∞-categories

$$\mathrm{Fun}^{\otimes}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, (\mathcal{D}, q)^K) \simeq \mathrm{Fun}_{/\mathcal{O}^{\otimes}}(K \times (\mathcal{C}^{\otimes})^{\sharp}, (\mathcal{D}^{\otimes})^{\sharp}) \simeq \mathrm{Fun}(K, \mathrm{Fun}^{\otimes}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{D})^{\sim}).$$

Moreover, note that if $F : \mathcal{O} \longrightarrow \mathbf{Cat}$ denotes the functor classifying $\mathcal{D} \longrightarrow \mathcal{O}$, then $(\mathcal{D}, q)^K \longrightarrow \mathcal{O}$ is classified by the functor $\mathcal{O} \longrightarrow \mathbf{Cat}$ given by applying $\mathrm{Fun}(K, (-)^{\sim})$ fiberwise to F. We may thus consider $(\mathcal{D}^{\otimes}, p)^K$ to be a construction of the *pointwise* $\mathcal{O}$-monoidal structure on $(\mathcal{D}, q)^K$.

2.7. **Big $\mathcal{T}$-∞-operads.** For certain arguments, it is technically inconvenient that the base $\mathcal{T}$ does not admit pullbacks. We will thus need to consider an equivalent definition of a $\mathcal{T}$-∞-operad.

2.7.1. **Definition.** Let $\mathrm{Ar}(\mathbf{F}_{\mathcal{T}})^{tdeg}, \mathrm{Ar}(\mathbf{F}_{\mathcal{T}})^{si}$ denote the wide subcategories of $\mathrm{Ar}(\mathbf{F}_{\mathcal{T}})$ on morphisms

$$\sigma = \begin{pmatrix} U & \longrightarrow & X \\ \big\downarrow & & \big\downarrow \\ V & \longrightarrow & Y \end{pmatrix}$$

such that $\mathrm{ev}_1(\sigma) : V \longrightarrow Y$ is a degenerate edge, resp. the induced morphism $U \longrightarrow V \times_Y X$ is a summand inclusion. Then $(\mathrm{Ar}(\mathbf{F}_{\mathcal{T}}); \mathrm{Ar}(\mathbf{F}_{\mathcal{T}})^{si}, \mathrm{Ar}(\mathbf{F}_{\mathcal{T}})^{tdeg})$ is a disjunctive triple, and we define

$$\underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*} := \mathrm{Span}(\mathrm{Ar}(\mathbf{F}_{\mathcal{T}}); \mathrm{Ar}(\mathbf{F}_{\mathcal{T}})^{si}, \mathrm{Ar}(\mathbf{F}_{\mathcal{T}})^{tdeg}).$$

Evaluation at the target defines a structure map $\underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*} \longrightarrow \mathbf{F}^{\mathrm{op}}_{\mathcal{T}}$, which is a cocartesian fibration.

2.7.2. **Definition.** We define a categorical pattern $\widetilde{\mathfrak{P}}_{\mathcal{T}}$ on $\underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*}$ as follows. Let $\phi : U \longrightarrow V$ be a morphism in $\mathbf{F}_{\mathcal{T}}$ and $\Sigma = \{\sigma_1, ..., \sigma_n\}$ be a collection of commutative squares in $\mathbf{F}_{\mathcal{T}}$

$$\sigma_i = \begin{pmatrix} U_i & \xrightarrow{\alpha_i} & U \\ \big\downarrow{\scriptstyle \phi_i} & & \big\downarrow{\scriptstyle \phi} \\ V_i & \xrightarrow{\beta_i} & V \end{pmatrix}$$

such that α_i is a summand inclusion and the induced map $U_i \longrightarrow V_i \times_V U$ is also a summand inclusion. Let $\chi_{\sigma_i} : \Delta^1 \longrightarrow (\mathrm{Ar}(\mathbf{F}_{\mathcal{T}})^{si})^{\mathrm{op}} \subset \underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*}$ be the morphism corresponding to σ_i.

Suppose moreover that the summand inclusions α_i combine to yield an equivalence $\coprod_{1 \leq i \leq n} U_i \simeq U$. Let

$$f_{\phi,\Sigma} : n^{\lhd} \longrightarrow \underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*}$$

denote the functor which selects the n morphisms χ_{σ_1}, ..., χ_{σ_n}. We then let

$$\widetilde{\mathfrak{P}}_{\mathcal{T}} = (\mathrm{Ne}, \mathcal{A}ll, \{f_{\phi,\Sigma}\})$$

where ϕ and Σ range over all possible choices.

2.7.3. **Definition.** The $\mathcal{T}$-*operadic model structure* on the category $\mathbf{sSet}^+_{/(\underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*}, \mathrm{Ne})}$ is that defined by the categorical pattern $\widetilde{\mathfrak{P}}_{\mathcal{T}}$ of Definition 2.7.2 according to [Lur17, Thm. B.0.20]. We call the fibrant objects *big* $\mathcal{T}$-∞-*operads*.

For any big $\mathcal{T}$-∞-operad $\widetilde{\mathcal{O}}^{\otimes} \longrightarrow \underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*}$, we then define the $\mathcal{T}$-*operadic model structure* on $\mathbf{sSet}^+_{/(\widetilde{\mathcal{O}}^{\otimes}, \mathrm{Ne})}$ via the categorical pattern

$$\widetilde{\mathfrak{P}}_{\mathcal{O}} = (\mathrm{Ne}, \mathcal{A}ll, \{f_{x,\phi,\Sigma}\}),$$

where the $f_{x,\phi,\Sigma} : n^{\lhd} \longrightarrow \widetilde{\mathcal{O}}^{\otimes}$ range over all cocartesian sections of the $f_{\phi,\Sigma}$, and the x in the notation denotes the value of $f_{x,\phi,\Sigma}$ on the cone point v.

Given a big $\mathcal{T}$-∞-operad $\widetilde{\mathcal{O}}^{\otimes} \longrightarrow \underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*} \longrightarrow \mathbf{F}^{\mathrm{op}}_{\mathcal{T}}$, we will let $\mathcal{O}^{\otimes} \longrightarrow \underline{\mathbf{F}}_{\mathcal{T},*} \longrightarrow \mathcal{T}^{\mathrm{op}}$ denote its pullback along the inclusion $\mathcal{T}^{\mathrm{op}} \subset \mathbf{F}^{\mathrm{op}}_{\mathcal{T}}$. Clearly, $\mathcal{O}^{\otimes}$ is a $\mathcal{T}$-∞-operad.

2.7.4. **Proposition.** *Let $\widetilde{\mathcal{O}}^{\otimes}$ be a big $\mathcal{T}$-∞-operad over $\underline{\mathbf{F}}^{big}_{\mathcal{T},*}$ and consider the span*

$$(\widetilde{\mathcal{O}}^{\otimes}, \mathrm{Ne}) \xleftarrow{\mathrm{ev}_0} (\mathrm{Ar}^{ne}(\widetilde{\mathcal{O}}^{\otimes}) \times_{\widetilde{\mathcal{O}}^{\otimes}} O^{\otimes}, \mathrm{Ne}) \xrightarrow{\mathrm{pr}_{\mathcal{O}^{\otimes}}} (\mathcal{O}^{\otimes}, \mathrm{Ne}).$$

Then the adjunction

$$(\mathrm{pr}_{\mathcal{O}^{\otimes}})_!(\mathrm{ev}_0)^* : \mathbf{sSet}^+_{/(\widetilde{\mathcal{O}}^{\otimes}, \mathrm{Ne})} \rightleftarrows \mathbf{sSet}^+_{/(\mathcal{O}^{\otimes}, \mathrm{Ne})} : (\mathrm{ev}_0)_*(\mathrm{pr}_{\mathcal{O}^{\otimes}})^*$$

is a Quillen equivalence.

Proof. We first show that $(\mathrm{pr}_{\mathcal{O}^\otimes})_!(\mathrm{ev}_0)^* \dashv (\mathrm{ev}_0)_*(\mathrm{pr}_{\mathcal{O}^\otimes})^*$ is a Quillen adjunction. For this, it suffices to show that $(\mathrm{ev}_0)_*(\mathrm{pr}_{\mathcal{O}^\otimes})^*$ preserves fibrant objects. Examining the proof of [Sha21b, Prop. 3.5(1)], we see that it implies

$$\mathrm{ev}_0 : \mathrm{Ar}^{ne}(\widetilde{\mathcal{O}}^\otimes) \times_{\widetilde{\mathcal{O}}^\otimes} \mathcal{O}^\otimes \longrightarrow \widetilde{\mathcal{O}}^\otimes$$

is a cartesian fibration, because any fiberwise active edge with target in $\mathcal{O}^\otimes$ necessarily has source in $\mathcal{O}^\otimes$. Therefore, the hypotheses of [Lur17, Thm. B.4.2] are satisfied *excluding those involving the maps* $f_{x,\phi,\Sigma}$. We deduce that $(\mathrm{ev}_0)_*(\mathrm{pr}_{\mathcal{O}^\otimes})^*$ sends fibrant objects to fibrations over $\widetilde{\mathcal{O}}^\otimes$ which are cocartesian over the inert edges. Given a $\mathcal{T}$-∞-operad $\mathcal{C}^\otimes$, let $\widetilde{\mathcal{C}}^\otimes = (\mathrm{ev}_0)_*(\mathrm{pr}_{\mathcal{O}^\otimes})^*(\mathcal{C}^\otimes)$. It remains to show that for every $f_{x,\phi,\Sigma} : n^\lhd \longrightarrow \widetilde{\mathcal{O}}^\otimes$,

(i) the functor $n^\lhd \longrightarrow \mathbf{Cat}$ classifying the cocartesian fibration $n^\lhd \times_{\widetilde{\mathcal{O}}^\otimes} \widetilde{\mathcal{C}}^\otimes$ is a limit diagram.
(ii) For every cocartesian section $n^\lhd \longrightarrow n^\lhd \times_{\widetilde{\mathcal{O}}^\otimes} \widetilde{\mathcal{C}}^\otimes$, the composite $n^\lhd \longrightarrow \widetilde{\mathcal{C}}^\otimes$ is a f-limit diagram for $f : \widetilde{\mathcal{C}}^\otimes \longrightarrow \widetilde{\mathcal{O}}^\otimes$.

In fact, we only need to consider $f_{x,\phi,\Sigma}$ where Σ is given by squares

$$\begin{array}{ccc} U_i & \longrightarrow & U \\ \downarrow{\scriptstyle =} & & \downarrow{\scriptstyle \phi} \\ U_i & \longrightarrow & V \end{array}$$

with U_i an orbit, so we will suppose this in the remainder of the argument.

For (i), recall from [Sha21a, Ex. 2.26] that the right Kan extension of a functor $\mathcal{C} \longrightarrow \mathbf{Cat}$ along $\mathcal{C} \longrightarrow \mathcal{D}$ is modeled at the level of cocartesian fibrations by the push-pull construction involving the span

$$\mathcal{D} \longleftarrow \mathrm{Ar}(\mathcal{D}) \times_{\mathcal{D}} \mathcal{C} \longrightarrow \mathcal{C}.$$

Therefore, $\widetilde{\mathcal{C}}^\otimes_{ne}$ is the right Kan extension of $\mathcal{C}^\otimes_{ne}$ along $\mathcal{O}^\otimes_{ne} \subset \widetilde{\mathcal{O}}^\otimes_{ne}$. In particular, given $x \in \widetilde{\mathcal{O}}^\otimes$ over $[f_+ : U_+ \to V] \in \underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*}$ and an orbit decomposition $V \simeq V_1 \coprod ... \coprod V_m$, let $x \longrightarrow x_j$ be inert morphisms lifting the cocartesian morphisms $[U_+ \to V] \longrightarrow [(U \times_V V_j)_+ \times V_j]$. Then we have an equivalence $\widetilde{\mathcal{C}}^\otimes_x \simeq \prod_{1 \leq j \leq m} \mathcal{C}^\otimes_{x_j}$, and postcomposing with the further decompositions of $\mathcal{C}^\otimes_{x_j}$ given by orbit decompositions of $U \times_V V_j$ verifies (i).

For (ii), it suffices to prove that for every fiberwise active edge $\alpha : x \longrightarrow y \in \widetilde{\mathcal{O}}^\otimes$ over $[U'_+ \to V] \longrightarrow [U_+ \to V]$, objects $\overline{x}, \overline{y} \in \widetilde{\mathcal{C}}^\otimes$ over x, y, and identification $\overline{y} \simeq (\overline{y}_1, ..., \overline{y}_n)$ induced by $f_{y,\phi,\Sigma}$,

$$\mathrm{Map}^\alpha_{\widetilde{\mathcal{C}}^\otimes}(\overline{x}, \overline{y}) \simeq \prod_{1 \leq i \leq n} \mathrm{Map}^{\alpha_i}_{\widetilde{\mathcal{C}}^\otimes}(\overline{x}, \overline{y}_i).$$

where α_i is the composition $x \longrightarrow y \longrightarrow y_i$.

However, for an orbit decomposition $V \simeq V_1 \coprod ... \coprod V_m$ and corresponding inert morphisms $\overline{x} \longrightarrow \overline{x}_j$, $\overline{y} \longrightarrow \overline{y}_j$, we have that

$$\mathrm{Map}^\alpha_{\widetilde{\mathcal{C}}^\otimes}(\overline{x}, \overline{y}) \simeq \prod_{1 \leq j \leq m} \mathrm{Map}^{\alpha^j}_{C^\otimes}(\overline{x}_j, \overline{y}_j)$$

where $\alpha \simeq (\alpha^j : x_j \longrightarrow y_j)$ under the same decomposition for mapping spaces in $\widetilde{\mathcal{O}}^\otimes$. Using the known decompositions of mapping spaces in $\mathcal{C}^\otimes$ then yields the claim.

Finally, it is easy to see that the induced adjunction of ∞-categories

$$(\mathbf{Op}^{\mathrm{big}}_{\mathcal{T}})_{/\widetilde{\mathcal{O}}^\otimes} \rightleftarrows (\mathbf{Op}_{\mathcal{T}})_{/\mathcal{O}^\otimes}$$

is an equivalence because the unit and counit transformations are equivalences. Hence the Quillen adjunction is a Quillen equivalence. ☐

2.7.5. **Corollary.** *Let $\widetilde{\mathcal{O}}^\otimes$ be a big $\mathcal{T}$-∞-operad over $\underline{\mathbf{F}}^{big}_{\mathcal{T},*}$ and let $i : \mathcal{O}^\otimes \longrightarrow \widetilde{\mathcal{O}}^\otimes$ denote the inclusion. Then we have a Quillen equivalence*

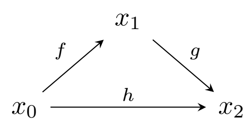
$$i_! : \mathbf{sSet}^+_{/(\mathcal{O}^\otimes, \mathrm{Ne})} \rightleftarrows \mathbf{sSet}^+_{/(\widetilde{\mathcal{O}}^\otimes, \mathrm{Ne})} : i^*$$

Proof. i is obviously compatible with the categorical patterns defining the model structures in the sense of [Lur17, B.2.8], so $i_! \dashv i^*$ is a Quillen adjunction. Moreover, at the level of the underlying ∞-categories i^* is left adjoint to the right Quillen functor of Proposition 2.7.4. Hence the Quillen adjunction is a Quillen equivalence. ☐

2.8. **Monoidal envelopes.** In this subsection, we apply the theory of parametrized factorization systems [Sha21b, §3] to construct the $\mathcal{O}$-monoidal envelope of any fibration of $\mathcal{T}$-∞-operads $\mathcal{C}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$. First recall the notion of $\mathcal{T}$-factorization system from [Sha21b, Def. 3.1] and the associated 'total' factorization system of [Sha21b, Def. 3.2].

2.8.1. **Example.** We have the inert-active $\mathcal{T}$-factorization system on $\underline{\mathbf{F}}_{\mathcal{T},*}$ given fiberwise by the inert-active factorization system on $\mathbf{F}_{\mathcal{T}^{/V},*}$ as in Remark 2.1.5. Note that the definition of (possibly non-fiberwise) inert and active edges in $\underline{\mathbf{F}}_{\mathcal{T},*}$ given initially in Definition 2.1.3 then matches that of [Sha21b, Def. 3.2]. More generally, we have the inert-active $\mathcal{T}$-factorization system on any $\mathcal{T}$-∞-operad $\mathcal{O}^{\otimes}$. From this, we obtain the inert-fiberwise active factorization system on $\mathcal{O}^{\otimes}$ itself.

2.8.2. **Remark.** The inert edges in $\underline{\mathbf{F}}_{\mathcal{T},*}$ and $\underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*}$ satisfy the following right cancellation property: if we have a 2-simplex



such that f is inert, then g is inert if and only if h is inert. The 'only if' direction is clear. To see the converse, note that by factoring f as a cocartesian edge followed by a fiberwise inert edge, we may suppose that f is of either form. Then by examining the composition of spans, we see that the claimed assertion reduces to the two-out-of-three property for equivalences in $(\mathbf{F}_{\mathcal{T}})^{/U}$, where x_2 lies over U.

In contrast, the active edges *do not* satisfy the left cancellation property, because cocartesian edges do not. However, fiberwise active edges *do* satisfy the left cancellation property, just as they do in the theory of ∞-operads.

2.8.3. **Notation.** Given a $\mathcal{T}$-∞-operad $\mathcal{O}^{\otimes}$, let $\mathrm{Ar}^{act}(\mathcal{O}^{\otimes})$ denote the full $\mathcal{T}$-subcategory of $\mathrm{Ar}(\mathcal{O}^{\otimes})$ on the active morphisms, and let

$$\mathrm{Ar}^{act}_{\mathcal{T}}(\mathcal{O}^{\otimes}) = \mathcal{T}^{\mathrm{op}} \times_{\mathrm{Ar}(\mathcal{T}^{\mathrm{op}})} \mathrm{Ar}^{act}(\mathcal{O}^{\otimes}).$$

2.8.4. **Definition.** Given a fibration of $\mathcal{T}$-∞-operads $p : \mathcal{C}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$, the $\mathcal{O}$-*monoidal envelope* of p is

$$\mathrm{Env}_{\mathcal{O},\mathcal{T}}(\mathcal{C})^{\otimes} := \mathcal{C}^{\otimes} \times_{\mathcal{O}^{\otimes}} \mathrm{Ar}^{act}_{\mathcal{T}}(\mathcal{O}^{\otimes}) \longrightarrow \mathcal{O}^{\otimes}.$$

If $\mathcal{O}^{\otimes} = \underline{\mathbf{F}}_{\mathcal{T},*}$, we will abbreviate $\mathrm{Env}_{\mathcal{O},\mathcal{T}}(\mathcal{C})^{\otimes}$ as $\mathrm{Env}_{\mathcal{T}}(\mathcal{C})^{\otimes}$ and refer to it as the $\mathcal{T}$-*symmetric monoidal envelope* of $\mathcal{C}^{\otimes}$.

2.8.5. **Remark.** For a $\mathcal{T}$-∞-operad $\mathcal{C}^{\otimes}$, the underlying $\mathcal{T}$-∞-category of $\mathrm{Env}_{\mathcal{T}}(\mathcal{C})^{\otimes}$ is $\mathcal{C}^{\otimes}_{act}$.

2.8.6. **Proposition.** *Let $p : \mathcal{C}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ be a fibration of $\mathcal{T}$-∞-operads. Then $\mathrm{Env}_{\mathcal{O},\mathcal{T}}(\mathcal{C})^{\otimes}$ is a $\mathcal{O}$-monoidal $\mathcal{T}$-∞-category.*

Proof. We need to show that

$$\mathrm{ev}_1 : \mathcal{C}^{\otimes} \times_{\mathcal{O}^{\otimes}} \mathrm{Ar}^{act}_{\mathcal{T}}(\mathcal{O}^{\otimes}) \longrightarrow \mathcal{O}^{\otimes}$$

is a cocartesian fibration of $\mathcal{T}$-∞-operads. By [Sha21b, Prop. 3.5(2)], ev_1 is a cocartesian fibration. We now seek to verify the criterion of Proposition 2.2.6 to finish the proof. Because $\mathcal{O}^{\otimes}$ is a $\mathcal{T}$-∞-operad, for any object $y \in \mathcal{O}^{\otimes}_{[U_+ \to V]}$, orbit decomposition $U \simeq U_1 \coprod ... \coprod U_n$, and inert edges $\rho^i : y \longrightarrow y_i$ lifting the characteristic morphisms $\chi_{[U_i \subset U]}$, the ρ^i induce an equivalence

$$((\mathcal{O}^{\otimes}_{act})_V)^{/y} \simeq \prod_{1 \leq i \leq n} ((\mathcal{O}^{\otimes}_{act})_{U_i})^{/y_i}.$$

Using that $\mathcal{C}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ is a fibration of $\mathcal{T}$-∞-operads, we have the further equivalence

$$(\mathcal{C}^{\otimes}_{act})_V \times_{(\mathcal{O}^{\otimes}_{act})_V} ((\mathcal{O}^{\otimes}_{act})_V)^{/y} \simeq \prod_{1 \leq i \leq n} (\mathcal{C}^{\otimes}_{act})_{U_i} \times_{(\mathcal{O}^{\otimes}_{act})_{U_i}} ((\mathcal{O}^{\otimes}_{act})_{U_i})^{/y_i}.$$

Using that the fiberwise active edges are left cancellative, we identify the lefthand side with $(\mathcal{C}^{\otimes} \times_{\mathcal{O}^{\otimes}} \mathrm{Ar}^{act}_{\mathcal{T}}(\mathcal{O}^{\otimes}))_y$, and similarly for the righthand side. The stated equivalence is then the one induced by the Segal maps, and we conclude that $\mathrm{ev}_1 : \mathcal{C}^{\otimes} \times_{\mathcal{O}^{\otimes}} \mathrm{Ar}^{act}_{\mathcal{T}}(\mathcal{O}^{\otimes}) \longrightarrow \mathcal{O}^{\otimes}$ is a cocartesian fibration of $\mathcal{T}$-∞-operads. □

2.8.7. **Proposition.** *Let $p : \mathcal{C}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ be a fibration of $\mathcal{T}$-∞-operads and let $q : \mathcal{D}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ be a cocartesian fibration of $\mathcal{T}$-∞-operads. Let $i : \mathcal{C}^{\otimes} \subset \mathrm{Env}_{\mathcal{O},\mathcal{T}}(\mathcal{C})^{\otimes}$ denote the inclusion of $\mathcal{C}^{\otimes}$ into its $\mathcal{O}$-monoidal envelope.*

(1) Precomposition by i yields an equivalence

$$i^* : \mathrm{Fun}^{\otimes}_{\mathcal{O},\mathcal{T}}(\mathrm{Env}_{\mathcal{O},\mathcal{T}}(\mathcal{C}), \mathcal{D}) \longrightarrow \mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{D}).$$

(2) We have an adjunction

$$i_! : \mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{D}) \rightleftarrows \mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathrm{Env}_{\mathcal{O},\mathcal{T}}(\mathcal{C}), \mathcal{D}) : i^*$$

where $i_!$ is the fully faithful inclusion of $\mathrm{Fun}^{\otimes}_{\mathcal{O},\mathcal{T}}(\mathrm{Env}_{\mathcal{O},\mathcal{T}}(\mathcal{C}), \mathcal{D})$ under the equivalence of (1).

Proof. This follows immediately from [Sha21b, Thm. 3.6], using the inert-active $\mathcal{T}$-factorization system on $\mathcal{O}^{\otimes}$. □

2.8.8. **Corollary.** *Let $\mathcal{O}^{\otimes}$ be a $\mathcal{T}$-∞-operad. We have an adjunction*

$$\mathrm{Env}^{\otimes}_{\mathcal{O},\mathcal{T}} : \mathbf{Op}_{\mathcal{O},\mathcal{T}} \rightleftarrows \mathbf{Cat}^{\otimes}_{\mathcal{O},\mathcal{T}} : \mathrm{U}.$$

2.9. **Subcategories and localization.** Let $\mathcal{C}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ be a fibration of $\mathcal{T}$-∞-operads. Given a full $\mathcal{T}$-subcategory $\mathcal{D} \subset \mathcal{C}$, let $\mathcal{D}^{\otimes}$ be the full $\mathcal{T}$-subcategory of $\mathcal{C}^{\otimes}$ on the objects of $\mathcal{D}$ (using the Segal decompositions of the fibers of $\mathcal{C}^{\otimes}$). Clearly, $\mathcal{D}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ is a fibration of $\mathcal{T}$-∞-operads, and the inclusion $\mathcal{D}^{\otimes} \longrightarrow \mathcal{C}^{\otimes}$ is a morphism of $\mathcal{T}$-∞-operads over $\mathcal{O}^{\otimes}$. In this subsection, we state conditions under which $\mathcal{D}^{\otimes}$ inherits an $\mathcal{O}$-monoidal structure from $\mathcal{C}^{\otimes}$. Our presentation of these results parallels and extends those of [Lur17, §2.2.1].

2.9.1. **Proposition.** *Let $\mathcal{C}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ be a fibration of $\mathcal{T}$-∞-operads and let $\mathcal{D} \subset \mathcal{C}$ be a full $\mathcal{T}$-subcategory. Suppose that for every fiberwise active edge $\alpha : x \longrightarrow y$ in $\mathcal{O}^{\otimes}_V$ with $y \in \mathcal{O}_V$, the pushforward functor $\otimes_{\alpha} : \mathcal{C}^{\otimes}_x \longrightarrow \mathcal{C}_y$ restricts to a functor $\mathcal{D}^{\otimes}_x \longrightarrow \mathcal{D}_y$. Then $\mathcal{D}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ is a cocartesian fibration and the inclusion $\mathcal{D}^{\otimes} \longrightarrow \mathcal{C}^{\otimes}$ is an $\mathcal{O}$-monoidal $\mathcal{T}$-functor.*

Proof. This is immediate in light of the inert-fiberwise active factorization system on $\mathcal{C}^{\otimes}$ (Example 2.8.1). □

We say that a $\mathcal{T}$-functor $L : \mathcal{C} \longrightarrow \mathcal{C}$ is a *$\mathcal{T}$-localization* if for every object $V \in \mathcal{T}$, L_V is a localization functor. If we let $\mathcal{D}$ denote the essential image of L, then by [Lur17, 7.3.2.6] we have a $\mathcal{T}$-adjunction

$$L : \mathcal{C} \rightleftarrows \mathcal{D} : R$$

where $R : \mathcal{D} \longrightarrow \mathcal{C}$ is the inclusion. Given a $\mathcal{T}$-localization $L : \mathcal{C} \longrightarrow \mathcal{C}$, a morphism in $\mathcal{C}$ is an *L-equivalence* if it lies in a fiber $\mathcal{C}_V$ and is a L_V-equivalence. Similarly, given a $\mathcal{T}$-∞-operad $\mathcal{C}^{\otimes}$, a morphism in $\mathcal{C}^{\otimes}$ is an *L-equivalence* if it lies entirely in a fiber $\mathcal{C}^{\otimes}_{[U_+ \to V]}$ and is a product of L-equivalences under the Segal decomposition of that fiber.

2.9.2. **Theorem.** *Let $\mathcal{O}^{\otimes}$ be a $\mathcal{T}$-∞-operad and $\mathcal{C}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ an $\mathcal{O}$-monoidal $\mathcal{T}$-∞-category. Let $L : \mathcal{C} \longrightarrow \mathcal{C}$ be a $\mathcal{T}$-localization and let $\mathcal{D} \subset \mathcal{C}$ be its essential image. Suppose that for every fiberwise active edge $\alpha : x \longrightarrow y \in \mathcal{O}^{\otimes}_V$ with $y \in \mathcal{O}_V$, the pushforward functor $\otimes_{\alpha} : \mathcal{C}^{\otimes}_x \longrightarrow \mathcal{C}_y$ preserves L-equivalences. Then we have a relative adjunction over $\mathcal{O}^{\otimes}$*

$$L^{\otimes} : \mathcal{C}^{\otimes} \rightleftarrows \mathcal{D}^{\otimes} : R^{\otimes}$$

with $L^{\otimes}$ an $\mathcal{O}$-monoidal functor (i.e., preserving cocartesian edges over $\mathcal{O}^{\otimes}$) and $R^{\otimes}$ a lax $\mathcal{O}$-monoidal functor (i.e., a morphism of T-∞-operads), which prolongs the $\mathcal{T}$-adjunction $L : \mathcal{C} \rightleftarrows \mathcal{D} : R$.

Proof. This is immediate from the inert-fiberwise active factorization system on $\mathcal{C}^{\otimes}$ (Example 2.8.1) together with the criterion of [BH21, Prop. D.7]. □

2.9.3. **Remark.** In the case where $\mathcal{O}^{\otimes} = \underline{\mathbf{F}}_{\mathcal{T},*}$, the criterion of Theorem 2.9.2 amounts to

(1) For every object $V \in \mathcal{T}$ and $Z \in \mathcal{C}_V$, the functor

$$- \otimes Z : \mathcal{C}_V \longrightarrow \mathcal{C}_V$$

preserves L_V-equivalences.

(2) For every morphism $f : V \longrightarrow W$ in $\mathcal{T}$, the norm functor
$$f_\otimes : \mathcal{C}_V \longrightarrow \mathcal{C}_W$$
sends L_V-equivalences to L_W-equivalences.

3. Parametrized Day convolution

In this section, we construct a (partially-defined) internal hom for $\mathcal{T}$-∞-operads fibered over an arbitrary base $\mathcal{T}$-∞-operad $\mathcal{O}^\otimes$: the *$\mathcal{T}$-Day convolution*. We first introduce the notion of an *$\mathcal{O}$-promonoidal $\mathcal{T}$-∞-category* $\mathcal{C}^\otimes$, which is the analogue of a flat categorical fibration[11] in the context of $\mathcal{T}$-∞-operads. The $\mathcal{O}$-promonoidal condition ensures the existence of the *p-operadic coinduction* functor (Corollary 3.1.5), and given a $\mathcal{O}$-promonoidal $\mathcal{T}$-∞-category $p : \mathcal{C}^\otimes \longrightarrow \mathcal{O}^\otimes$ and any fibration $\mathcal{E}^\otimes \longrightarrow \mathcal{O}^\otimes$ of $\mathcal{T}$-∞-operads, we may then use the p-operadic coinduction on the pullback of $\mathcal{E}^\otimes$ over $\mathcal{C}^\otimes$ to construct the *$\mathcal{T}$-Day convolution* (Definition 3.1.6)
$$\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C},\mathcal{E})^\otimes \longrightarrow \mathcal{O}^\otimes.$$

We then state conditions on $\mathcal{E}^\otimes$ under which $\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C},\mathcal{E})^\otimes$ is $\mathcal{O}$-monoidal – these amount to the existence of certain $\mathcal{T}$-colimits as well as $\mathcal{T}$-distributivity of the tensor product (Theorem 3.2.6).

3.1. $\mathcal{O}$-promonoidal $\mathcal{T}$-∞-categories and $\mathcal{T}$-Day convolution.

3.1.1. **Definition.** Let $p : \mathcal{C}^\otimes \longrightarrow \mathcal{O}^\otimes$ be a fibration of $\mathcal{T}$-∞-operads. We say that $\mathcal{C}^\otimes$ is *$\mathcal{O}$-promonoidal* if for every $V \in \mathcal{T}$, the functor $p_V : (\mathcal{C}^\otimes_V)_{act} \longrightarrow (\mathcal{O}^\otimes_V)_{act}$ is a flat categorical fibration.

3.1.2. **Example.** Suppose $(\mathcal{C}^\otimes, p)$ is a $\mathcal{O}$-monoidal $\mathcal{T}$-∞-category, so that p is a cocartesian fibration. $\mathcal{C}^\otimes$ is then $\mathcal{O}$-promonoidal since cocartesian fibrations are flat [Lur17, Ex. B.3.4].

3.1.3. **Remark.** To understand the relevance of the $\mathcal{O}$-promonoidal condition, the reader may find it useful to first review the nonparametrized story from [Sha21b, §10]. To our knowledge, the correct definition of an $\mathcal{O}$-promonoidal ∞-category first appeared in Hinich's work [Hin20] (and was misstated in [BGS20]).

For technical reasons, to construct the $\mathcal{T}$-Day convolution we will first work in the setting of big $\mathcal{T}$-∞-operads (i.e., so that the base is $\mathbf{F}^{\mathrm{op}}_{\mathcal{T}}$ in place of $\mathcal{T}^{\mathrm{op}}$). Let $\mathrm{Ar}^{ne}(\widetilde{\mathcal{O}}^\otimes)$ be notation for the full subcategory of $\mathrm{Ar}(\widetilde{\mathcal{O}}^\otimes)$ on the inert edges.

3.1.4. **Theorem.** *Let $\widetilde{\mathcal{O}}^\otimes$ and $\widetilde{\mathcal{C}}^\otimes$ be big $\mathcal{T}$-∞-operads over $\underline{\mathbf{F}}^{big}_{\mathcal{T},*}$ and let $p : \widetilde{\mathcal{C}}^\otimes \longrightarrow \widetilde{\mathcal{O}}^\otimes$ be a fibration of big $\mathcal{T}$-∞-operads such that the restriction $p' : \mathcal{C}^\otimes \longrightarrow \mathcal{O}^\otimes$ is $\mathcal{O}$-promonoidal. Consider the span of marked simplicial sets*
$$(\widetilde{\mathcal{O}}^\otimes, \mathrm{Ne}) \xleftarrow{\mathrm{ev}_0} (\mathrm{Ar}^{ne}(\widetilde{\mathcal{O}}^\otimes) \times_{\widetilde{\mathcal{O}}^\otimes} \widetilde{\mathcal{C}}^\otimes, \mathrm{Ne}) \xrightarrow{\mathrm{pr}_{\widetilde{\mathcal{C}}^\otimes}} (\widetilde{\mathcal{C}}^\otimes, \mathrm{Ne})$$
where by the middle marking Ne *we mean those edges in* $\mathrm{Ar}^{ne}(\widetilde{\mathcal{O}}^\otimes) \times_{\widetilde{\mathcal{O}}^\otimes} \widetilde{\mathcal{C}}^\otimes$ *whose source in $\widetilde{\mathcal{O}}^\otimes$ is inert and whose projection to $\widetilde{\mathcal{C}}^\otimes$ is inert. Then the functor*
$$(\mathrm{ev}_0)_* \circ (\mathrm{pr}_{\widetilde{\mathcal{C}}^\otimes})^* : \mathbf{sSet}^+_{/(\widetilde{\mathcal{C}}^\otimes,\mathrm{Ne})} \longrightarrow \mathbf{sSet}^+_{/(\widetilde{\mathcal{O}}^\otimes,\mathrm{Ne})}$$
is right Quillen with respect to the $\mathcal{T}$-operadic model structures of Definition 2.7.3.

Proof. We verify the hypotheses of [Lur17, Thm. B.4.2].

(1) ev_0 is flat by [Sha21b, Lem. 10.1] applied to the inert-fiberwise active factorization system on $\widetilde{\mathcal{O}}^\otimes$ (Example 2.8.1), noting that products of flat fibrations are flat in order to promote the flatness condition on $(p')_{f.act}$ to $p_{f.act}$.
(2) It is obvious that inert edges are closed under composition and contain the equivalences.
(3) Vacuously true since the categorical patterns we are looking at contain all 2-simplices.

[11] Some authors also call this an exponentiable fibration to highlight its key property: a categorical fibration $\pi : \mathcal{C} \longrightarrow \mathcal{D}$ is said to be *flat* if the right adjoint π_* to the pullback functor $\pi^* : \mathbf{Cat}_{/\mathcal{D}} \longrightarrow \mathbf{Cat}_{/\mathcal{C}}$ exists.

(4) Suppose $e : x_0 \to y_0$ is an inert edge in $\widetilde{\mathcal{O}}^{\otimes}$. Then as we saw in [Sha21b, Prop. 3.5(1)], given an inert edge $y_0 \to y_1$ the cartesian lift of e to an edge $e' : [x_0 \to x_1] \to [y_0 \to y_1]$ in $\mathrm{Ar}^{ne}(\widetilde{\mathcal{O}}^{\otimes})$ has $\mathrm{ev}_1(e') : x_1 \to y_1$ an equivalence. It follows that given a further lift of $y_0 \to y_1$ to an object $(y_0 \to y_1, c \in \widetilde{\mathcal{C}}^{\otimes}_{y_1})$ in $\mathrm{Ar}^{ne}(\widetilde{\mathcal{O}}^{\otimes}) \times_{\widetilde{\mathcal{O}}^{\otimes}} \widetilde{\mathcal{C}}^{\otimes}$, e admits a cartesian lift to an edge $e'' : (x_0 \to x_1, c') \to (y_0 \to y_1, c)$ (with $c' \to c$ an equivalence).

(5) Let $f_{x,\phi,\Sigma} : n^{\lhd} \longrightarrow \widetilde{\mathcal{O}}^{\otimes}$ be in the categorical pattern defining the $\mathcal{T}$-operadic model structure on $\mathbf{sSet}^{+}_{/(\widetilde{\mathcal{O}}^{\otimes},\mathrm{Ne})}$. We claim that the pullback

$$\pi : n^{\lhd} \times_{\widetilde{\mathcal{O}}^{\otimes}} \mathrm{Ar}^{ne}(\widetilde{\mathcal{O}}^{\otimes}) \times_{\widetilde{\mathcal{O}}^{\otimes}} \widetilde{\mathcal{C}}^{\otimes} \longrightarrow n^{\lhd}$$

is a cocartesian fibration. Because inert edges are right cancellative (Remark 2.8.2) and $\widetilde{\mathcal{C}}^{\otimes}$ is cocartesian over the inert edges of $\widetilde{\mathcal{O}}^{\otimes}$, it suffices to show that

$$n^{\lhd} \times_{\widetilde{\mathcal{O}}^{\otimes}_{ne}} \mathrm{Ar}(\widetilde{\mathcal{O}}^{\otimes}_{ne}) \longrightarrow n^{\lhd}$$

is cocartesian, where $\widetilde{\mathcal{O}}^{\otimes}_{ne} \subset \widetilde{\mathcal{O}}^{\otimes}$ is the wide subcategory with morphisms restricted to the inert edges. In fact, we will prove the stronger assertion that

$$\mathrm{ev}_0 : \mathrm{Ar}(\widetilde{\mathcal{O}}^{\otimes}_{ne}) \longrightarrow \widetilde{\mathcal{O}}^{\otimes}_{ne}$$

is cocartesian. For this, by [Lur09, 6.1.1.1], it suffices to show that $\widetilde{\mathcal{O}}^{\otimes}_{ne}$ admits pushouts. Since the inert edges in $\widetilde{\mathcal{O}}^{\otimes}$ are defined to be the cocartesian lifts of inert edges in $\underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*}$, we may reduce to the case $\widetilde{\mathcal{O}}^{\otimes} = \underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*}$. It then suffices to show that $\mathrm{Ar}(\mathbf{F}_{\mathcal{T}})^{\dagger}$ (as in Definition 2.7.1) admits pullbacks. So suppose we have a commutative cube

$$\begin{array}{ccccccc}
 & & W \times_U X & \longrightarrow & & & X \\
 & \swarrow & & & & \swarrow & \\
W & & \longrightarrow & & U & & \downarrow \\
 & & \downarrow & & & & \\
\downarrow & & Z \times_V Y & \longrightarrow & \downarrow & & Y \\
 & \swarrow & & & & \swarrow & \\
Z & & \longrightarrow & & V & &
\end{array}$$

We want to show that if $W \longrightarrow Z \times_V U$ is a summand inclusion, then $W \times_U X \longrightarrow Z \times_Y X$ is a summand inclusion. To see this, consider the diagram

$$\begin{array}{ccccc}
W \times_U X & \longrightarrow & Z \times_Y X & \longrightarrow & X \\
\downarrow & & \downarrow & & \downarrow \\
W & \longrightarrow & Z \times_V U & \longrightarrow & U
\end{array}$$

The right square and outer rectangle are both pullback squares, so the left square is as well. Since summand inclusions are stable under pullback, the desired conclusion follows.

(6) Let $s : n^{\lhd} \longrightarrow n^{\lhd} \times_{\widetilde{\mathcal{O}}^{\otimes}} \mathrm{Ar}^{ne}(\widetilde{\mathcal{O}}^{\otimes}) \times_{\widetilde{\mathcal{O}}^{\otimes}} \widetilde{\mathcal{C}}^{\otimes}$ be a cocartesian section of π defined as above. Suppose that $s(\{v\}) = (x \xrightarrow{e} y \in \widetilde{\mathcal{O}}^{\otimes}_{ne},\ c \in \widetilde{\mathcal{C}}^{\otimes}_{y})$ and e is a cocartesian lift of the inert morphism in $\underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*}$ defined by the square

$$\begin{array}{ccc}
U' & \longrightarrow & U \\
\downarrow{\scriptstyle \phi'} & & \downarrow{\scriptstyle \phi} \\
V' & \longrightarrow & V
\end{array}$$

in $\mathbf{F}_{\mathcal{T}}$. If $\Sigma = \{\sigma_1, ..., \sigma_n\}$ is given by squares σ_i

$$\begin{array}{ccc} U_i & \longrightarrow & U \\ \downarrow & & \downarrow \phi \\ V_i & \longrightarrow & V \end{array}$$

then let $\Sigma' = \{\sigma'_1, ..., \sigma'_n\}$ be given by the collection of squares σ'_i

$$\begin{array}{ccc} U_i \times_U U' & \longrightarrow & U' \\ \downarrow & & \downarrow \phi' \\ V_i \times_V V' & \longrightarrow & V'. \end{array}$$

Because summand inclusions are stable under pullback, the morphisms $U_i \times_U U' \longrightarrow U'$ are summand inclusions, and clearly induce an equivalence $\coprod_{1 \leq i \leq n} U_i \times_U U' \simeq U'$. Therefore, the data of (c, ϕ', Σ') defines a morphism $f_{c,\phi',\Sigma'} : n^{\lhd} \longrightarrow \widetilde{\mathcal{C}}^{\otimes}$ which is part of the categorical pattern defining the $\mathcal{T}$-operadic model structure on $\mathbf{sSet}^+_{/(\widetilde{\mathcal{C}}^{\otimes},\mathrm{Ne})}$. Moreover, by the analysis done in (5) we may identify the composite map

$$n^{\lhd} \longrightarrow n^{\lhd} \times_{\widetilde{\mathcal{O}}^{\otimes}} \mathrm{Ar}^{ne}(\widetilde{\mathcal{O}}^{\otimes}) \times_{\widetilde{\mathcal{O}}^{\otimes}} \widetilde{\mathcal{C}}^{\otimes} \longrightarrow \widetilde{\mathcal{C}}^{\otimes}$$

with $f_{c,\phi',\Sigma'}$.

(7) We check the following: suppose we have a commutative diagram

$$\begin{array}{ccccc} x_0 & \longrightarrow & x_1 & \longrightarrow & x_2 \\ \downarrow & & \downarrow & & \downarrow \\ y_0 & \longrightarrow & y_1 & \longrightarrow & y_2 \end{array}$$

in $\mathrm{Ar}^{ne}(\widetilde{\mathcal{O}}^{\otimes})$ and $c_0 \longrightarrow c_1 \longrightarrow c_2$ in $\widetilde{\mathcal{C}}^{\otimes}$ that covers $y_0 \longrightarrow y_1 \longrightarrow y_2$, such that $c_1 \longrightarrow c_2$ is an equivalence (so $y_1 \longrightarrow y_2$ is an equivalence), $x_1 \longrightarrow x_2$ is inert, $x_0 \longrightarrow x_1$ is an equivalence. Then $c_0 \longrightarrow c_1$ is inert if and only if $c_0 \longrightarrow c_2$ is inert. But this is clear from the definitions.

(8) It suffices to check the following: suppose we have a commutative diagram

$$\begin{array}{ccccc} x_0 & \longrightarrow & x_1 & \longrightarrow & x_2 \\ \downarrow & & \downarrow & & \downarrow \\ y_0 & \longrightarrow & y_1 & \longrightarrow & y_2 \end{array}$$

in $\mathrm{Ar}^{ne}(\widetilde{\mathcal{O}}^{\otimes})$ and $c_0 \longrightarrow c_1 \longrightarrow c_2$ in $\widetilde{\mathcal{C}}^{\otimes}$ that covers $y_0 \longrightarrow y_1 \longrightarrow y_2$, such that $x_0 \longrightarrow x_1$, $y_0 \longrightarrow y_1$, and $c_0 \longrightarrow c_1$ are inert. Then $\{x_1 \longrightarrow x_2,\ y_1 \longrightarrow y_2,\ c_1 \longrightarrow c_2\}$ are inert if and only if $\{x_0 \longrightarrow x_2,\ y_0 \longrightarrow y_2,\ c_0 \longrightarrow c_2\}$ are inert. But this follows from the right cancellativity of inert morphisms (Remark 2.8.2).

□

Having passed to the big $\mathcal{T}$-∞-operads to construct the $\mathcal{T}$-operadic coinduction and verify its properties, we now pass back to the usual formulation of $\mathcal{T}$-∞-operads.

3.1.5. **Corollary.** *Let $\mathcal{O}^{\otimes}$ be a $\mathcal{T}$-∞-operad and let $(\mathcal{C}^{\otimes}, p)$ be an $\mathcal{O}$-promonoidal $\mathcal{T}$-∞-category. Consider the span diagram of marked simplicial sets*

$$(\mathcal{O}^{\otimes}, \mathrm{Ne}) \xleftarrow{\mathrm{ev}_0} (\mathrm{Ar}^{ne}(\mathcal{O}^{\otimes}) \times_{\mathcal{O}^{\otimes}} \mathcal{C}^{\otimes}, \mathrm{Ne}) \xrightarrow{\mathrm{pr}_{\mathcal{C}^{\otimes}}} (\mathcal{C}^{\otimes}, \mathrm{Ne}).$$

Then the functor

$$(\mathrm{ev}_0)_* \circ (\mathrm{pr}_{\mathcal{C}^{\otimes}})^* : \mathbf{sSet}^+_{/(\mathcal{C}^{\otimes},\mathrm{Ne})} \longrightarrow \mathbf{sSet}^+_{/(\mathcal{O}^{\otimes},\mathrm{Ne})}$$

is right Quillen with respect to the $\mathcal{T}$-operadic model structures.

Proof. Combine Theorem 3.1.4, Proposition 2.7.4, and Corollary 2.7.5. □

3.1.6. **Definition.** In the situation of Corollary 3.1.5, given a fibration of $\mathcal{T}$-∞-operads $\mathcal{E}^{\otimes} \longrightarrow \mathcal{C}^{\otimes}$, define the *p-operadic coinduction* or *p-norm* of $\mathcal{E}^{\otimes}$ to be the $\mathcal{T}$-∞-operad

$$(\mathrm{Norm}_p \mathcal{E})^{\otimes} := (\mathrm{ev}_0)_* (\mathrm{pr}_{\mathcal{C}^{\otimes}})^* (\mathcal{E}^{\otimes}, \mathrm{Ne}),$$

given as a marked simplicial set fibered over $(\mathcal{O}^{\otimes}, \mathrm{Ne})$.

Given a fibration of $\mathcal{T}$-∞-operads $\mathcal{E}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$, define the *Day convolution* $\mathcal{T}$-∞-operad to be

$$\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{E})^{\otimes} := (\mathrm{Norm}_p p^* \mathcal{E})^{\otimes}.$$

If $\mathcal{O}^{\otimes} = \underline{\mathbf{F}}_{\mathcal{T},*}$, we will also denote $\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{E})^{\otimes}$ as $\underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{C}, \mathcal{E})^{\otimes}$.

3.1.7. **Proposition.** *Let $p, q : \mathcal{D}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ be fibrations of $\mathcal{T}$-∞-operads. Then the functor*

$$\iota : (\mathcal{D}^{\otimes} \times_{\mathcal{O}^{\otimes}} \mathcal{C}^{\otimes}, \mathrm{Ne}) \longrightarrow (\mathcal{D}^{\otimes} \times_{\mathcal{O}^{\otimes}} \mathrm{Ar}^{ne}(\mathcal{O}^{\otimes}) \times_{\mathcal{O}^{\otimes}} \mathcal{C}^{\otimes}, \mathrm{Ne})$$

induced by the identity section is a homotopy equivalence in $\mathbf{sSet}^+_{/(\mathcal{C}^{\otimes},\mathrm{Ne})}$. Consequently, for $\mathcal{O}$-promonoidal $(\mathcal{C}^{\otimes}, p)$, ι^* induces an equivalence of $\mathcal{T}$-∞-categories

$$\underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{D}, \mathrm{Norm}_p \mathcal{E}) \xrightarrow{\simeq} \underline{\mathbf{Alg}}_{\mathcal{C},\mathcal{T}}(\mathcal{D} \times_{\mathcal{O}} \mathcal{C}, \mathcal{E})$$

and an equivalence of ∞-categories

$$\mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{D}, \mathrm{Norm}_p \mathcal{E}) \xrightarrow{\simeq} \mathbf{Alg}_{\mathcal{C},\mathcal{T}}(\mathcal{D} \times_{\mathcal{O}} \mathcal{C}, \mathcal{E}).$$

Proof. Let $P : \mathcal{D}^{\otimes} \times_{\mathcal{O}^{\otimes}} \mathrm{Ar}^{ne}(\mathcal{O}^{\otimes}) \longrightarrow \mathcal{D}^{\otimes}$ be a cocartesian pushforward chosen so that $P|_{\mathcal{D}^{\otimes}} = \mathrm{id}$, and let

$$P' = P \times \mathrm{id}_{\mathcal{C}^{\otimes}} : \mathcal{D}^{\otimes} \times_{\mathcal{O}^{\otimes}} \mathrm{Ar}^{ne}(\mathcal{O}^{\otimes}) \times_{\mathcal{O}^{\otimes}} \mathcal{C}^{\otimes} \longrightarrow \mathcal{D}^{\otimes} \times_{\mathcal{O}^{\otimes}} \mathcal{C}^{\otimes}.$$

Then P' respects the given markings, and as in the proof of [Sha21a, Lem. 3.2(2)] we may construct an explicit homotopy $h : \mathrm{id} \longrightarrow \iota \circ P'$ such that h sends objects to fiberwise marked edges. This shows that P is a marked homotopy inverse to ι and hence ι is a homotopy equivalence in $\mathbf{sSet}^+_{/(\mathcal{C}^{\otimes},\mathrm{Ne})}$. The consequences then follow from the definition of the left adjoint to Norm_p. □

3.1.8. **Corollary.** *The Quillen adjunction of Corollary 3.1.5 descends to an adjunction of ∞-categories*

$$p^* \colon (\mathbf{Op}_{\mathcal{T}})_{/\mathcal{O}^{\otimes}} \rightleftarrows (\mathbf{Op}_{\mathcal{T}})_{/\mathcal{C}^{\otimes}} : \mathrm{Norm}_p.$$

In particular, if $(\mathcal{C}^{\otimes}, p)$ is $\mathcal{O}$-promonoidal, then the right adjoint to p^* exists and is computed by Norm_p.

3.1.9. **Proposition.** *The underlying $\mathcal{T}$-∞-category of $\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{E})^{\otimes}$ is the $\mathcal{T}$-pairing construction $\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{E})$ of* [Sha21a, Constr. 9.1]. *In particular, if $\mathcal{O}^{\otimes} = \underline{\mathbf{F}}_{\mathcal{T},*}$, the underlying $\mathcal{T}$-∞-category of $\underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{C}, \mathcal{E})^{\otimes}$ is $\underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{C}, \mathcal{E})$.*

Proof. Consider the diagram

$$\begin{array}{ccccc}
\mathrm{Ar}^{cocart}(\mathcal{O}) \times_{\mathcal{O}} \mathcal{C} & \longrightarrow & \mathcal{O} & & \\
\downarrow \iota & & & \searrow & \\
\mathcal{O} \times_{\mathcal{O}^{\otimes}} \mathrm{Ar}^{ne}(\mathcal{O}^{\otimes}) \times_{\mathcal{O}^{\otimes}} \mathcal{C}^{\otimes} & \longrightarrow & \mathrm{Ar}^{ne}(\mathcal{O}^{\otimes}) \times_{\mathcal{O}^{\otimes}} \mathcal{C}^{\otimes} & \longrightarrow & \mathcal{O}^{\otimes} \\
\downarrow & & \downarrow & & \\
\mathcal{O} & \longrightarrow & \mathcal{O}^{\otimes} & &
\end{array}$$

where ι is defined using the inclusions $\mathcal{O} \subset \mathcal{O}^{\otimes}$ and $\mathcal{C} \subset \mathcal{C}^{\otimes}$. Unwinding the definitions, to prove the claim it suffices to show that the map

$$\mathrm{Ar}^{cocart}(\mathcal{O}) \times_{\mathcal{O}} \mathcal{C} \longrightarrow \mathcal{O} \times_{\mathcal{O}^{\otimes}} \mathrm{Ar}^{ne}(\mathcal{O}^{\otimes}) \times_{\mathcal{O}^{\otimes}} \mathcal{O} \times_{\mathcal{O}} \mathcal{C}$$

is a homotopy equivalence (in $\mathbf{sSet}^+_{/_\natural \mathcal{O}}$ via the target map). But this is clear, since the inert edges in $\mathcal{O}^{\otimes}$ with source and target in $\mathcal{O}$ are, up to equivalence, precisely the cocartesian edges in $\mathcal{O}$. □

3.2. **$\mathcal{O}$-monoidality of the $\mathcal{T}$-Day convolution.** We now establish $\mathcal{O}$-monoidality of the $\mathcal{T}$-Day convolution $\mathcal{T}$-∞-operad given appropriate conditions on the input $\mathcal{T}$-∞-operads. For this, we will use repeatedly the following criterion for when a fibration of $\mathcal{T}$-∞-operads is locally cocartesian or cocartesian.

3.2.1. **Lemma.** *Let $p : \mathcal{C}^\otimes \longrightarrow \mathcal{O}^\otimes$ be a fibration of $\mathcal{T}$-∞-operads. Suppose that for every fiberwise active edge $e : x \longrightarrow y$ in $\mathcal{O}^\otimes$ with $y \in \mathcal{O}$, and $c \in \mathcal{O}^\otimes$ with $p(c) = x$, there exists a locally cocartesian edge $f : c \longrightarrow c'$ over e. Then p is a locally cocartesian fibration.*

Furthermore, suppose that for every composition of fiberwise active edges $x \xrightarrow{e} y \xrightarrow{e'} z$ in $\mathcal{O}^\otimes$ with $z \in \mathcal{O}$, and $c \in \mathcal{O}^\otimes$ with $p(c) = x$, locally cocartesian lifts of e to $f : c \longrightarrow c'$ and e' to $f' : c' \longrightarrow c''$ compose to yield a locally cocartesian edge $f'' : c \longrightarrow c''$. Then p is a cocartesian fibration.

Proof. For the first assertion, using the inert-fiberwise active factorization system on $\mathcal{O}^\otimes$ and that p admits cocartesian lifts over inert edges, we reduce to checking that p admits locally cocartesian lifts over fiberwise active edges. Then given any fiberwise active edge $e : x \longrightarrow y$ in $\mathcal{O}^\otimes$, we may use that $\mathcal{O}^\otimes$ is a $\mathcal{T}$-∞-operad to obtain a decomposition of e as $(e_i : x_i \longrightarrow y_i)_{i\in I}$ for $y_i \in \mathcal{O}$ under the identifications $\mathcal{O}^\otimes_y \simeq \prod_{i\in I} \mathcal{O}^\otimes_{y_i}$, $\mathcal{O}^\otimes_x \simeq \prod_{i\in I} \mathcal{O}^\otimes_{x_i}$, and $\mathrm{Map}_{\mathcal{O}^\otimes_{act}}(x, y) \simeq \prod_{i\in I} \mathrm{Map}_{\mathcal{O}^\otimes_{act}}(x_i, y_i)$. Suppose $c \in \mathcal{C}^\otimes$ over x. Because p is a fibration of $\mathcal{T}$-∞-operads, we get $c_i \in \mathcal{C}^\otimes$ over x_i, and we may take the product of locally cocartesian lifts $c_i \longrightarrow c'_i$ over the e_i to obtain the desired locally cocartesian lift $c \longrightarrow c'$ of e.

For the second assertion, we need to check that locally cocartesian edges compose to yield again a locally cocartesian edge. Note that for any commutative diagram in $\mathcal{C}^\otimes$

$$\begin{array}{ccc} c & \xrightarrow{f} & d \\ \downarrow{\scriptstyle g} & & \downarrow{\scriptstyle g'} \\ c' & \xrightarrow{f'} & d' \end{array}$$

with f locally cocartesian over a fiberwise active edge and g, g' inert, then f' is necessarily locally cocartesian. Using this, we can reduce to checking that locally cocartesian edges over fiberwise active edges compose. Then as before, we can further reduce to supposing that the last object lies in $\mathcal{O}$. □

The next proposition allows us to understand $\mathcal{T}$-Day convolution as a *locally* cocartesian fibration over the base $\mathcal{T}$-∞-operad $\mathcal{O}^\otimes$.

3.2.2. **Proposition.** *Let $(\mathcal{C}^\otimes, p)$ be an $\mathcal{O}$-promonoidal $\mathcal{T}$-∞-category and let $(\mathcal{E}^\otimes, q)$ be an $\mathcal{O}$-monoidal $\mathcal{T}$-∞-category in which for every object $x \in \mathcal{O}_V$, the parametrized fiber $\mathcal{E}_{\underline{x}}$ is $\mathcal{T}^{/V}$-cocomplete.*

(1) The $\mathcal{T}$-Day convolution $\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{E})^\otimes \longrightarrow \mathcal{O}^\otimes$ is a locally cocartesian fibration, and for every $x \in \mathcal{O}_V$, its parametrized fiber $\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{E})_{\underline{x}}$ is $\mathcal{T}^{/V}$-cocomplete.

(2) Suppose $\overline{\alpha}$ is a fiberwise active edge in $\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{E})^\otimes_{\underline{V}}$ lifting $\alpha : x \longrightarrow y$ in $\mathcal{O}^\otimes_{\underline{V}}$ with $y \in \mathcal{O}_V$, which in turn lifts $f : U \longrightarrow V$ in $\mathbf{F}_\mathcal{T}$ (identified with the fiberwise active edge $[U_+ \to V] \longrightarrow [V_+ \to V]$ in $\underline{\mathbf{F}}_{\mathcal{T},*}$). The data of $\overline{\alpha}$ is given by a commutative diagram of $\mathcal{T}^{/V}$-∞-categories

$$\begin{array}{ccc} \{x\} \times_{\mathcal{O}^\otimes} \mathrm{Ar}^{ne}(\mathcal{O}^\otimes) \times_{\mathcal{O}^\otimes} \mathcal{C}^\otimes & \xrightarrow{F} & \mathcal{E}^\otimes_{\underline{V}} \\ \downarrow{\scriptstyle i} & \overset{H}{\nearrow} & \downarrow{\scriptstyle q_{\underline{V}}} \\ \Delta^1 \times_{\alpha,\mathcal{O}^\otimes} \mathrm{Ar}^{ne}(\mathcal{O}^\otimes) \times_{\mathcal{O}^\otimes} \mathcal{C}^\otimes & \longrightarrow & \mathcal{O}^\otimes_{\underline{V}} \end{array}$$

where we use the projections of the lefthand ∞-categories to $\{V\} \times_{\mathcal{T}^{\mathrm{op}}} \mathrm{Ar}(\mathcal{T}^{\mathrm{op}}) \cong (\mathcal{T}^{/V})^{\mathrm{op}}$ in order to pullback to the base $(\mathcal{T}^{/V})^{\mathrm{op}}$.

Then $\overline{\alpha}$ is a locally cocartesian edge if and only if H is a weak $q_{\underline{V}}$-$\mathcal{T}^{/V}$-left Kan extension of F in the sense of [Sha21b, Def. 6.1].

(3) Note that we have inclusions of full $\mathcal{T}$-subcategories

$$\mathcal{C}^\otimes_{\underline{x}} := \{x\} \times_{\mathcal{O}^\otimes} \mathrm{Ar}^{cocart}(\mathcal{O}^\otimes) \times_{\mathcal{O}^\otimes} \mathcal{C}^\otimes \subset \{x\} \times_{\mathcal{O}^\otimes} \mathrm{Ar}^{ne}(\mathcal{O}^\otimes) \times_{\mathcal{O}^\otimes} \mathcal{C}^\otimes$$
$$\mathcal{C}^\otimes_{\underline{\alpha}} := \Delta^1 \times_{\alpha,\mathcal{O}^\otimes} \mathrm{Ar}^{cocart}(\mathcal{O}^\otimes) \times_{\mathcal{O}^\otimes} \mathcal{C}^\otimes \subset \Delta^1 \times_{\alpha,\mathcal{O}^\otimes} \mathrm{Ar}^{ne}(\mathcal{O}^\otimes) \times_{\mathcal{O}^\otimes} \mathcal{C}^\otimes.$$

Choose a cocartesian pushforward $P_\alpha : \mathcal{E}^{\otimes}_{\underline{\alpha}} \longrightarrow \mathcal{E}_{\underline{y}}$ and consider the commutative diagram

$$\begin{array}{ccccc} \mathcal{C}^{\otimes}_{\underline{x}} & \xrightarrow{F} & \mathcal{E}^{\otimes}_{\underline{\alpha}} & \xrightarrow{P_\alpha} & \mathcal{E}_{\underline{y}} \\ {\scriptstyle i}\downarrow & \nearrow{\scriptstyle H} & & & \downarrow \\ \mathcal{C}^{\otimes}_{\underline{\alpha}} & & \longrightarrow & & (\mathcal{T}^{/V})^{\mathrm{op}} \end{array}$$

(where we abusively continue to write H and F for the canonical lifts of those functors to have codomains $\mathcal{E}^{\otimes}_{\underline{\alpha}}$ and $\mathcal{E}^{\otimes}_{\underline{x}} \subset \mathcal{E}^{\otimes}_{\underline{\alpha}}$ respectively). Then $\overline{\alpha}$ is a locally cocartesian edge if and only if $P_\alpha \circ H$ is a $\mathcal{T}^{/V}$-left Kan extension of $P_\alpha \circ F$.

Furthermore, if we let $G = (P_\alpha \circ H)|_{\mathcal{C}_{\underline{y}}} : \mathcal{C}_{\underline{y}} \longrightarrow \mathcal{E}_{\underline{y}}$, then we have the data of a diagram

$$\begin{array}{ccccc} \mathcal{C}^{\otimes}_{\underline{x}} & \xrightarrow{F} & \mathcal{E}^{\otimes}_{\underline{x}} & \xrightarrow{\alpha_\otimes} & \mathcal{E}_{\underline{y}} \\ {\scriptstyle \alpha_\otimes}\downarrow & \Downarrow\eta & & \nearrow & \\ \mathcal{C}_{\underline{y}} & & \xrightarrow{G} & & \end{array}$$

in which the natural transformation η exhibits G as a $\mathcal{T}^{/V}$-left Kan extension of $\alpha_\otimes \circ F$ along $\alpha_\otimes$.

Proof. (2): By definition, $\overline{\alpha}$ is a locally cocartesian edge if and only if H is initial in the space of all such fillers. But if H is a weak $q_{\underline{V}}$-$\mathcal{T}^{/V}$-left Kan extension of F, then it is in particular initial. Conversely, provided that we know a weak $q_{\underline{V}}$-$\mathcal{T}^{/V}$-left Kan extension of F exists, then it necessarily coincides with the filler defined by $\overline{\alpha}$.

(1): We now show existence of these weak $q_{\underline{V}}$-$\mathcal{T}^{/V}$-left Kan extensions. Let

$$K := \{x\} \times_{\mathcal{O}^{\otimes}} \mathrm{Ar}^{ne}(\mathcal{O}^{\otimes}) \times_{\mathcal{O}^{\otimes}} \mathcal{C}^{\otimes}$$
$$L := \Delta^1 \times_{\alpha, \mathcal{O}^{\otimes}} \mathrm{Ar}^{ne}(\mathcal{O}^{\otimes}) \times_{\mathcal{O}^{\otimes}} \mathcal{C}^{\otimes}.$$

Note that any object in L that is not in K is either of the form $(y \to z = p(c) \in \mathrm{Ar}^{cocart}(\mathcal{O}),\ c \in \mathcal{C})$ or $(y \to z = p(c) \in \mathrm{Ar}^{ne}(\mathcal{O}^{\otimes}),\ c \in \mathcal{C}^{\otimes})$ with z over $[\emptyset_+ \to W] \in \underline{\mathbf{F}}_{\mathcal{T},*}$. Let $L_0 \subset L$ denote the full $\mathcal{T}$-subcategory excluding the second type of objects. Because the fiber of $\mathcal{E}^{\otimes}$ over any object $[\emptyset_+ \to W] \in \underline{\mathbf{F}}_{\mathcal{T},*}$ is contractible, we may replace L with L_0 and instead consider fillers $H_0 : L_0 \longrightarrow \mathcal{E}^{\otimes}$. Moreover, note that there are no inert edges in L_0 not either cocartesian over $\mathcal{T}^{\mathrm{op}}$ or in K, so any extension H_0 necessarily defines an edge of $\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{E})^{\otimes}$.

Because both the additional objects in L_0 and morphisms between those objects lie over $\underline{y} \longrightarrow \mathcal{O} \subset \mathcal{O}^{\otimes}$, by [Sha21b, Thm. 6.2] in conjunction with [Sha21b, Prop. 5.8] it suffices to have $\mathcal{E}_{\underline{y}}$ be $\mathcal{T}^{/V}$-cocomplete for a weak $q_{\underline{V}}$-$\mathcal{T}^{/V}$-left Kan extension of F to exist. This is ensured by our hypothesis.

By Lemma 3.2.1, we see that the case we just considered suffices to show that $\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{E})^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ is a locally cocartesian fibration. In addition, by Proposition 3.1.9 and [Sha21a, Prop. 9.7], for every $x \in \mathcal{O}_V$ we have an equivalence

$$\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{E})_{\underline{x}} \simeq \underline{\mathrm{Fun}}_{\underline{V}}(\mathcal{C}_{\underline{x}}, \mathcal{E}_{\underline{x}}),$$

and the latter $\mathcal{T}^{/V}$-∞-category is $\mathcal{T}^{/V}$-cocomplete by the pointwise computation of $\mathcal{T}^{/V}$-colimits in $\mathcal{T}^{/V}$-functor categories.

(3): Observe that for $l = (y \to z, c) \in \mathcal{C}^{\otimes}_{\underline{\alpha}} \subset L$, $K \times_L L^{/\underline{l}} \simeq \mathcal{C}^{\otimes}_{\underline{x}} \times_{\mathcal{C}^{\otimes}_{\underline{\alpha}}} (\mathcal{C}^{\otimes}_{\underline{\alpha}})^{/\underline{l}}$. By the pointwise formula for $\mathcal{T}^{/V}$-left Kan extensions, the first part of the claim follows. The second part then follows by [Sha21b, Rem. 2.14]. □

As with ordinary Day convolution, we need an additional distributivity hypothesis on the target for $\mathcal{T}$-Day convolution to be $\mathcal{O}$-monoidal. We first recall the definition of a distributive functor (as originally formulated by the first author).

3.2.3. **Definition** ([Sha21b, Def. 8.18]). Let $f : U \longrightarrow V$ be a map of finite $\mathcal{T}$-sets, let $\mathcal{C}$ be a $\mathcal{T}^{/U}$-∞-category, and let $\mathcal{D}$ be a $\mathcal{T}^{/V}$-∞-category. Let $F : \prod_f \mathcal{C} = f_* \mathcal{C} \longrightarrow \mathcal{D}$ be a $\mathcal{T}^{/V}$-functor. Then we say that

F is *distributive* if for every pullback square

$$\begin{array}{ccc} U' & \xrightarrow{f'} & V' \\ \downarrow{g'} & & \downarrow{g} \\ U & \xrightarrow{f} & V \end{array}$$

of finite $\mathcal{T}$-sets and $\mathcal{T}^{/U'}$-colimit diagram $\overline{p} : \mathcal{K}^{\underline{\triangleright}} \longrightarrow g'^*\mathcal{C}$, the $\mathcal{T}^{/V'}$-functor

$$(f'_*\mathcal{K})^{\underline{\triangleright}} \xrightarrow{\text{can}} f'_*(\mathcal{K}^{\underline{\triangleright}}) \xrightarrow{f'_*\overline{p}} f'_*g'^*\mathcal{C} \simeq g^*f_*\mathcal{C} \xrightarrow{g^*F} g^*\mathcal{D}$$

is a $\mathcal{T}^{/V'}$-colimit diagram.

3.2.4. **Definition.** Let $\mathcal{C}^{\otimes}$ be a $\mathcal{O}$-monoidal $\mathcal{T}$-∞-category and suppose that for all $y \in \mathcal{O}_V$, $\mathcal{C}_{\underline{y}}$ is $\mathcal{T}^{/V}$-cocomplete. We say that $\mathcal{C}^{\otimes}$ is *distributive* if for every fiberwise active edge $\alpha : x \longrightarrow y$ lifting $[U_+ \to V] \longrightarrow [V_+ \to V]$ (corresponding to $f : U \longrightarrow V$ in $\mathbf{F}_{\mathcal{T}}$), the associated pushforward $\mathcal{T}^{/V}$-functor

$$\alpha_{\otimes} : \mathcal{C}^{\otimes}_{\underline{x}} \longrightarrow \mathcal{C}_{\underline{y}}$$

is distributive. Here, for this condition to be sensible, we use that for an orbit decomposition $U \simeq U_1 \coprod ... \coprod U_n$ and n cocartesian morphisms $x \longrightarrow x_i$ lifting the characteristic maps $\chi_{[U_i \subset U]} : [U_+ \to V] \longrightarrow [(U_i)_+ \to U_i]$, the parametrized fiber $\mathcal{C}^{\otimes}_{\underline{x}}$ is identified with $\prod_f \left(\mathcal{C}_{\underline{x_1}} \coprod ... \coprod \mathcal{C}_{\underline{x_n}}\right)$ by the $\mathcal{T}$-Segal condition (cf. Example 2.3.5).

Also note that in particular, for each morphism $\alpha : x \longrightarrow y$ in $\mathcal{O}_V$, the condition that the pushforward $\mathcal{T}^{/V}$-functor $\alpha_{\otimes} : \mathcal{C}_{\underline{x}} \longrightarrow \mathcal{C}_{\underline{y}}$ is distributive is equivalent to $\alpha_{\otimes}$ strongly preserving all small $\mathcal{T}^{/V}$-colimits.

The following proposition furnishes some examples of distributive $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-categories.

3.2.5. **Proposition.** *Let $\mathcal{C}$ be a cocomplete ∞-category with finite products such that the products commute with colimits separately in each variable. Let $f : U \longrightarrow U'$ be a morphism of finite $\mathcal{T}$-sets. Then the product $\mathcal{T}^{/U'}$-functor*

$$\mu : f_*f^*\underline{\mathcal{C}}_{\mathcal{T}/U'} \longrightarrow \underline{\mathcal{C}}_{\mathcal{T}/U'}$$

is distributive. Consequently, the $\mathcal{T}$-cartesian $\mathcal{T}$-symmetric monoidal structure on $\underline{\mathcal{C}}_{\mathcal{T}}$ is $\mathcal{T}$-distributive.

Proof. By the universal property of the category of $\mathcal{T}^{/U'}$-objects ([Sha21a, Prop. 3.10]), μ can be identified with a functor

$$\mu^{\dagger} : f_*f^*\underline{\mathcal{C}}_{\mathcal{T}/U'} \longrightarrow \mathcal{C}$$

such that its restriction to the fiber over $[W \to U'] \in \mathcal{T}^{/U'}$ is the functor

$$\prod_{V \in \mathrm{Orbit}(U \times_{U'} W)} \mathrm{Fun}(\underline{V}, \mathcal{C}) \xrightarrow{\prod \mathrm{ev}_V} \prod_{V \in \mathrm{Orbit}(U \times_{U'} W)} \mathcal{C} \xrightarrow{\times} \mathcal{C}\,.$$

For the proof of distributivity we can assume without loss of generality that U' is an orbit. Suppose $p : \mathcal{K}^{\underline{\triangleright}} \longrightarrow \underline{\mathcal{C}}_{\mathcal{T}/U}$ is a $\mathcal{T}^{/U}$-colimit diagram and let $p^{\dagger} : \mathcal{K}^{\underline{\triangleright}} \longrightarrow \mathcal{C}$ be the functor under the equivalence of [Sha21a, Prop. 3.10]. By [Sha21a, Prop. 5.5], any such p is $\mathcal{T}^{/U}$-colimit diagram if and only if for every $[V \to U] \in \mathcal{T}^{/U}$ the functor $p^{\dagger}_V : \mathcal{K}^{\triangleright}_{[V \to U]} \longrightarrow \mathcal{C}$ given by restriction to the fiber is a colimit diagram. By [Sha21a, Prop. 5.5] again, it suffices to prove that the diagram

$$(f_*\mathcal{K})^{\underline{\triangleright}} \longrightarrow f_*\underline{\mathcal{C}}_{\mathcal{T}/U} \xrightarrow{\mu^{\dagger}} \mathcal{C}$$

is a colimit diagram when restricted to each fiber. But the restriction to the fiber above $[W \to U'] \in \mathcal{T}^{/U'}$ is

$$\left(\prod_{V \in \mathrm{Orbit}(U \times_{U'} W)} \mathcal{K}_V\right)^{\triangleright} \longrightarrow \prod_{V \in \mathrm{Orbit}(U \times_{U'} W)} \mathcal{K}_V^{\triangleright} \xrightarrow{\prod p_V} \prod_{V \in \mathrm{Orbit}(U \times_{U'} W)} \mathcal{C} \xrightarrow{\times} \mathcal{C},$$

which is a colimit diagram since the cartesian product in $\mathcal{C}$ commutes with colimits separately in each variable. □

We now return to $\mathcal{T}$-Day convolution and prove the main result of this subsection.

3.2.6. **Theorem.** *In the situation of Proposition 3.2.2, suppose moreover that* $q : \mathcal{E}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ *is distributive. Then* $\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C},\mathcal{E})^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ *is a cocartesian fibration and* $\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C},\mathcal{E})^{\otimes}$ *is distributive.*

Proof. Let

$$\begin{array}{ccccc} & & y & & \\ & \overset{\alpha}{\nearrow} & & \overset{\beta}{\searrow} & \\ x & & \xrightarrow{\gamma} & & z \end{array}$$

be a 2-simplex σ of fiberwise active edges in $\mathcal{O}^{\otimes}_{W}$ with $z \in \mathcal{O}_W$, which covers

$$\begin{array}{ccccc} & & V & & \\ & \overset{f}{\nearrow} & & \overset{g}{\searrow} & \\ U & & \xrightarrow{h} & & W \end{array}$$

in $\mathbf{F}_{\mathcal{T}}$ (viewed as a 2-simplex in $(\underline{\mathbf{F}}_{\mathcal{T},*})^{act}_{W}$). We need to verify that given a lift of σ to a 2-simplex $\overline{\sigma}$

$$\begin{array}{ccccc} & & \overline{y} & & \\ & \overset{\overline{\alpha}}{\nearrow} & & \overset{\overline{\beta}}{\searrow} & \\ \overline{x} & & \xrightarrow{\overline{\gamma}} & & \overline{z} \end{array}$$

in $\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C},\mathcal{E})^{\otimes}$, if $\overline{\alpha}$ and $\overline{\beta}$ are locally cocartesian edges then $\overline{\gamma}$ is a locally cocartesian edge.

Suppose that $V \simeq \coprod_{1 \leq i \leq n} V_i$ is an orbit decomposition of V with respect to which α decomposes as $\{\alpha_i : x_i \longrightarrow y_i\}_{1 \leq i \leq n}$. Then the locally cocartesian edge $\overline{\alpha}$ corresponds to n commutative diagrams of $\mathcal{T}^{/V_i}$-∞-categories

$$\begin{array}{ccc} \mathcal{C}^{\otimes}_{\underline{x_i}} & \xrightarrow{F_{x_i}} & \mathcal{E}_{\underline{y_i}} \\ \downarrow & \overset{F_{\alpha_i}}{\nearrow} & \\ \mathcal{C}^{\otimes}_{\underline{\alpha_i}} & & \end{array}$$

in which F_{α_i} is a $\mathcal{T}^{/V_i}$-left Kan extension of F_{x_i}. From this, we obtain the commutative diagram of $\mathcal{T}^{/W}$-∞-categories

$$\begin{array}{ccccc} \prod_g(\coprod_{1 \leq i \leq n} \mathcal{C}^{\otimes}_{\underline{x_i}}) \simeq \mathcal{C}^{\otimes}_{\underline{x}} & \xrightarrow{F_x} & \prod_g(\coprod_{1 \leq i \leq n} \mathcal{E}_{\underline{y_i}}) \simeq \mathcal{E}^{\otimes}_{\underline{y}} & \xrightarrow{\beta_{\otimes}} & \mathcal{E}_{\underline{z}} \\ \downarrow & \overset{F_{\alpha}}{\nearrow} & & \overset{\beta_{\otimes} \circ F_{\alpha}}{\nearrow} & \\ \prod_g(\coprod_{1 \leq i \leq n} \mathcal{C}^{\otimes}_{\underline{\alpha_i}}) \simeq \mathcal{C}^{\otimes}_{\underline{\alpha}} & & & & \end{array}$$

in which $\beta_{\otimes} \circ F_{\alpha}$ is a $\mathcal{T}^{/W}$-left Kan extension of $\beta_{\otimes} \circ F_x$, invoking the hypothesis that $\mathcal{E}^{\otimes}$ is distributive.

On the other hand, the locally cocartesian edge $\overline{\beta}$ corresponds to a commutative diagram of $\mathcal{T}^{/W}$-∞-categories

$$\begin{array}{ccc} \mathcal{C}^{\otimes}_{\underline{y}} & \xrightarrow{F_{y}} & \mathcal{E}_{\underline{z}} \\ \downarrow & \overset{F_{\beta}}{\nearrow} & \\ \mathcal{C}^{\otimes}_{\underline{\beta}} & & \end{array}$$

in which F_y is the restriction of $\beta_\otimes \circ F_\alpha$ along the inclusion $\mathcal{C}^\otimes_{\underline{y}} \subset \mathcal{C}^\otimes_{\underline{\alpha}}$ and F_β is a $\mathcal{T}^{/W}$-left Kan extension of F_y. Combining these two diagrams, we obtain a commutative diagram of $\mathcal{T}^{/W}$-∞-categories

$$\begin{array}{ccccc}
 & & \mathcal{C}^\otimes_{\underline{x}} & \xrightarrow{F_x} & \mathcal{E}^\otimes_{\underline{y}} \\
 & & \downarrow & & \downarrow{\scriptstyle \beta_\otimes} \\
\mathcal{C}^\otimes_{\underline{y}} & \longrightarrow & \mathcal{C}^\otimes_{\underline{\alpha}} & \xrightarrow{\beta_\otimes \circ F_\alpha} & \mathcal{E}_{\underline{z}} \\
\downarrow & \nearrow{\scriptstyle F_\beta} & \downarrow & \nearrow{\scriptstyle F_\sigma}\,(\text{dotted}) & \\
\mathcal{C}^\otimes_{\underline{\beta}} & \longrightarrow & \mathcal{C}^\otimes_{\underline{\sigma}} & &
\end{array}$$

where $\mathcal{C}^\otimes_{\underline{\sigma}} := \Delta^2 \times_{\sigma, \mathcal{O}^\otimes} \mathrm{Ar}^{cocart}(\mathcal{O}^\otimes) \times_{\mathcal{O}^\otimes} \mathcal{C}^\otimes$. Because $\mathcal{C}^\otimes$ is $\mathcal{O}$-promonoidal and σ is a 2-simplex of fiberwise active edges, the lefthand square is a pushout square of $\mathcal{T}^{/W}$-∞-categories, and the dotted $\mathcal{T}^{/W}$-functor F_σ is obtained from gluing together $\beta_\otimes \circ F_\alpha$ and F_β. Indeed, F_σ corresponds to the 2-simplex $\overline{\sigma}$ in $\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{E})^\otimes$. By Lemma 3.2.7, F_σ is a $\mathcal{T}^{/W}$-left Kan extension of $\beta_\otimes \circ F_\alpha$. By transitivity of $\mathcal{T}^{/W}$-left Kan extensions, F_σ is a $\mathcal{T}^{/W}$-left Kan extension of $\beta_\otimes \circ F_x$, and the restriction F_γ of F_σ to $\mathcal{C}^\otimes_{\underline{\gamma}} \subset \mathcal{C}^\otimes_{\underline{\sigma}}$ is also a $\mathcal{T}^{/W}$-left Kan extension of $\beta_\otimes \circ F_x$. But this exactly means that $\overline{\gamma}$ is a locally cocartesian edge. Finally, by Lemma 3.2.1 this suffices to show that $\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{E})^\otimes \longrightarrow \mathcal{O}^\otimes$ is a cocartesian fibration.

To show that $\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{E})^\otimes$ is distributive, we check the definition. So suppose that $\alpha : x \longrightarrow y$ is a fiberwise active edge in $\mathcal{O}^\otimes_V$ with $y \in \mathcal{O}_V$, which lifts $f : U \longrightarrow V$ in $\mathbf{F}_\mathcal{T}$. Let $U \simeq U_1 \coprod ... \coprod U_n$ be an orbit decomposition and suppose we have $\mathcal{T}^{/U_i}$-colimits

$$\begin{array}{ccc}
\mathcal{K}_i & \xrightarrow{p_i} & \underline{\mathrm{Fun}}_{\mathcal{T}^{/U_i}}(\mathcal{C}_{\underline{x_i}}, \mathcal{E}_{\underline{x_i}}) \\
\downarrow & \nearrow{\scriptstyle q_i} & \\
(\mathcal{T}^{/U_i})^{\mathrm{op}} & &
\end{array}$$

(Here and throughout we suppress the data of the natural transformations.) By [Sha21a, Prop. 9.17] and its proof, these are adjoint to $\mathcal{T}^{/U_i}$-left Kan extensions

$$\begin{array}{ccc}
\mathcal{K}_i \times_{(\mathcal{T}^{/U_i})^{\mathrm{op}}} \mathcal{C}_{\underline{x_i}} & \xrightarrow{p'_i} & \mathcal{E}_{\underline{x_i}} \\
\downarrow & \nearrow{\scriptstyle q'_i} & \\
\mathcal{C}_{\underline{x_i}} & &
\end{array}$$

Let $\mathcal{K} = \coprod_{1 \le i \le n} \mathcal{K}_i$, $p = \coprod_{1 \le i \le n} p_i$, and $q = \coprod_{1 \le i \le n} q_i$, and the same for $\mathcal{K}', p', q'$. We need to show that

$$\begin{array}{ccccc}
\prod_f \mathcal{K} & \xrightarrow{\prod_f p} & \widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{E})^\otimes_{\underline{x}} & \xrightarrow{\alpha_\otimes} & \underline{\mathrm{Fun}}_{\mathcal{T}^{/V}}(\mathcal{C}_{\underline{y}}, \mathcal{E}_{\underline{y}}) \\
\downarrow & & & \nearrow{\scriptstyle \alpha_\otimes \circ \prod_f q} & \\
(\mathcal{T}^{/V})^{\mathrm{op}} & & & &
\end{array}$$

is a $\mathcal{T}^{/V}$-colimit. Equivalently, we need to show that in the diagram

$$\begin{array}{ccccc}
\prod_f \mathcal{K} \times_{(\mathcal{T}^{/V})^{\mathrm{op}}} \mathcal{C}^{\otimes}_{\underline{x}} & \xrightarrow{(\prod_f p)'} & \mathcal{E}^{\otimes}_{\underline{x}} & \xrightarrow{\alpha_\otimes} & \mathcal{E}_{\underline{y}} \\
\downarrow & & & \nearrow_{(\alpha_\otimes \circ \prod_f p)'} & \\
\prod_f \mathcal{K} \times_{(\mathcal{T}^{/V})^{\mathrm{op}}} \mathcal{C}^{\otimes}_{\underline{\alpha}} & & & & \\
\downarrow & & \nearrow_{(\alpha_\otimes \circ \prod_f q)'} & & \\
\mathcal{C}^{\otimes}_{\underline{\alpha}} & & & &
\end{array}$$

the $\mathcal{T}^{/V}$-functor $(\alpha_\otimes \circ \prod_f q)'$ is a $\mathcal{T}^{/V}$-left Kan extension of $(\alpha_\otimes \circ \prod_f p)'$. Here we change the domain from $\mathcal{C}^{\otimes}_{\underline{y}}$ to $\mathcal{C}^{\otimes}_{\underline{\alpha}}$ because we are not supposing that $\mathcal{C}^{\otimes}$ is $\mathcal{O}$-monoidal. Note that $(\alpha_\otimes \circ \prod_f p)'$ is by definition a $\mathcal{T}^{/V}$-left Kan extension of $\alpha_\otimes \circ (\prod_f p)'$, so it suffices to show that $(\alpha_\otimes \circ \prod_f q)'$ is a $\mathcal{T}^{/V}$-left Kan extension of $\alpha_\otimes \circ (\prod_f p)'$.

Because $\mathcal{E}^{\otimes}$ is distributive, we have that

$$\begin{array}{ccccc}
\prod_f \mathcal{K} \times_{(\mathcal{T}^{/V})^{\mathrm{op}}} \mathcal{C}^{\otimes}_{\underline{x}} & \xrightarrow{\prod_f (p')} & \mathcal{E}^{\otimes}_{\underline{x}} & \xrightarrow{\alpha_\otimes} & \mathcal{E}_{\underline{y}} \\
\downarrow & & & \nearrow_{\alpha_\otimes \circ \prod_f (q')} & \\
\mathcal{C}^{\otimes}_{\underline{x}} & & & &
\end{array}$$

is a $\mathcal{T}^{/V}$-left Kan extension. By definition, $(\alpha_\otimes \circ \prod_f q)'$ is a $\mathcal{T}^{/V}$-left Kan extension of $\alpha_\otimes \circ \prod_f (q')$ along the inclusion $\mathcal{C}^{\otimes}_{\underline{x}} \subset \mathcal{C}^{\otimes}_{\underline{\alpha}}$. By transitivity of $\mathcal{T}^{/V}$-left Kan extensions, we are done. □

3.2.7. **Lemma.** *Suppose we have a diagram of $\mathcal{T}$-∞-categories*

$$\begin{array}{ccccc}
\mathcal{A} & \xrightarrow{i} & \mathcal{B} & \xrightarrow{F} & \mathcal{E} \\
\downarrow \phi & & \downarrow \phi & \nearrow_{H} & \\
\mathcal{C} & \xrightarrow{i} & \mathcal{D} & &
\end{array}$$

such that the lefthand square is a pushout square in which every $\mathcal{T}$-functor is an inclusion. Further suppose that the relevant $\mathcal{T}$-colimits exists for the $\mathcal{T}$-left Kan extensions of F along ϕ and of $F \circ i$ along ϕ to exist. Then H is a $\mathcal{T}$-left Kan extension of F if and only if $H \circ i$ is a $\mathcal{T}$-left Kan extension of $F \circ i$.

Proof. Consider the commutative diagram of $\mathcal{T}$-∞-categories

$$\begin{array}{ccccc}
\mathcal{P} & \longrightarrow & \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{D}, \mathcal{E}) & \longrightarrow & \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{C}, \mathcal{E}) \\
\sigma \uparrow\downarrow & & \downarrow & & \downarrow \\
\mathcal{T}^{\mathrm{op}} & \xrightarrow{\sigma_F} & \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{B}, \mathcal{E}) & \longrightarrow & \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{A}, \mathcal{E}) \\
 & & \underset{\sigma_{Fi}}{\curvearrowright} & &
\end{array}$$

in which every square is a pullback square. Then $\mathcal{P}$ is identified with

$$\mathcal{T}^{\mathrm{op}} \times_{\sigma_{Fi}, \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{A}, \mathcal{E})} \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{C}, \mathcal{E}) \simeq \mathcal{T}^{\mathrm{op}} \times_{\sigma_F, \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{B}, \mathcal{E})} \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{D}, \mathcal{E})$$

and the cocartesian section σ is equivalently determined by a $\mathcal{T}$-functor H extending F or a $\mathcal{T}$-functor G extending $F \circ i$. Moreover, because of our hypothesis on the existence of the relevant $\mathcal{T}$-colimits, σ is an $\mathcal{T}$-initial object in $\mathcal{P}$ if and only if H is a $\mathcal{T}$-left Kan extension of F along ϕ if and only if G is a $\mathcal{T}$-left Kan extension of $F \circ i$ along ϕ. □

3.2.8. **Example** (Smash product)**.** Define a functor

$$(\underline{\Delta^1})^{\otimes} : \mathrm{Span}(\mathbf{F}_{\mathcal{T}}) \longrightarrow \mathrm{hoSpan}(\mathbf{F}_{\mathcal{T}}) \longrightarrow \mathbf{Cat}_1$$

by sending an object $U = \coprod_I U_i$ (decomposed as a disjoint union of orbits) to $\prod_I \Delta^1$, and a morphism $f : \coprod_I U_i \longrightarrow \coprod_J V_j$, $\phi : I \longrightarrow J$ contravariantly to the restriction functor $\phi^* : \prod_J \Delta^1 \longrightarrow \prod_I \Delta^1$ and covariantly to the product over J of

$$\min : \prod_{I_j} \Delta^1 \longrightarrow \Delta^1,\ (x_i) \mapsto \min(x_i)$$

if I_j is nonempty, and $1 : \Delta^0 \longrightarrow \Delta^1$ otherwise. (One easily verifies the base-change condition, so this indeeds defines a functor.)

Let $(\Delta^1 \times \mathcal{T}^{\mathrm{op}})^{\otimes}$ denote the resulting $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-category under the equivalence of Theorem 2.3.9. Let $\mathcal{C}^{\otimes}$ be a distributive $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-category. Then by Theorem 3.2.6, we have that $\underline{\mathrm{Fun}}_{\mathcal{T}}(\Delta^1 \times \mathcal{T}^{\mathrm{op}}, \mathcal{C})^{\otimes}$ is a distributive $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-category. Moreover, the fiberwise tensor products admit a simple description because the underlying $\mathcal{T}$-category of the source is constant. Namely, for the fold map $\nabla : U \coprod U \longrightarrow U$, the tensor product

$$\otimes : \mathrm{Fun}(\Delta^1, \mathcal{C}_U) \times \mathrm{Fun}(\Delta^1, \mathcal{C}_U) \longrightarrow \mathrm{Fun}(\Delta^1, \mathcal{C}_U)$$

is given by taking the cartesian product into $\mathrm{Fun}(\Delta^1 \times \Delta^1, \mathcal{C}_U \times \mathcal{C}_U)$, postcomposition by $\otimes : \mathcal{C}_U \times \mathcal{C}_U \longrightarrow \mathcal{C}_U$, and then left Kan extension along $\min : \Delta^1 \times \Delta^1 \longrightarrow \Delta^1$ (which is computed by taking colimits fiberwise because min is a cocartesian fibration).

Now suppose in addition that $\mathcal{C}^{\otimes}$ is $\mathcal{T}$-*cartesian* $\mathcal{T}$-symmetric monoidal, so the tensor product on the fibers of $\underline{\mathrm{Fun}}_{\mathcal{T}}(\Delta^1 \times \mathcal{T}^{\mathrm{op}}, \mathcal{C})$ is the pushout product. Let $\mathcal{C}_*$ denote the full $\mathcal{T}$-subcategory of $\underline{\mathrm{Fun}}_{\mathcal{T}}(\Delta^1 \times \mathcal{T}^{\mathrm{op}}, \mathcal{C})$ given over an object $U \in \mathcal{T}$ by those functors $\Delta^1 \longrightarrow \mathcal{C}_U$ which take 0 to a final object $*$ of $\mathcal{C}_U$. The inclusion $\mathcal{C}_* \subset \underline{\mathrm{Fun}}_{\mathcal{T}}(\Delta^1 \times \mathcal{T}^{\mathrm{op}}, \mathcal{C})$ admits a left adjoint L, which over an object $U \in \mathcal{T}$ takes a functor $F : \Delta^1 \longrightarrow \mathcal{C}_U$ to

$$L(F) : \Delta^1 \longrightarrow \mathcal{C}_U,\ [0 \to 1] \rightsquigarrow [* \to F(1)/F(0)].$$

L is a $\mathcal{T}$-localization functor, so to descend the cartesian $\mathcal{T}$-symmetric monoidal structure on $\mathcal{C}$ to the *smash product* on $\mathcal{C}_*$, we can check the criterion of Theorem 2.9.2 (or rather, Remark 2.9.3):

(1) For the fold map $\nabla : U \coprod U \longrightarrow U$ and an object $[z_0 \longrightarrow z_1] \in \mathrm{Fun}(\Delta^1, \mathcal{C}_U)$,

$$- \otimes [z_0 \longrightarrow z_1] : \mathrm{Fun}(\Delta^1, \mathcal{C}_U) \longrightarrow \mathrm{Fun}(\Delta^1, \mathcal{C}_U)$$

preserves L_U-equivalences. Indeed, let

$$\begin{array}{ccc} x_0 & \longrightarrow & y_0 \\ \downarrow & & \downarrow \\ x_1 & \longrightarrow & y_1 \end{array}$$

be an L_U-equivalence, i.e. $x_1/x_0 \longrightarrow y_1/y_0$ is an equivalence in $\mathcal{C}_U$. We have an equivalence

$$(x_1 \times z_1) \,/\, (x_0 \times z_1 \cup_{x_0 \times z_0} x_1 \times z_0) \simeq \left(\frac{x_1 \times z_1}{x_0 \times z_1}\right) / \left(\frac{x_1 \times z_0}{x_0 \times z_0}\right).$$

Using that we have a diagram of pushout squares

$$\begin{array}{ccccc} x_0 \times z_j & \longrightarrow & z_j & \longrightarrow & * \\ \downarrow & & \downarrow & & \downarrow \\ x_1 \times z_j & \longrightarrow & x_1/x_0 \times z_j & \longrightarrow & (x_1 \times z_j)/(x_0 \times z_j) \end{array}$$

(and similarly for y) by cartesian closedness, we deduce that

$$\left(\frac{x_1 \times z_1}{x_0 \times z_1}\right) / \left(\frac{x_1 \times z_0}{x_0 \times z_0}\right) \longrightarrow \left(\frac{y_1 \times z_1}{y_0 \times z_1}\right) / \left(\frac{y_1 \times z_0}{y_0 \times z_0}\right)$$

is an equivalence, as desired.

(2) For a map $f : U \longrightarrow V$ in $\mathcal{T}$,

$$f_{\otimes} : \mathrm{Fun}(\Delta^1, \mathcal{C}_U) \longrightarrow \mathrm{Fun}(\Delta^1, \mathcal{C}_V)$$

sends L_U-equivalences to L_V-equivalences: to show this, suppose

$$\theta : [x_0 \to x_1] \longrightarrow [y_0 \to y_1]$$

is a L_U-equivalence in $\mathrm{Fun}(\Delta^1, \mathcal{C}_U)$. Equivalently, we have a left Kan extension

$$\begin{array}{ccc} \Lambda^2_0 \times \Delta^1 & \longrightarrow & \mathcal{C}_U \\ \downarrow & \nearrow & \\ (\Lambda^2_0)^{\triangleright} \times \Delta^1 & & \end{array}$$

where restriction to the cone point is sent to an equivalence $x_1/x_0 \xrightarrow{\sim} y_1/y_0$. Using distributivity, we get a $\mathcal{T}^{/V}$-left Kan extension diagram

$$\begin{array}{ccc} \prod_f ((\Lambda^2_0 \times \Delta^1) \times (\mathcal{T}^{/U})^{\mathrm{op}}) & \longrightarrow & \prod_f \mathcal{C}_{\underline{U}} \xrightarrow{\prod_f} \mathcal{C}_{\underline{V}} \\ \downarrow & \nearrow & \\ ((\Lambda^2_0)^{\triangleright} \times \Delta^1) \times (\mathcal{T}^{/V})^{\mathrm{op}} & & \end{array}$$

The vertical arrow factors as

$$\prod_f ((\Lambda^2_0 \times \Delta^1) \times (\mathcal{T}^{/U})^{\mathrm{op}}) \longrightarrow (\Lambda^2_0 \times \Delta^1) \times (\mathcal{T}^{/V})^{\mathrm{op}} \longrightarrow ((\Lambda^2_0)^{\triangleright} \times \Delta^1) \times (\mathcal{T}^{/V})^{\mathrm{op}}$$

where the first arrow is induced by the symmetric monoidal structure on $\Delta^1 \times \mathcal{T}^{\mathrm{op}}$. Therefore, the left Kan extension corresponding to $f_\otimes(\theta)$

$$\begin{array}{ccc} \Lambda^2_0 \times \Delta^1 & \longrightarrow & \mathcal{C}_V \\ \downarrow & \nearrow & \\ (\Lambda^2_0)^{\triangleright} \times \Delta^1 & & \end{array}$$

restricts on the cone point to an equivalence, so $f_\otimes(\theta)$ is a L_V-equivalence.

In particular, suppose that $\mathcal{T} = \mathbf{O}_G$ and $\mathcal{C} = \underline{\mathbf{Spc}}_G$. Then we obtain the smash product G-symmetric monoidal structure on pointed G-spaces $\underline{\mathbf{Spc}}_{G,*}$, and given a map of orbits $f : G/H \longrightarrow G/K$ corresponding to an inclusion of subgroups $K \subset H$ and a real K-representation R, the norm functor $f_\otimes$ sends the representation sphere S^R to the representation sphere $S^{\mathbf{Ind}^H_K R}$.

3.3. **Pointwise $\mathcal{O}$-monoidal structure.** In this brief subsection, we indicate how to adapt the construct of the $\mathcal{T}$-Day convolution so as to construct the cotensor of $\mathbf{Op}_{\mathcal{O},\mathcal{T}}$ over $\mathbf{Cat}_{\mathcal{T}}$. In other words, given a fibration of $\mathcal{T}$-∞-operads $p : \mathcal{D}^\otimes \longrightarrow \mathcal{O}^\otimes$ and a $\mathcal{T}$-∞-category $\mathcal{K}$, we have a $\mathcal{T}$-∞-operad $\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{K} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{O}, \mathcal{D})^\otimes$ that satisfies the universal mapping property

$$\mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{K} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{O}, \mathcal{D})) \simeq \mathrm{Fun}_{\mathcal{T}}(\mathcal{K}, \underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{D})) \tag{3.3.1}$$

for all fibrations of ∞-operads $q : \mathcal{C}^\otimes \longrightarrow \mathcal{O}^\otimes$.

For the following construction, observe the isomorphism

$$\mathrm{Ar}^{ne}(\mathcal{O}^\otimes) \times_{\mathrm{ev}_1, \mathcal{O}^\otimes, \mathrm{pr}} (\mathcal{O}^\otimes \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{K}) \cong \mathrm{Ar}^{ne}(\mathcal{O}^\otimes) \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{K}.$$

3.3.1. **Theorem-Construction.** Let $\mathcal{O}^\otimes$ be a $\mathcal{T}$-∞-operad and $\mathcal{K}$ a $\mathcal{T}$-∞-category. Consider the span diagram of marked simplicial sets

$$(\mathcal{O}^\otimes, \mathrm{Ne}) \xleftarrow{\mathrm{ev}_0} (\mathrm{Ar}^{ne}(\mathcal{O}^\otimes) \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{K}, \mathrm{Ne}) \xrightarrow{\mathrm{ev}_1} (\mathcal{O}^\otimes, \mathrm{Ne}).$$

where by the middle marking Ne we mean those edges whose source and target in $\mathcal{O}^\otimes$ are inert and whose projection to $\mathcal{K}$ is a cocartesian edge. Then the functor

$$(\mathrm{ev}_0)_* \circ (\mathrm{ev}_1)^* : \mathbf{sSet}^+_{/(\mathcal{O}^\otimes, \mathrm{Ne})} \longrightarrow \mathbf{sSet}^+_{/(\mathcal{O}^\otimes, \mathrm{Ne})}$$

is right Quillen with respect to the $\mathcal{T}$-operadic model structures. For a fibration of ∞-operads $p : \mathcal{C}^\otimes \longrightarrow \mathcal{O}^\otimes$, we let

$$\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{K} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{O}, \mathcal{C})^\otimes := (\mathrm{ev}_0)_*(\mathrm{ev}_1)^*(\mathcal{C}^\otimes, \mathrm{Ne}).$$

If $\mathcal{O} \simeq \mathcal{T}^{\mathrm{op}}$, then we more simply write

$$\underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K}, \mathcal{C})^\otimes := (\mathrm{ev}_0)_*(\mathrm{ev}_1)^*(\mathcal{C}^\otimes, \mathrm{Ne}).$$

This construction satisfies the universal property (3.3.1) and its underlying $\mathcal{T}$-∞-category is as the notation indicates.

Proof. This follows along the same lines as our proofs of the analogous results for $\mathcal{T}$-Day convolution in Section 3.1. ☐

3.3.2. **Remark.** In the situation of Theorem-Construction 3.3.1, a fibrant replacement of $(\mathcal{O}^{\otimes}, \mathrm{Ne}) \times_{\mathcal{T}^{op}} {}_{\natural}\mathcal{K}$ in the $\mathcal{T}$-operadic model structure on $\mathbf{sSet}^{+}_{/(\mathcal{O}^{\otimes},\mathrm{Ne})}$ computes the *tensor* of $\mathbf{Op}_{\mathcal{O},\mathcal{T}}$ over $\mathbf{Cat}_{\mathcal{T}}$.

If we then suppose that $\mathcal{C}^{\otimes}$ is an $\mathcal{O}$-monoidal $\mathcal{T}$-∞-category, we obtain the *pointwise* $\mathcal{O}$-monoidal structure on $\underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K}, \mathcal{C})$. In contrast to the $\mathcal{T}$-Day convolution, we don't need to impose any further hypotheses on $\mathcal{C}^{\otimes}$ for this to exist.

3.3.3. **Theorem-Construction.** Let $\mathcal{O}^{\otimes}$ be a $\mathcal{T}$-∞-operad and $\mathcal{K}$ a $\mathcal{T}$-∞-category. Consider the span diagram of marked simplicial sets

$$(\mathcal{O}^{\otimes})^{\sharp} \xleftarrow{\mathrm{ev}_0} \mathrm{Ar}^{ne}(\mathcal{O}^{\otimes})^{\sharp} \times_{\mathcal{T}^{op}} {}_{\natural}\mathcal{K} \xrightarrow{\mathrm{ev}_1} (\mathcal{O}^{\otimes})^{\sharp}.$$

Then the functor

$$(\mathrm{ev}_0)_* \circ (\mathrm{ev}_1)^* : \mathbf{sSet}^{+}_{/\mathcal{O}^{\otimes}} \longrightarrow \mathbf{sSet}^{+}_{/\mathcal{O}^{\otimes}}$$

agrees with the construction of Theorem-Construction 3.3.1 on underlying simplicial sets and is right Quillen with respect to the $\mathcal{T}$-monoidal model structures. Given any $\mathcal{O}$-monoidal $\mathcal{T}$-∞-categories $\mathcal{C}^{\otimes}, \mathcal{D}^{\otimes}$, we then have a natural equivalence

$$\mathrm{Fun}^{\otimes}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{K} \times_{\mathcal{T}^{op}} \mathcal{O}, \mathcal{D})) \simeq \mathrm{Fun}_{\mathcal{T}}(\mathcal{K}, \underline{\mathrm{Fun}}^{\otimes}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{D})).$$

Proof. That $(\mathrm{ev}_0)_* \circ (\mathrm{ev}_1)^*$ is right Quillen follows by [Lur17, Thm. B.4.2] as in the proof of Theorem 3.1.4. The only differences to note are regarding conditions (4) and (7). For (4), by [Sha21b, Prop. 3.5(1)] the ev_0-cartesian edges in $\mathrm{Ar}^{ne}(\mathcal{O}^{\otimes})$ are fiberwise active in the target, hence $\mathrm{ev}_0 : \mathrm{Ar}^{ne}(\mathcal{O}^{\otimes}) \times_{\mathcal{T}^{op}} \mathcal{K} \longrightarrow \mathcal{O}^{\otimes}$ is a cartesian fibration whose cartesian edges project to equivalences in $\mathcal{K}$. (7) then follows by inspection.

The universal mapping property then follows by restricting the equivalence (3.3.1). ☐

3.3.4. **Example.** Suppose $\mathcal{O}^{\otimes} = \underline{\mathbf{F}}_{\mathcal{T},*}$, let $\mathcal{C}^{\otimes}$ be a $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-category, and let $\mathcal{K}$ be a $\mathcal{T}$-∞-category. Then we may unwind the pointwise $\mathcal{T}$-symmetric monoidal structure on $\underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K}, \mathcal{C})$ as follows:

(∗) Let $f : U \longrightarrow V$ be a map of finite $\mathcal{T}$-sets. Then the norm functor

$$f_{\otimes} : \mathrm{Fun}_{\mathcal{T}^{/U}}(\mathcal{K}_{\underline{U}}, \mathcal{C}_{\underline{U}}) \longrightarrow \mathrm{Fun}_{\mathcal{T}^{/V}}(\mathcal{K}_{\underline{V}}, \mathcal{C}_{\underline{V}})$$

sends a $\mathcal{T}^{/U}$-functor $F : \mathcal{K}_{\underline{U}} \longrightarrow \mathcal{C}_{\underline{U}}$ to the $\mathcal{T}^{/V}$-functor

$$\mathcal{K}_{\underline{V}} \xrightarrow{\eta} \prod_f \mathcal{K}_{\underline{U}} \simeq \mathrm{Fun}_{\mathcal{T}^{/V}}(\underline{U}, \mathcal{K}_{\underline{V}}) \xrightarrow{\prod_f F} \prod_f \mathcal{C}_{\underline{U}} \simeq \mathrm{Fun}_{\mathcal{T}^{/V}}(\underline{U}, \mathcal{C}_{\underline{V}}) \xrightarrow{f_{\otimes}} \mathcal{C}_{\underline{V}}$$

where η is the diagonal $\mathcal{T}^{/V}$-functor (i.e., the unit of the restriction-coinduction adjunction) and the norm $\mathcal{T}^{/V}$-functor $f_{\otimes}$ is defined as in Example 2.3.5.

In particular, note that if $\mathcal{C}^{\otimes}$ is distributive, then $\underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{K}, \mathcal{C})^{\otimes}$ is also distributive.

4. Parametrized operadic left Kan extensions

In this section, we construct $\mathcal{T}$-operadic left Kan extensions, implementing in the operadic context the strategy that the second author used to construct $\mathcal{T}$-left Kan extensions in [Sha21a, §§9-10].

4.0.1. **Remark.** The strategy of our construction of $\mathcal{T}$-operadic left Kan extensions will be to first show that the $\mathcal{T}$-colimit of a lax $\mathcal{O}$-monoidal functor canonically inherits a $\mathcal{O}$-algebra structure, and to then reduce to this case via the $\mathcal{O}$-monoidal envelope. If we let $\mathcal{T} = \Delta^0$, this gives a new construction of Lurie's operadic left Kan extension ([Lur17, §3.1.2]). See also [CH21].

We first begin with some necessary preliminaries on generalized $\mathcal{T}$-∞-operads and the $\mathcal{T}$-operadic join.

4.1. **Generalized $\mathcal{T}$-∞-operads.** Given a map of finite $\mathcal{T}$-sets $\phi : U \longrightarrow V$, let σ_1, σ_2 be two squares in $\mathbf{F}_{\mathcal{T}}$

$$\begin{array}{ccc} U_i & \xrightarrow{\alpha_i} & U \\ \downarrow{\scriptstyle \phi_i} & & \downarrow{\scriptstyle \phi} \\ V_i & \xrightarrow{\beta_i} & V \end{array}$$

such that α_i is a summand inclusion, the induced map $U_i \longrightarrow V_i \times_V U$ is also a summand inclusion, and moreover $(\alpha_1, \alpha_2) : U_1 \sqcup U_2 \longrightarrow U$ is an epimorphism. Let $U_{12} = U_1 \times_U U_2$ and $V_{12} = V_1 \times_V V_2$. Then we have an induced map

$$g_{\phi,\sigma_1,\sigma_2} : (\Lambda^2_2)^{\lhd} \longrightarrow \underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*}$$

which selects the square

$$\begin{array}{ccc} [U_+ \to V] & \longrightarrow & [(U_1)_+ \to V_1] \\ \downarrow & & \downarrow \\ [(U_2)_+ \to V_2] & \longrightarrow & [(U_{12})_+ \to V_{12}] \end{array}$$

in which every morphism is inert.

We define the *generalized* $\mathcal{T}$*-operadic model structure* on $\mathbf{sSet}^+_{/(\underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*},\mathrm{Ne})}$ to be the model structure defined using the categorical pattern $(\mathrm{Ne}, \mathrm{All}, \{g_{\phi,\sigma_1,\sigma_2}\})$ on $\underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*}$, letting the ϕ and $\{\sigma_1, \sigma_2\}$ range over all possible choices. We call the fibrant objects for this model structure *generalized* $\mathcal{T}$-∞*-operads*. Note that $\mathcal{T}$-∞-operads are fibrant in this model structure, so are examples of generalized $\mathcal{T}$-∞-operads. However, the converse is not true. Indeed, let $\sigma_0 : \mathbf{F}^{\mathrm{op}}_{\mathcal{T}} \longrightarrow \underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*}$ be the cocartesian section which selects $[\emptyset_+ \to V]$ in each fiber and define $\widetilde{\mathcal{C}}_0 := \mathbf{F}^{\mathrm{op}}_{\mathcal{T}} \times_{\sigma_0, \underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*}} \widetilde{\mathcal{C}}^{\otimes}$. Then if $\widetilde{\mathcal{C}}^{\otimes} \longrightarrow \underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*}$ is a generalized $\mathcal{T}$-∞-operad, $\widetilde{\mathcal{C}}_0$ is not necessarily the terminal $\mathcal{T}$-∞-category.

We then say that $\mathcal{C}^{\otimes} \longrightarrow \underline{\mathbf{F}}_{\mathcal{T},*}$ is a *generalized* $\mathcal{T}$-∞*-operad* if it is the pullback of a generalized $\mathcal{T}$-∞-operad $\widetilde{\mathcal{C}}^{\otimes} \longrightarrow \underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*}$ under the inclusion $\underline{\mathbf{F}}_{\mathcal{T},*} \longrightarrow \underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*}$. Let $\mathcal{C}_0$ be the corresponding pullback of $\widetilde{\mathcal{C}}_0$. The $\mathcal{T}$-functor $\mathcal{T}^{\mathrm{op}} \times \Delta^1 \longrightarrow \underline{\mathbf{F}}_{\mathcal{T},*}$ which selects the inert edge $[V_+ \to V] \longrightarrow [\emptyset_+ \to V]$ in each fiber induces a $\mathcal{T}$-functor $\mathcal{C} \longrightarrow \mathcal{C}_0$.

4.1.1. **Lemma.** *Suppose $\mathcal{C}^{\otimes} \longrightarrow \underline{\mathbf{F}}_{\mathcal{T},*}$ is a generalized $\mathcal{T}$-∞-operad. Let $f : U \longrightarrow V$ be a morphism in $\mathbf{F}_{\mathcal{T}}$ and suppose that we have an orbit decomposition $U \simeq \sqcup_{1 \leq i \leq n} U_i$. Abbreviate $U_i \times_V U_j$ as U_{ij} and let $f_i : U_i \longrightarrow V$, $f_{ij} : U_{ij} \longrightarrow V$ denote the induced maps. Then we have an equivalence of $\mathcal{T}^{/V}$-∞-categories*

$$\underline{\mathcal{C}^{\otimes}_{[U_+ \to V]}} \longrightarrow \prod_{f_1} \mathcal{C}_{\underline{U_1}} \underset{\prod_{f_{12}} (\mathcal{C}_0)_{\underline{U_{12}}}}{\times} \prod_{f_2} \mathcal{C}_{\underline{U_2}} \underset{\prod_{f_{23}} (\mathcal{C}_0)_{\underline{U_{23}}}}{\times} \cdots \underset{\prod_{f_{(n-1)n}} (\mathcal{C}_0)_{\underline{U_{(n-1)n}}}}{\times} \prod_{f_n} \mathcal{C}_{\underline{U_n}}$$

Proof. Note that U_{ij} need not be an orbit, so the notation $(\mathcal{C}_0)_{\underline{U_{ij}}}$ means $\coprod_{\mathcal{O} \subset U_{ij}} (\mathcal{C}_0)_{\underline{\mathcal{O}}} \longrightarrow \underline{U_{ij}}$ for any orbit decomposition of U_{ij}. Without loss of generality we may suppose $n = 2$. We have a pullback square in $\mathbf{F}_{\mathcal{T}}$

$$\begin{array}{ccc} U_{12} & \xrightarrow{g_2} & U_1 \\ \downarrow{\scriptstyle g_1} & & \downarrow{\scriptstyle f_1} \\ U_2 & \xrightarrow{f_2} & V. \end{array}$$

The unit maps for the restriction-coinduction adjunction yield $\mathcal{T}^{/V}$-functors

$$\prod_{f_1} \mathcal{C}_{\underline{U_1}} \longrightarrow \prod_{f_{12}} \mathcal{C}_{\underline{U_{12}}} \longleftarrow \prod_{f_1} \mathcal{C}_{\underline{U_1}}$$

and postcomposing with

$$\prod_{f_{12}} \mathcal{C}_{\underline{U_{12}}} \longrightarrow \prod_{f_{12}} (\mathcal{C}_0)_{\underline{U_{12}}}$$

we obtain the $\mathcal{T}^{/V}$-functors which define the pullback. Using the 'fiberwise' definition of generalized $\mathcal{T}$-∞-operad, we can use the same argument as in the proof of Theorem 2.3.3 to accomplish the proof. $\square$

4.2. $\mathcal{T}$-operadic join.

4.2.1. **Definition.** Let $\widetilde{\mathcal{C}}^\otimes, \widetilde{\mathcal{D}}^\otimes, \widetilde{\mathcal{O}}^\otimes$ be generalized $\mathcal{T}$-∞-operads over $\underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*}$ and let $p, q : \widetilde{\mathcal{C}}^\otimes, \widetilde{\mathcal{D}}^\otimes \longrightarrow \widetilde{\mathcal{O}}^\otimes$ be categorical fibrations preserving the inert edges. Then the $\mathcal{T}$-*operadic join* of p and q is defined to be

$$\widetilde{(\mathcal{C} \star_{\mathcal{O}} \mathcal{D})}^\otimes := \widetilde{\mathcal{C}}^\otimes \star_{\widetilde{\mathcal{O}}^\otimes} \widetilde{\mathcal{D}}^\otimes \longrightarrow \widetilde{\mathcal{O}}^\otimes.$$

Similarly, given $\mathcal{C}^\otimes, \mathcal{D}^\otimes \longrightarrow \mathcal{O}^\otimes$ fibrations of generalized $\mathcal{T}$-∞-operads over $\underline{\mathbf{F}}_{\mathcal{T},*}$, we define the $\mathcal{T}$-operadic join $(\mathcal{C} \star_{\mathcal{O}} \mathcal{D})^\otimes$ to be $\mathcal{C}^\otimes \star_{\mathcal{O}^\otimes} \mathcal{D}^\otimes \longrightarrow \mathcal{O}^\otimes$.

Note that the underlying $\mathcal{T}$-∞-category of a $\mathcal{T}$-operadic join $(\mathcal{C} \star_{\mathcal{O}} \mathcal{D})^\otimes$ is the $\mathcal{O}$-join of the underlying $\mathcal{T}$-∞-categories of the factors (by the base-change property [Sha21a, Lem. 4.4]).

4.2.2. **Proposition.** $\widetilde{(\mathcal{C} \star_{\mathcal{O}} \mathcal{D})}^\otimes$ *is a generalized* $\mathcal{T}$-∞-*operad and the structure map to* $\widetilde{\mathcal{O}}^\otimes$ *is a fibration of generalized* $\mathcal{T}$-∞-*operads.*

Proof. By the proof of [Sha21a, Prop. 4.7(2)], $\pi : \widetilde{(\mathcal{C} \star_{\mathcal{O}} \mathcal{D})}^\otimes \longrightarrow \underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*}$ admits cocartesian lifts over the inert edges. Moreover, an edge $\Delta^1 \longrightarrow \widetilde{(\mathcal{C} \star_{\mathcal{O}} \mathcal{D})}^\otimes$ is π-cocartesian if and only if it factors through either $\widetilde{\mathcal{C}}^\otimes$ or $\widetilde{\mathcal{D}}^\otimes$ and is inert there.

The fiber of $\widetilde{(\mathcal{C} \star_{\mathcal{O}} \mathcal{D})}^\otimes$ over an object $[U_+ \to V]$ of $\underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*}$ is given by $\widetilde{\mathcal{C}}^\otimes_{[U_+ \to V]} \star_{\widetilde{\mathcal{O}}^\otimes_{[U_+ \to V]}} \widetilde{\mathcal{D}}^\otimes_{[U_+ \to V]}$. Moreover, the relative join is functorial in the following sense: given commutative diagrams

$$\begin{array}{ccc} X & \longrightarrow & X' \\ \downarrow & & \downarrow \\ B & \longrightarrow & B' \end{array}, \quad \begin{array}{ccc} Y & \longrightarrow & Y' \\ \downarrow & & \downarrow \\ B & \longrightarrow & B' \end{array}$$

we have an induced map $X \star_B Y \longrightarrow X' \star_{B'} Y'$ covering $B \times \Delta^1 \longrightarrow B' \times \Delta^1$. From our explicit description of the π-cocartesian edges, we see that the Segal maps for $\widetilde{(\mathcal{C} \star_{\mathcal{O}} \mathcal{D})}^\otimes$ are obtained in this way. Consequently, it is clear that they are equivalences.

It remains to check that for all of the defining maps $g_{\phi,\sigma_1,\sigma_2} : (\Lambda^2_2)^\triangleleft \longrightarrow \underline{\mathbf{F}}^{\mathrm{big}}_{\mathcal{T},*}$, we have that for every lift $G : (\Lambda^2_2)^\triangleleft \longrightarrow \widetilde{(\mathcal{C} \star_{\mathcal{O}} \mathcal{D})}^\otimes$ where all edges are sent to π-cocartesian edges, G is a π-limit diagram. For this, there are two cases to consider. Either G factors through $\widetilde{\mathcal{C}}^\otimes$, in which case the assertion obviously follows from G being a $\pi|_{\widetilde{\mathcal{C}}^\otimes}$-limit diagram, or G factors through $\widetilde{\mathcal{D}}^\otimes$, in which case the assertion is a consequence of Lemma 4.2.3.

Finally, the second assertion is obvious given the first. ☐

4.2.3. **Lemma.** *Let K, X, Y and B be ∞-categories, let $f_1, f_2 : X, Y \longrightarrow B$ be categorical fibrations and let $p : K \longrightarrow Y$ be a functor. Also let p denote the composition $K \xrightarrow{p} Y \subset X \star_B Y$. Then we have an equivalence of ∞-categories over $B^{/f_2 p} \times \Delta^1$*

$$(X \star_B Y)^{/p} \simeq (X \times_B B^{/f_2 p}) \star_{B^{/f_2 p}} Y^{/p}.$$

Consequently, if $\overline{p} : K^\triangleleft \longrightarrow Y$ is a f_2-limit diagram, then $\overline{p} : K^\triangleleft \longrightarrow Y \subset X \star_B Y$ is a f-limit diagram (where f denotes the structure map $X \star_B Y \longrightarrow B$).

Proof. Let q denote $K \longrightarrow X \star_B Y \longrightarrow B \times \Delta^1$ and note that q factors as $K \xrightarrow{f_2 p} B \times \{1\} \subset B \times \Delta^1$. We first place $(X \star_B Y)^{/p}$ into the diagram of pullback squares

$$\begin{array}{ccccc} (X \star_B Y)^{/p} & \longrightarrow & Z & \longrightarrow & \mathrm{Fun}(K^\triangleleft, X \star_B Y) \\ \downarrow & & \downarrow & & \downarrow \\ \{p\} & \longrightarrow & \mathrm{Fun}_{/B}(K, Y) & \longrightarrow & \mathrm{Fun}(K, X \star_B Y) \\ & & \downarrow & & \downarrow \\ & & \{q\} & \longrightarrow & \mathrm{Fun}(K, B \times \Delta^1). \end{array}$$

In addition, using that the composition $\mathrm{Fun}(K^{\triangleleft}, X \star_B Y) \longrightarrow \mathrm{Fun}(K, X \star_B Y) \longrightarrow \mathrm{Fun}(K, B \times \Delta^1)$ agrees with $\mathrm{Fun}(K^{\triangleleft}, X \star_B Y) \longrightarrow \mathrm{Fun}(K^{\triangleleft}, B \times \Delta^1) \longrightarrow \mathrm{Fun}(K, B \times \Delta^1)$, Z fits into the diagram of pullback squares

$$\begin{array}{ccc}
Z & \longrightarrow & \mathrm{Fun}(K^{\triangleleft}, X \star_B Y) \\
\downarrow & & \downarrow \\
(B \times \Delta^1)^{/q} & \longrightarrow & \mathrm{Fun}(K^{\triangleleft}, B \times \Delta^1) \cong \mathrm{Fun}(K^{\triangleleft}, B) \times \mathrm{Fun}(K^{\triangleleft}, \Delta^1) \\
\downarrow & & \downarrow \\
\{q\} = \{f_2 p\} \times \{\mathrm{const}_1\} & \longrightarrow & \mathrm{Fun}(K, B \times \Delta^1) \cong \mathrm{Fun}(K, B) \times \mathrm{Fun}(K, \Delta^1).
\end{array}$$

Because $(\Delta^1)^{/\mathrm{const}_1} \simeq \Delta^1$, we get that $(B \times \Delta^1)^{/q} \simeq B^{/f_2 p} \times \Delta^1$. Consequently,

$$(X \star_B Y)^{/p} \simeq \{p\} \times_{\mathrm{Fun}_{/B}(K,Y)} \left(\mathrm{Fun}(K^{\triangleleft}, X \star_B Y) \times_{\mathrm{Fun}(K^{\triangleleft}, B \times \Delta^1)} B^{/f_2 p} \times \Delta^1 \right).$$

Let $A \longrightarrow B^{/f_2 p} \times \Delta^1$ be any functor. We will identify $\mathrm{Fun}_{/(B^{/f_2 p} \times \Delta^1)}(A, (X \star_B Y)^{/p})$ with $\mathrm{Fun}_{/B}(A_0, X) \times \mathrm{Fun}_{/(B^{/f_2 p})}(A_1, Y^{/p})$ and thereby prove the claim. Let

$$A \times K^{\triangleleft} \longrightarrow B^{/f_2 p} \times \Delta^1 \times K^{\triangleleft} \longrightarrow B \times \Delta^1$$

be the composite of the given map and the map adjoint to $B^{/f_2 p} \times \Delta^1 \longrightarrow \mathrm{Fun}(K^{\triangleleft}, B \times \Delta^1)$. Note that $(A \times K^{\triangleleft})_0 \cong A_0$ and $(A \times K^{\triangleleft})_1 \cong (A \times K) \cup_{A_1 \times K} A_1 \times K^{\triangleleft}$. We then have the chain of equivalences

$$\begin{aligned}
\mathrm{Fun}_{/(B^{/f_2 p} \times \Delta^1)}(A, (X \star_B Y)^{/p}) &\simeq \{p \circ \mathrm{pr}_K\} \times_{\mathrm{Fun}(A \times K, X \star_B Y)} \mathrm{Fun}_{/(B \times \Delta^1)}(A \times K^{\triangleleft}, X \star_B Y) \\
&\simeq \{p \circ \mathrm{pr}_K\} \times_{\mathrm{Fun}(A \times K, X \star_B Y)} (\mathrm{Fun}_{/B}(A_0, X) \times \mathrm{Fun}_{/B}((A \times K) \cup_{A_1 \times K} A_1 \times K^{\triangleleft}, Y)) \\
&\simeq \mathrm{Fun}_{/B}(A_0, X) \times \left(\{p \circ \mathrm{pr}_K\} \underset{\mathrm{Fun}_{/B}(A \times K, Y)}{\times} \mathrm{Fun}_{/B}(A \times K, Y) \underset{\mathrm{Fun}_{/B}(A_1 \times K, Y)}{\times} \mathrm{Fun}_{/B}(A_1 \times K^{\triangleleft}, Y) \right) \\
&\simeq \mathrm{Fun}_{/B}(A_0, X) \times \left(\{p \circ \mathrm{pr}_K\} \underset{\mathrm{Fun}_{/B}(A_1 \times K, Y)}{\times} \mathrm{Fun}_{/B}(A_1 \times K^{\triangleleft}, Y) \right)
\end{aligned}$$

and finally

$$\{p \circ \mathrm{pr}_K\} \underset{\mathrm{Fun}_{/B}(A_1 \times K, Y)}{\times} \mathrm{Fun}_{/B}(A_1 \times K^{\triangleleft}, Y) \simeq \mathrm{Fun}_{/(B^{/f_2 p})}(A_1, Y^{/p})$$

because both sides compute the total fiber of the punctured cube

$$\begin{array}{ccccc}
 & & & & \mathrm{Fun}(A_1 \times K^{\triangleleft}, Y) \\
 & & & \swarrow & \downarrow \\
\Delta^0 & \longrightarrow & \mathrm{Fun}(A_1 \times K, Y) & & \\
\downarrow & & \downarrow & & \\
 & \Delta^0 & \longrightarrow & & \mathrm{Fun}(A_1 \times K^{\triangleleft}, B) \\
 & \swarrow & \downarrow & \swarrow & \\
\Delta^0 & \longrightarrow & \mathrm{Fun}(A_1 \times K, B) & &
\end{array}$$

For the last assertion, we need to show that

$$\begin{array}{ccc}
(X \star_B Y)^{/\overline{p}} & \longrightarrow & (X \star_B Y)^{/p} \\
\downarrow & & \downarrow \\
B^{/f\overline{p}} & \longrightarrow & B^{/fp}
\end{array}$$

is a homotopy pullback square. But by the first part of the lemma this is equivalent to

$$\begin{array}{ccc} (X \times_B B^{/f\overline{p}}) \star_{B^{/f\overline{p}}} Y^{/\overline{p}} & \longrightarrow & (X \times_B B^{/fp}) \star_{B^{/fp}} Y^{/p} \\ \downarrow & & \downarrow \\ B^{/f\overline{p}} & \longrightarrow & B^{/fp}. \end{array}$$

One easily deduces that this is a homotopy pullback square as a consequence of the two squares

$$\begin{array}{ccc} X \times_B B^{/f\overline{p}} & \longrightarrow & X \times_B B^{/fp} \\ \downarrow & & \downarrow \\ B^{/f\overline{p}} & \longrightarrow & B^{/fp} \end{array} \quad , \quad \begin{array}{ccc} Y^{/\overline{p}} & \longrightarrow & Y^{/p} \\ \downarrow & & \downarrow \\ B^{/f\overline{p}} & \longrightarrow & B^{/fp} \end{array}$$

being homotopy pullback squares (the second by our hypothesis). □

4.3. **Construction of $\mathcal{T}$-operadic left Kan extensions.** We now turn towards constructing $\mathcal{T}$-operadic left Kan extensions. We will need a variant of the $\mathcal{T}$-Day convolution for our proofs, where we allow the source $\mathcal{T}$-∞-operad to be generalized.

4.3.1. **Variant.** Suppose that $\mathcal{C}^\otimes$ is a generalized $\mathcal{T}$-∞-operad. Then the proofs of Theorem 3.1.4 and Corollary 3.1.5 still go through to show that

$$\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C},\mathcal{E})^\otimes \longrightarrow \mathcal{O}^\otimes$$

is a (non-generalized) $\mathcal{T}$-∞-operad. Moreover, if $\mathcal{C}^\otimes, \mathcal{E}^\otimes \longrightarrow \mathcal{O}^\otimes$ are cocartesian fibrations, then the proof of Proposition 3.2.2 goes through to show that $\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C},\mathcal{E})^\otimes \longrightarrow \mathcal{O}^\otimes$ is a locally cocartesian fibration. However, the proof of Theorem 3.2.6 doesn't directly apply because if $\mathcal{C}^\otimes$ is generalized, we have a different formula for $\mathcal{C}^\otimes_{\underline{x}}$ involving fiber products instead of products (cf. Lemma 4.1.1).

For the following results, let $\mathcal{O}^\otimes$ be a $\mathcal{T}$-∞-operad, $p : \mathcal{C}^\otimes \longrightarrow \mathcal{O}^\otimes$ an $\mathcal{O}$-monoidal $\mathcal{T}$-∞-category and $q : \mathcal{E}^\otimes \longrightarrow \mathcal{O}^\otimes$ a distributive $\mathcal{O}$-monoidal $\mathcal{T}$-∞-category.

4.3.2. **Lemma.** *Consider the commutative diagram*

$$\begin{array}{ccc} \widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C} \star_{\mathcal{O}} \mathcal{O}, \mathcal{E})^\otimes & \xrightarrow{\rho} & \mathcal{E}^\otimes \\ \downarrow{\scriptstyle\lambda} & & \downarrow{\scriptstyle q} \\ \widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C},\mathcal{E})^\otimes & \xrightarrow{\pi} & \mathcal{O}^\otimes. \end{array}$$

where λ is given by restriction along $\mathcal{C}^\otimes \subset (\mathcal{C} \star_{\mathcal{O}} \mathcal{O})^\otimes$, ρ is given by restriction along $\mathcal{O}^\otimes \subset (\mathcal{C} \star_{\mathcal{O}} \mathcal{O})^\otimes$ followed by the equivalence $\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{O},\mathcal{E})^\otimes \xrightarrow{\simeq} \mathcal{E}^\otimes$ induced by precomposition with the identity section $\iota : \mathcal{O}^\otimes \longrightarrow \mathrm{Ar}^{ne}(\mathcal{O}^\otimes)$ (cf. Proposition 3.1.7), and π is the structure map.

1. *An edge e in $\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C} \star_{\mathcal{O}} \mathcal{O}, \mathcal{E})^\otimes$ is locally $\pi\lambda$-cocartesian if and only if $\lambda(e)$ is locally π-cocartesian and $\rho(e)$ is locally q-cocartesian. Consequently, $\pi\lambda$ is cocartesian.*
2. *λ is $\mathcal{O}^\otimes$-cartesian and ρ is cocartesian.*

Proof. (1): ρ and λ are fibrations of $\mathcal{T}$-∞-operads by the functoriality of the Day convolution, hence preserve inert edges. By Lemma 3.2.1, it suffices to consider a locally $\pi\lambda$-cocartesian edge e over a fiberwise active edge $f : U \longrightarrow V \in \mathbf{F}_{\mathcal{T}}$ (identified with $[U_+ \to V] \longrightarrow [V_+ \to V]$ in $\underline{\mathbf{F}}_{\mathcal{T},*}$). Suppose e covers $\alpha : x \longrightarrow y$ in $\mathcal{O}^\otimes_V$. Then by Proposition 3.2.2(3), e corresponds to a $\mathcal{T}^{/V}$-left Kan extension

$$\begin{array}{ccccc} (\mathcal{C}^\otimes_{\underline{x}})^{\trianglerighteq} & \xrightarrow{F} & \mathcal{E}^\otimes_{\underline{x}} & \xrightarrow{\alpha_\otimes} & \mathcal{E}_{\underline{y}} \\ \downarrow{\scriptstyle (\alpha_\otimes)^{\trianglerighteq}} & \Downarrow & & \nearrow{\scriptstyle G} & \downarrow \\ (\mathcal{C}_{\underline{y}})^{\trianglerighteq} & & \longrightarrow & & (\mathcal{T}^{/V})^{\mathrm{op}}. \end{array}$$

Examining the pointwise formula defining $\mathcal{T}^{/V}$-left Kan extensions, we see that G is a $\mathcal{T}^{/V}$-left Kan extension of $\alpha_\otimes \circ F$ along $\alpha_\otimes \star \mathrm{id}$ if and only if $G|_{\mathcal{C}_{\underline{y}}}$ is a $\mathcal{T}^{/V}$-left Kan extension of $\alpha_\otimes \circ F|_{\mathcal{C}^\otimes_{\underline{x}}}$ along $\alpha_\otimes$ and $G|_{\underline{V}} \simeq \alpha_\otimes \circ F|_{\underline{V}}$

(for the latter, using that the inclusion of the right $\mathcal{T}$-cone point is fiberwise cofinal and [Sha21a, Thm. 6.7]). This implies the first part of the claim. For the consequence, we only need to check that the composition of locally cocartesian edges is again locally cocartesian, and this is clear using the claim and Theorem 3.2.6.

(2): Taking the fiber over an object $y \in \mathcal{O}_V$, we get a bifibration

$$\mathrm{Fun}_{\mathcal{T}^{/V}}((\mathcal{C}_{\underline{y}})^{\underline{\triangleright}}, \mathcal{E}_{\underline{y}}) \longrightarrow \mathrm{Fun}_{\mathcal{T}^{/V}}(\mathcal{C}_{\underline{y}}, \mathcal{E}_{\underline{y}}) \times \mathcal{E}_{\underline{y}}.$$

Combining this observation with the product decomposition over a general object $x \in \mathcal{O}^{\otimes}$ obtained by the $\mathcal{T}$-Segal condition, we deduce that λ is fiberwise cartesian and ρ is fiberwise cocartesian (over $\mathcal{O}^{\otimes}$). It remains to show that for λ the cocartesian pushforward of fiberwise cartesian edges remain fiberwise cartesian, and the dual statement for ρ. This is obvious over inert edges, so it suffices to consider a fiberwise active edge $\alpha : x \longrightarrow y$ in $\mathcal{O}^{\otimes}_V$. Also, without loss of generality suppose $y \in \mathcal{O}_V$. Let $\theta : F_0 \longrightarrow F_1$ be an edge in $\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{E})^{\otimes}_x$, which corresponds to a natural transformation

$$\theta : \Delta^1 \times \mathcal{C}^{\otimes}_{\underline{x}} \longrightarrow \mathcal{E}^{\otimes}_{\underline{x}}.$$

A fiberwise cartesian edge in $\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C} \star_{\mathcal{O}} \mathcal{O}, \mathcal{E})^{\otimes}_x$ over θ is given by

$$\theta' : \Delta^1 \times (\mathcal{C}^{\otimes}_{\underline{x}})^{\underline{\triangleright}} \longrightarrow \mathcal{E}^{\otimes}_{\underline{x}}$$

which restricts to θ and is a constant natural transformation when restricted to the right $\mathcal{T}$-cone point. The cocartesian pushforward $\alpha_! \theta'$ is given by the $\mathcal{T}^{/V}$-left Kan extension of $\alpha_{\otimes} \circ \theta'$ along $\mathrm{id} \times \alpha_{\otimes}$. Clearly, this is still a constant natural transformation when restricted to the right $\mathcal{T}$-cone point, which proves that $\alpha_! \theta'$ is a fiberwise cartesian edge lifting $\alpha_! \theta$. A similar argument handles the fiberwise cocartesian edges. □

The next proposition is a very general and parametrized form of the following observation: the colimit of a lax symmetric monoidal functor canonically inherits the structure of a commutative algebra.

4.3.3. **Proposition.** *Let $F : \mathcal{C}^{\otimes} \longrightarrow \mathcal{E}^{\otimes}$ be a lax $\mathcal{O}$-monoidal $\mathcal{T}$-functor and let $\sigma_F : \mathcal{O}^{\otimes} \longrightarrow \widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{E})^{\otimes}$ be the associated section (which is an $\mathcal{O}$-algebra map). Then there exists a $\mathcal{O}$-algebra lift of σ_F to*

$$\sigma_{\overline{F}} : \mathcal{O}^{\otimes} \longrightarrow \widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C} \star_{\mathcal{O}} \mathcal{O}, \mathcal{E})^{\otimes}$$

such that the resulting $\mathcal{O}$-algebra

$$A = \overline{F}|_{\mathcal{O}^{\otimes}} : \mathcal{O}^{\otimes} \longrightarrow \mathcal{E}^{\otimes}$$

has underlying section $A|_{\mathcal{O}} : \mathcal{O} \longrightarrow \mathcal{E}$ computed as the $q|_{\mathcal{E}}$-$\mathcal{T}$-left Kan extension of $F|_{\mathcal{C}} : \mathcal{C} \longrightarrow \mathcal{E}$ along the inclusion $\mathcal{C} \longrightarrow \mathcal{C} \star_{\mathcal{O}} \mathcal{O}$.

Proof. Factoring σ_F through the $\mathcal{O}$-monoidal envelope $\mathrm{Ar}^{act}_{\mathcal{T}}(\mathcal{O}^{\otimes})$ of $\mathrm{id} : \mathcal{O}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$, we obtain a pullback square of $\mathcal{O}$-monoidal $\mathcal{T}$-∞-categories and (strong) $\mathcal{O}$-monoidal $\mathcal{T}$-functors

$$\begin{array}{ccc} X & \longrightarrow & \widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C} \star_{\mathcal{O}} \mathcal{O}, \mathcal{E})^{\otimes} \\ \downarrow{\scriptstyle \lambda_F} & & \downarrow{\scriptstyle \lambda} \\ \mathrm{Ar}^{act}_{\mathcal{T}}(\mathcal{O}^{\otimes}) & \xrightarrow{\tau_F} & \widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{E})^{\otimes}. \end{array}$$

We proceed to identify the fibers of λ_F. By definition, for any object $x \in \mathcal{O}^{\otimes}$, $\sigma_F(x)$ is given by the functor $F_{\underline{x}} : \mathcal{C}^{\otimes}_{\underline{x}} \longrightarrow \mathcal{E}^{\otimes}_{\underline{x}}$, and for any fiberwise active edge $\alpha : x \longrightarrow y$, $\tau_F(\alpha)$ is given by the cocartesian pushforward $\alpha_! F_{\underline{x}} : \mathcal{C}^{\otimes}_{\underline{y}} \longrightarrow \mathcal{E}^{\otimes}_{\underline{y}}$. If α decomposes via the $\mathcal{T}$-∞-operad axioms as $(\alpha_i : x_i \longrightarrow y_i)_{1 \leq i \leq n}$ for $y_i \in \mathcal{O}_{V_i}$ (induced by an orbit decomposition $V \simeq V_1 \sqcup ... \sqcup V_n$ if y covers $[V_+ \longrightarrow W]$ in $\underline{\mathbf{F}}_{\mathcal{T},*}$), then $\alpha_! F_{\underline{x}}$ may be explicitly identified as the collection of $\mathcal{T}^{/V_i}$-left Kan extensions $(\alpha_i)_! F_{\underline{x_i}}$ of $(\alpha_i)_{\otimes} \circ F_{\underline{x_i}} : \mathcal{C}^{\otimes}_{\underline{x_i}} \longrightarrow \mathcal{E}_{\underline{y_i}}$ along $(\alpha_i)_{\otimes} : \mathcal{C}^{\otimes}_{\underline{x_i}} \longrightarrow \mathcal{C}_{\underline{y_i}}$. Therefore, the fiber of λ_F over $\{\alpha\}$ is given by

$$\prod_{1 \leq i \leq n} \mathcal{E}_{\underline{y_i}}^{((\alpha_i)_! F_{\underline{x_i}}, \mathcal{T}^{/V_i})/}.$$

Because each $\mathcal{E}_{\underline{y_i}}$ is $\mathcal{T}^{/V_i}$-cocomplete by assumption, these fibers all have initial objects, which are moreover preserved by the cocartesian edges over $\mathcal{T}^{\mathrm{op}}$ (i.e., by restriction). We claim that restricting λ_F to the full $\mathcal{T}$-subcategory X_0 on these initial objects yields a trivial Kan fibration $\lambda'_F : X_0 \longrightarrow \mathrm{Ar}^{act}_{\mathcal{T}}(\mathcal{O}^{\otimes})$. By (2) of

Lemma 4.3.2, λ is $\mathcal{O}^{\otimes}$-cartesian, hence the pulled back map λ_F is $\mathcal{O}^{\otimes}$-cartesian. Therefore, it suffices to check that the cocartesian edges in X over $\mathcal{O}^{\otimes}$ preserve initial objects. This is obvious for cocartesian edges over inert edges in $\mathcal{O}^{\otimes}$, so it suffices to consider the case of a fiberwise active edge $\beta : y \longrightarrow z$ in $\mathcal{O}^{\otimes}_W$ with $z \in \mathcal{O}_W$. Then for our fiberwise active edge $\alpha : x \longrightarrow y \in \mathcal{O}^{\otimes}_W$ above, $\beta_!(\alpha) = \beta \circ \alpha : x \longrightarrow z$ computes the cocartesian pushforward in $\mathrm{Ar}^{act}_{\mathcal{T}}(\mathcal{O}^{\otimes})$. As we have seen, an initial object in X covering α corresponds to a collection of $\mathcal{T}^{/V_i}$-colimits of $(\alpha_i)_! F_{\underline{x_i}}$

$$\begin{array}{ccc} \mathcal{C}_{\underline{y_i}} & \xrightarrow{(\alpha_i)_! F_{\underline{x_i}}} & \mathcal{E}_{\underline{y_i}} \\ \downarrow & & \downarrow \\ (\mathcal{T}^{/V_i})^{\mathrm{op}} & \xrightarrow{=} & (\mathcal{T}^{/V_i})^{\mathrm{op}} \end{array}$$

By our assumption that $\mathcal{E}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ is distributive, applying $\prod_\beta$ and postcomposing with $\otimes_\beta : \mathcal{E}^{\otimes}_{\underline{y}} \longrightarrow \mathcal{E}_{\underline{z}}$ yields a $\mathcal{T}^{/W}$-colimit diagram

$$\begin{array}{ccc} \mathcal{C}^{\otimes}_{\underline{y}} & \longrightarrow & \mathcal{E}_{\underline{z}} \\ \downarrow & & \downarrow \\ (\mathcal{T}^{/W})^{\mathrm{op}} & \xrightarrow{=} & (\mathcal{T}^{/W})^{\mathrm{op}} \end{array}$$

Factoring $\mathcal{C}^{\otimes}_{\underline{y}} \longrightarrow (\mathcal{T}^{/W})^{\mathrm{op}}$ through $\mathcal{C}_{\underline{z}}$ and using the transitivity of $\mathcal{T}^{/W}$-left Kan extensions, this further implies that the diagram

$$\begin{array}{ccc} \mathcal{C}_{\underline{z}} & \xrightarrow{(\beta\circ\alpha)_! F_{\underline{x}}} & \mathcal{E}_{\underline{z}} \\ \downarrow & & \downarrow \\ (\mathcal{T}^{/W})^{\mathrm{op}} & \xrightarrow{=} & (\mathcal{T}^{/W})^{\mathrm{op}} \end{array}$$

is a $\mathcal{T}^{/W}$-colimit diagram, where inspecting the definitions reveals that the top horizontal arrow may be identified with $(\beta \circ \alpha)_! F_{\underline{x}}$. This is an initial object covering $\beta \circ \alpha$, as desired.

Choosing a section of λ'_F and postcomposing by the map $X_0 \longrightarrow \widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C} \star_{\mathcal{O}} \mathcal{O}, \mathcal{E})^{\otimes}$, we obtain the desired extension $\sigma_{\overline{F}}$. Finally, the assertion about $A|_{\mathcal{O}}$ is clear from the construction if we consider only those objects x, $\alpha = \mathrm{id}_x$, and edges β entirely in $\mathcal{O}$. ☐

We can then promote Proposition 4.3.3 to a global existence result.

4.3.4. **Theorem.** *We have $\mathcal{O}^{\otimes}$-adjunctions*

$$\widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C},\mathcal{E})^{\otimes} \underset{\mathrm{ev}_{\mathcal{C}}}{\rightleftarrows} \widetilde{\mathrm{Fun}}_{\mathcal{O},\mathcal{T}}(\mathcal{C} \star_{\mathcal{O}} \mathcal{O},\mathcal{E})^{\otimes} \underset{\delta}{\overset{\mathrm{ev}_{\mathcal{O}}}{\rightleftarrows}} \mathcal{E}^{\otimes}.$$

Consequently, on passing to ∞-categories of $\mathcal{O}$-algebras, we obtain the adjunction

$$p_! \colon \mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{C},\mathcal{E}) \rightleftarrows \mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{E}) : p^*$$

where $p_!$ is computed as in Proposition 4.3.3 and p^* is restriction along p.

Proof. The only subtlety involves the first $\mathcal{O}^{\otimes}$-adjunction. We may invoke [Lur17, 7.3.2.12] because the second condition there is ensured by distributivity in $\mathcal{E}^{\otimes}$, using the same argument as in the proof of Proposition 4.3.3. We can then extract the adjunction involving ∞-categories of $\mathcal{O}$-algebra maps by pulling back along the structure map $\mathrm{ev}_1 : \mathrm{Ar}^{act}_{\mathcal{T}}(\mathcal{O}^{\otimes}) \longrightarrow \mathcal{O}^{\otimes}$ of the $\mathcal{O}$-monoidal envelope and taking cocartesian sections. ☐

Now suppose that $p : \mathcal{C}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ is only a fibration of $\mathcal{T}$-∞-operads and consider the factorization of p through its $\mathcal{O}$-monoidal envelope $\mathrm{Env}_{\mathcal{O},\mathcal{T}}(\mathcal{C})^{\otimes}$. In view of Proposition 2.8.7 and Theorem 4.3.4, we have the composite adjunction

$$p_! : \mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{C},\mathcal{E}) \rightleftarrows \mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathrm{Env}_{\mathcal{O},\mathcal{T}}(\mathcal{C}),\mathcal{E}) \rightleftarrows \mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{E}) : p^*.$$

4.3.5. **Definition.** Given a $\mathcal{O}$-algebra map $F : \mathcal{C}^{\otimes} \longrightarrow \mathcal{E}^{\otimes}$, we define the $\mathcal{T}$-*operadic left Kan extension* of F to be $p_! F$.

4.3.6. **Remark.** Given a fibration of $\mathcal{T}$-∞-operads $\mathcal{O}^{\otimes} \longrightarrow \mathcal{P}^{\otimes}$ and $\mathcal{E}^{\otimes} \longrightarrow \mathcal{P}^{\otimes}$ a distributive $\mathcal{P}$-monoidal $\mathcal{T}$-∞-category, we will also speak of the $\mathcal{T}$-operadic left Kan extension of a $\mathcal{P}$-algebra map $F : \mathcal{C}^{\otimes} \longrightarrow \mathcal{E}^{\otimes}$ along p in the obvious way (note that distributivity is stable under pullback). In other words, we also have an adjunction

$$p_! \colon \mathbf{Alg}_{\mathcal{P},\mathcal{T}}(\mathcal{C}, \mathcal{E}) \rightleftarrows \mathbf{Alg}_{\mathcal{P},\mathcal{T}}(\mathcal{O}, \mathcal{E}) : p^*.$$

Note that the underlying $\mathcal{T}$-functor $p_!(F)|_{\mathcal{O}} : \mathcal{O} \longrightarrow \mathcal{E}$ is computed by first extending F to

$$i_! F : \mathrm{Env}_{\mathcal{O},\mathcal{T}}(\mathcal{C})^{\otimes} \longrightarrow \mathcal{E}^{\otimes}$$

and then taking the $\mathcal{T}$-left Kan extension of $i_! F|_{\mathrm{Env}_{\mathcal{O},\mathcal{T}}(\mathcal{C})}$ along the structure map to $\mathcal{O}$.

4.3.7. **Example.** Suppose that $\mathcal{C}^{\otimes} = \mathrm{Triv}^{\otimes} = (\underline{\mathbf{F}}_{\mathcal{T},*})_{ne}$ and $\mathcal{O}^{\otimes} = \underline{\mathbf{F}}_{\mathcal{T},*}$. Then the $\mathcal{T}$-symmetric monoidal envelope of $\mathrm{Triv}^{\otimes}$ is $(\mathrm{Triv}^{\otimes})_{act} = (\underline{\mathbf{F}}_{\mathcal{T},*})_{cocart}$, the maximal sub-left fibration of $\underline{\mathbf{F}}_{\mathcal{T},*} \longrightarrow \mathcal{T}^{\mathrm{op}}$ obtained by taking the wide subcategory spanned by the cocartesian edges.

In the case that $\mathcal{T} = \mathbf{O}_G$ is the orbit category of a finite group, we can identify this with something familiar. Namely, let Σ_n be the symmetric group on n letters, and let $\mathbf{O}_{G\times\Sigma_n,\Gamma_n}$ be the full subcategory of the orbit category of $G \times \Sigma_n$ on the Σ_n-free transitive $G \times \Sigma_n$-sets. (Recall that every object in this subcategory is isomorphic to an orbit $G \times \Sigma_n/\Gamma_\phi$, where Γ_ϕ is the graph of a homomorphism $\phi : H \longrightarrow \Sigma_n$ for some subgroup H of G.) Define a functor

$$-/\Sigma_n : \mathbf{O}_{G\times\Sigma_n,\Gamma_n} \longrightarrow \mathbf{O}_G,\ U \rightsquigarrow U/\Sigma_n.$$

This is left adjoint to restriction along the projection $G \times \Sigma_n \longrightarrow G$ and sends $(G \times \Sigma_n)/\Gamma_\phi$ to G/H. Then $(-/\Sigma_n)^{\mathrm{op}}$ is a left fibration and exhibits $\mathbf{O}^{\mathrm{op}}_{G\times\Sigma_n,\Gamma_n}$ as a G-∞-category. In fact, $\mathbf{O}^{\mathrm{op}}_{G\times\Sigma_n,\Gamma_n}$ is a model for the G-space $B_G\Sigma_n$ which classifies G-equivariant principal Σ_n-bundles ([QS21a, Rem. 3.17]).

Now define a G-functor $F : \mathbf{O}^{\mathrm{op}}_{G\times\Sigma_n,\Gamma_n} \longrightarrow (\underline{\mathbf{F}}_G)_{cocart}$ which sends an object U to the morphism of G-sets $(U \times n)/\Sigma_n \longrightarrow U/\Sigma_n$ and a morphism $U \longleftarrow V$ to

$$\begin{array}{ccccc} (U\times n)/\Sigma_n & \longleftarrow & (V\times n)/\Sigma_n & \xrightarrow{=} & (U\times n)/\Sigma_n \\ \downarrow & & \downarrow & & \downarrow \\ U/\Sigma_n & \longleftarrow & V/\Sigma_n & \xrightarrow{=} & V/\Sigma_n \end{array}$$

where we note that the left square is a pullback square of G-sets. (Note that this suffices to define a functor since $\underline{\mathbf{F}}_G$ is equivalent to a 1-category.) It follows from Σ_n-freeness and an elementary argument that F is fully faithful. Moreover, taking the disjoint union over all $n \geq 0$ and postcomposing with $(-)_+$, we obtain an equivalence of G-∞-categories

$$\coprod_{n\geq 0} \mathbf{O}^{\mathrm{op}}_{G\times\Sigma_n,\Gamma_n} \xrightarrow{\sim} (\underline{\mathbf{F}}_G)_{cocart} \xrightarrow{\sim} (\underline{\mathbf{F}}_{G,*})_{cocart}.$$

Therefore, for a G-symmetric monoidal ∞-category $\mathcal{C}^{\otimes}$, the free G-commutative algebra on an object $x : \mathbf{O}^{\mathrm{op}}_G \longrightarrow \mathcal{C}$ is computed by the G-colimit of the induced functor

$$\coprod_{n\geq 0} \mathbf{O}^{\mathrm{op}}_{G\times\Sigma_n,\Gamma_n} \longrightarrow \mathcal{C}.$$

4.3.8. **Warning.** In the proofs of Lemma 4.3.2, Proposition 4.3.3 and Theorem 4.3.4, the results would fail if we replaced $(\mathcal{C} \star_{\mathcal{O}} \mathcal{O})^{\otimes}$ by $(\mathcal{O} \star_{\mathcal{O}} \mathcal{C})^{\otimes}$. This corresponds to there generally being no $\mathcal{T}$-operadic *right* Kan extension.

5. $\mathcal{T}$-∞-categories of $\mathcal{O}$-algebras

Let $\mathcal{O}$ be a $\mathcal{T}$-∞-operad. In this section, we study $\mathcal{T}$-limits and $\mathcal{T}$-colimits in the $\mathcal{T}$-∞-category of $\mathcal{O}$-algebras within an $\mathcal{O}$-monoidal $\mathcal{T}$-∞-category. Our results are straightforward generalizations of Lurie's results in [Lur17, §3.2] and overlap with similar work of Bachmann–Hoyois undertaken in [BH21, §7] (in particular, compare [BH21, Prop. 7.6]). Before reading this section, the reader should first review [Sha21b, Thm. 4.16 and Cor. 4.17] on how to compute $\mathcal{T}$-(co)limits in a $\mathcal{T}$-∞-category of sections.

5.1. **Parametrized (co)limits in general.** In this section, let $\mathcal{C}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ be an $\mathcal{O}$-monoidal $\mathcal{T}$-∞-category, let $\mathcal{P}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ be a fibration of $\mathcal{T}$-∞-operads, and let $\mathcal{K} = \{\mathcal{K}_V : V \in \mathcal{T}\}$ be a collection of classes $\mathcal{K}_V$ of small $\mathcal{T}^{/V}$-∞-categories closed with respect to base-change in $\mathcal{T}$. We are interested in criteria for when the $\mathcal{T}$-∞-category $\underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{P}, \mathcal{C})$ of algebras strongly admits $\mathcal{K}$-indexed $\mathcal{T}$-limits and colimits. To solve this problem, we will first need to understand how to compute $\mathcal{T}$-limits and $\mathcal{T}$-colimits in an indexed product.

5.1.1. **Lemma.** *Let $f : \mathcal{T}_0 \longrightarrow \mathcal{T}_1$ be a categorical fibration of ∞-categories, let $\mathcal{C}$ be a $\mathcal{T}_0$-∞-category, and let $\mathcal{K}$ be a $\mathcal{T}_1$-∞-category. Let*

$$f^* \colon \mathbf{Cat}_{\mathcal{T}_1} \rightleftarrows \mathbf{Cat}_{\mathcal{T}_0} : f_*$$

denote the restriction-coinduction adjunction.

(1) Let $(F \colon \mathcal{C} \rightleftarrows \mathcal{D} : G)$ be a $\mathcal{T}_0$-adjunction. Then $(f_* F \colon f_*\mathcal{C} \rightleftarrows f_*\mathcal{D} : f_* G)$ is a $\mathcal{T}_1$-adjunction.

(2) We have a canonical equivalence

$$\underline{\mathrm{Fun}}_{\mathcal{T}_1}(\mathcal{K}, f_*\mathcal{C}) \simeq f_* \underline{\mathrm{Fun}}_{\mathcal{T}_0}(f^*\mathcal{K}, \mathcal{C})$$

under which $\delta_{\mathcal{K}} \simeq f_*(\delta_{f^*\mathcal{K}})$ as $\mathcal{T}_1$-functors with common domain $f_*\mathcal{C}$, where $\delta_{\mathcal{K}}$, resp. $\delta_{f^*\mathcal{K}}$ is the constant $\mathcal{K}$-diagram $\mathcal{T}_1$-functor, resp. constant $f^*\mathcal{K}$-diagram $\mathcal{T}_0$-functor.

(3) Let $p : \mathcal{K} \longrightarrow f_*\mathcal{C}$ be a $\mathcal{T}_1$-functor and let $q : f^*\mathcal{K} \longrightarrow \mathcal{C}$ be its adjoint $\mathcal{T}_0$-functor. Then p admits a $\mathcal{T}_1$-limit if and only if q admits a $\mathcal{T}_0$-limit, and moreover an extension $\overline{p} : \mathcal{K}^{\trianglelefteq} \longrightarrow f_*\mathcal{C}$ is a $\mathcal{T}_1$-limit diagram if and only if the adjoint extension $\overline{q} : (f^*\mathcal{K})^{\trianglelefteq} \simeq f^*(\mathcal{K}^{\trianglelefteq}) \longrightarrow \mathcal{C}$ is a $\mathcal{T}_0$-limit diagram. The analogous statements also hold for parametrized colimits.

Proof. (1): It suffices to show that for all $t \in \mathcal{T}_1$, $(f_*F)_t \dashv (f_*G)_t$ is an adjunction. In fact, since $(f_*\mathcal{C})_t \simeq \mathrm{Fun}_{\mathcal{T}_1}((\mathcal{T}_1^{t/})^{\mathrm{op}}, f_*\mathcal{C})$, we can more generally verify that $\mathrm{Fun}_{\mathcal{T}_1}(\mathcal{K}, f_*F) \dashv \mathrm{Fun}_{\mathcal{T}_1}(\mathcal{K}, f_*G)$ is an adjunction for every $\mathcal{T}_1$-∞-category $\mathcal{K}$. But this holds since

$$\mathrm{Fun}_{\mathcal{T}_0}(f^*\mathcal{K}, F) \colon \mathrm{Fun}_{\mathcal{T}_0}(f^*\mathcal{K}, \mathcal{C}) \rightleftarrows \mathrm{Fun}_{\mathcal{T}_0}(f^*\mathcal{K}, \mathcal{D}) : \mathrm{Fun}_{\mathcal{T}_0}(f^*\mathcal{K}, G)$$

is an adjunction by [Sha21a, Prop. 8.2].
(2): We check the claimed equivalence at the level of representable functors:

$$\begin{aligned}\mathrm{Fun}_{\mathcal{T}_1}(\mathcal{L}, \underline{\mathrm{Fun}}_{\mathcal{T}_1}(\mathcal{K}, f_*\mathcal{C})) &\simeq \mathrm{Fun}_{\mathcal{T}_1}(\mathcal{L} \times_{\mathcal{T}_1^{\mathrm{op}}} \mathcal{K}, f_*\mathcal{C}) \simeq \mathrm{Fun}_{\mathcal{T}_0}(f^*\mathcal{L} \times_{\mathcal{T}_0^{\mathrm{op}}} f^*\mathcal{K}, \mathcal{C}) \\ &\simeq \mathrm{Fun}_{\mathcal{T}_0}(f^*\mathcal{L}, \underline{\mathrm{Fun}}_{\mathcal{T}_0}(f^*\mathcal{K}, \mathcal{C})) \simeq \mathrm{Fun}_{\mathcal{T}_0}(\mathcal{L}, f_*\underline{\mathrm{Fun}}_{\mathcal{T}_0}(f^*\mathcal{K}, \mathcal{C}))\end{aligned}$$

The assertion about constant functors is shown in a similar manner.
(3): This follows from combining (1) and (2). ☐

5.1.2. **Corollary.** *Let $\mathcal{C}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ be a fibration of $\mathcal{T}$-∞-operads, let $f : U \simeq \coprod_{1 \leq i \leq n} U_i \longrightarrow V$ be a morphism in $\mathbf{F}_{\mathcal{T}}$ with U_i and V orbits, let $x \in \mathcal{O}^{\otimes}_{f_+}$, and let $e_i : x \longrightarrow x_i$ be inert edges in $\mathcal{O}^{\otimes}$ lifting the characteristic morphisms $\chi_{[U_i \subset U]}$ in $\underline{\mathbf{F}}_{\mathcal{T},*}$. Suppose $\mathcal{C}_{\underline{x_i}}$ admits all $\mathcal{K}_{U_i}$-indexed $\mathcal{T}^{U_i/}$-(co)limits for each $1 \leq i \leq n$. Then $\mathcal{C}^{\otimes}_{\underline{x}}$ admits all $\mathcal{K}_V$-indexed $\mathcal{T}^{V/}$-(co)limits.*

Proof. Combine Lemma 5.1.1(3) and the Segal equivalence $\mathcal{C}^{\otimes}_{\underline{x}} \simeq \prod_{1 \leq i \leq n} \prod_{f_i} \mathcal{C}_{\underline{x_i}}$ of Theorem 2.3.3. ☐

We may now prove our main result on parametrized limits.

5.1.3. **Theorem.** *Let $\mathcal{C}$ be an $\mathcal{O}$-monoidal $\mathcal{T}$-∞-category and let $\mathcal{P}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ be a fibration of $\mathcal{T}$-∞-operads. Let $\mathcal{K} = \{\mathcal{K}_V : V \in \mathcal{T}\}$ be a collection of classes $\mathcal{K}_V$ of small $\mathcal{T}^{/V}$-∞-categories closed with respect to base-change in $\mathcal{T}$ (e.g., we could take $\mathcal{K}_V$ to be all small $\mathcal{T}^{/V}$-∞-categories for each $V \in \mathcal{T}$). Suppose for all $x \in \mathcal{O}_V$ that $\mathcal{C}_{\underline{x}}$ admits all $\mathcal{K}_V$-indexed $\mathcal{T}^{/V}$-limits. Then:*

(1) Both $\underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{P}, \mathcal{C})$ and $\underline{\mathrm{Fun}}_{/\mathcal{O}^{\otimes},\mathcal{T}}(\mathcal{P}^{\otimes}, \mathcal{C}^{\otimes})$ strongly admit all $\mathcal{K}$-indexed $\mathcal{T}$-limits, and the inclusion

$$\underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{P}, \mathcal{C}) \subset \underline{\mathrm{Fun}}_{/\mathcal{O}^{\otimes},\mathcal{T}}(\mathcal{P}^{\otimes}, \mathcal{C}^{\otimes})$$

strongly preserves all $\mathcal{K}$-indexed $\mathcal{T}$-limits.

(2) $\underline{\mathrm{Fun}}_{/\mathcal{O},\mathcal{T}}(\mathcal{P}, \mathcal{C})$ strongly admits all $\mathcal{K}$-indexed $\mathcal{T}$-limits, and the forgetful $\mathcal{T}$-functor

$$\mathrm{U} : \underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{P}, \mathcal{C}) \longrightarrow \underline{\mathrm{Fun}}_{/\mathcal{O},\mathcal{T}}(\mathcal{P}, \mathcal{C})$$

strongly creates all $\mathcal{K}$-indexed $\mathcal{T}$-limits.

Proof. By [Sha21b, Cor. 4.17] and Corollary 5.1.2, $\underline{\mathrm{Fun}}_{/\mathcal{O}^\otimes,\mathcal{T}}(\mathcal{P}^\otimes,\mathcal{C}^\otimes)$ strongly admits all $\mathcal{K}$-indexed $\mathcal{T}$-limits. Moreover, by the explicit formula for parametrized limits in $\underline{\mathrm{Fun}}_{/\mathcal{O}^\otimes,\mathcal{T}}(\mathcal{P}^\otimes,\mathcal{C}^\otimes)$ given in [Sha21b, 4.16(3)], we see the remaining claims follow from the observation that for every fiberwise inert edge $e : x \longrightarrow x'$ in $\mathcal{O}^\otimes_V$, the associated pushforward functor $e_! : \mathcal{C}^\otimes_{\underline{x}} \longrightarrow \mathcal{C}^\otimes_{\underline{x'}}$ is identified with projection to a subset of factors in a fiber product under the Segal equivalence of Theorem 2.3.3, so in particular preserves all $\mathcal{K}_V$-indexed $\mathcal{T}^{/V}$-limits. This proves (1). (2) then follows by invoking [Sha21b, 4.16(3)] once more. ☐

Next, we handle the case of parametrized colimits, for which we will need an additional distributivity assumption on $\mathcal{C}^\otimes \longrightarrow \mathcal{O}^\otimes$. Let $\mathcal{K}_V$ be the class $\mathcal{K}^{\mathrm{sift}}_V$ of $\mathcal{T}^{/V}$-sifted $\mathcal{T}^{/V}$-colimits and write $\mathcal{K}^{\mathrm{sift}} = \mathcal{K}$.

5.1.4. **Theorem.** *Suppose $\mathcal{C}$ is a distributive $\mathcal{O}$-monoidal $\mathcal{T}$-∞-category (Definition 3.2.4), and let $\mathcal{P}^\otimes \longrightarrow \mathcal{O}^\otimes$ be a fibration of $\mathcal{T}$-∞-operads. Then:*

1. *Both $\underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{P},\mathcal{C})$ and $\underline{\mathrm{Fun}}_{/\mathcal{O}^\otimes,\mathcal{T}}(\mathcal{P}^\otimes,\mathcal{C}^\otimes)$ strongly admit all $\mathcal{K}^{\mathrm{sift}}$-indexed $\mathcal{T}$-colimits, and the inclusion*
$$\underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{P},\mathcal{C}) \subset \underline{\mathrm{Fun}}_{/\mathcal{O}^\otimes,\mathcal{T}}(\mathcal{P}^\otimes,\mathcal{C}^\otimes)$$
strongly preserves all $\mathcal{K}^{\mathrm{sift}}$-indexed $\mathcal{T}$-colimits.
2. *$\underline{\mathrm{Fun}}_{/\mathcal{O},\mathcal{T}}(\mathcal{P},\mathcal{C})$ is $\mathcal{T}$-cocomplete and the forgetful $\mathcal{T}$-functor*
$$\mathrm{U} : \underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{P},\mathcal{C}) \longrightarrow \underline{\mathrm{Fun}}_{/\mathcal{O},\mathcal{T}}(\mathcal{P},\mathcal{C})$$
strongly creates all $\mathcal{K}^{\mathrm{sift}}$-indexed $\mathcal{T}$-colimits.
3. *$\underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{P},\mathcal{C})$ is $\mathcal{T}$-cocomplete.*
4. *Suppose in addition that $\mathcal{C}$ is fiberwise presentable. Then $\underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{P},\mathcal{C})$ is fiberwise presentable.*

Proof. (1) and (2): To show the claim for $\underline{\mathrm{Fun}}_{/\mathcal{O}^\otimes,\mathcal{T}}(\mathcal{P}^\otimes,\mathcal{C}^\otimes)$, we verify the criterion of [Sha21b, Thm. 4.16(4)]. Since a fiberwise morphism $\alpha : x \longrightarrow y$ in $\mathcal{O}^\otimes_V$ factors as the composite of a fiberwise inert edge and a fiberwise active edge, and the pushforward functor associated to a fiberwise inert edge is a projection, we may suppose α is fiberwise active. Moreover, using again the Segal equivalence of Theorem 2.3.3, we may suppose that α covers a fiberwise active edge $f_+ : [U_+ \to V] \longrightarrow [V_+ \to V]$ in $\underline{\mathbf{F}}_{\mathcal{T},*}$ defined by a map $f : U \longrightarrow V$ of finite $\mathcal{T}$-sets. Then using the distributive hypothesis on $\mathcal{C}^\otimes$ together with [Sha21b, Prop. 8.19], we have that the pushforward $\mathcal{T}^{/V}$-functor $\alpha_! = \otimes_\alpha : \mathcal{C}^\otimes_{\underline{x}} \longrightarrow \mathcal{C}_{\underline{y}}$ preserves all $\mathcal{K}^{\mathrm{sift}}_V$-indexed colimits, so $\underline{\mathrm{Fun}}_{/\mathcal{O}^\otimes,\mathcal{T}}(\mathcal{P}^\otimes,\mathcal{C}^\otimes)$ strongly admits all $\mathcal{K}^{\mathrm{sift}}$-indexed $\mathcal{T}$-colimits. Similarly, we see that $\underline{\mathrm{Fun}}_{/\mathcal{O},\mathcal{T}}(\mathcal{P},\mathcal{C})$ is $\mathcal{T}$-cocomplete. The remaining claims then follow as in the proof of Theorem 5.1.3, now using [Sha21b, Thm. 4.16(4)].

(3): By part (1) and [Sha21a, Cor. 12.15] (or [Sha21b, Thm. 8.6]), it suffices to check that $\underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{P},\mathcal{C})$ admits finite $\mathcal{T}$-coproducts. For this, we employ the same strategy as in the proof of [Lur17, Cor. 3.2.3.3]. Pulling back $\mathcal{C}^\otimes \longrightarrow \mathcal{O}^\otimes$ via $\mathcal{P}^\otimes \longrightarrow \mathcal{O}^\otimes$, we may suppose $\mathcal{P}^\otimes = \mathcal{O}^\otimes$ without loss of generality. Now let $\mathcal{O}^\otimes_{ne} = \mathcal{O}^\otimes \times_{\underline{\mathbf{F}}_{\mathcal{T},*}} \mathrm{Triv}^\otimes_{\mathcal{T}}$ and note that by Lemma 2.4.4 and Corollary 2.4.5, we have that $\underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{O}_{ne},\mathcal{C}) \simeq \underline{\mathrm{Fun}}_{/\mathcal{O},\mathcal{T}}(\mathcal{O},\mathcal{C})$. By Theorem 4.3.4, we thus obtain the free-forgetful $\mathcal{T}$-adjunction
$$\mathrm{F} \colon \underline{\mathrm{Fun}}_{/\mathcal{O},\mathcal{T}}(\mathcal{O},\mathcal{C}) \rightleftarrows \underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{C}) : \mathrm{U}$$
as an instance of $\mathcal{T}$-operadic left Kan extension along $\mathcal{O}^\otimes_{ne} \longrightarrow \mathcal{O}^\otimes$. This implies that each fiber $\underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{C})_V$ admits finite coproducts of free objects, and for each morphism $\alpha : V \longrightarrow W$ in $\mathcal{T}$, the putative left adjoint $\alpha_!$ to the restriction functor $\alpha^* : \underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{C})_W \longrightarrow \underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{C})_V$ is at least defined on the full subcategory of free objects, using the pointwise criterion for the existence of an adjoint. By part (2) and the observation that U is fiberwise conservative, the assumptions of [Lur17, Prop. 4.7.3.14] are satisfied for each of the adjunctions $\mathrm{F}_V \dashv \mathrm{U}_V$, so for each object $A \in \underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{C})_V$, there exists a simplicial object $A_\bullet$ such that each A_n is free and $A \simeq |A_\bullet|$. It follows that the requisite finite coproducts and left adjoints exist for $\underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{C})$. Finally, verification of the base-change condition also reduces to free objects in the same way.

(4): Upon replacing $\mathcal{T}$ by $\mathcal{T}^{/V}$ this amounts to showing that $\mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{P},\mathcal{C})$ is presentable. Given (3), it remains to show that $\mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{P},\mathcal{C})$ is accessible. But since all the pushforward functors $\alpha_! : \mathcal{C}^\otimes_x \longrightarrow \mathcal{C}^\otimes_{x'}$ indexed by morphisms $\alpha : x \longrightarrow x' \in \mathcal{O}^\otimes$ preserve sifted colimits (which reduces to the aforementioned assertion for fiberwise active α given the inert-fiberwise active factorization on $\mathcal{O}^\otimes$), this follows from [Lur09, Prop. 5.4.7.11] in exactly the same way as in the proof of [Lur17, Cor. 3.2.3.5]. ☐

5.1.5. **Corollary.** *Suppose $\mathcal{C}$ is a distributive $\mathcal{O}$-monoidal $\mathcal{T}$-∞-category. Then the free-forgetful $\mathcal{T}$-adjunction*

$$\mathrm{F}\colon \underline{\mathrm{Fun}}_{/\mathcal{O},\mathcal{T}}(\mathcal{O},\mathcal{C}) \rightleftarrows \underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{C}) : \mathrm{U}$$

of Theorem 4.3.4 applied to $\mathcal{O}^{\otimes}_{ne} \subset \mathcal{O}^{\otimes}$ is fiberwise monadic.

Proof. We verify the hypotheses of the Barr–Beck–Lurie Theorem [Lur17, Thm. 4.7.3.5]. After Theorem 5.1.4(2), it only remains to note that U is fiberwise conservative, which is immediate from the definitions. □

5.2. **Units and initial objects.** In this subsection, we identify $\mathcal{T}$-initial objects in $\underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{C})$ in the case where $\mathcal{O}^{\otimes}$ is a *unital* $\mathcal{T}$-∞-operad and $\mathcal{C}^{\otimes}$ is any $\mathcal{O}$-monoidal $\mathcal{T}$-∞-category.

5.2.1. **Definition.** Let $\mathcal{O}^{\otimes}$ be a $\mathcal{T}$-∞-operad. We say that $\mathcal{O}^{\otimes}$ is *unital* if for all orbits $V \in \mathcal{T}$ and objects $x \in \mathcal{O}_V$, the space of multimorphisms $\mathrm{Mul}_{\mathcal{O}}(\emptyset, x)$ is contractible.

For example, $\underline{\mathbf{F}}_{\mathcal{T},*}$ is unital and $\mathrm{Triv}^{\otimes}_{\mathcal{T}}$ is not unital. We next introduce the minimal $\mathcal{T}$-suboperad of $\underline{\mathbf{F}}_{\mathcal{T},*}$ which remains unital.

5.2.2. **Definition.** Let $\mathbf{E}^{\otimes}_{0,\mathcal{T}} \subset \underline{\mathbf{F}}_{\mathcal{T},*}$ be the $\mathcal{T}$-suboperad given by the wide subcategory on those morphisms

$$\begin{array}{ccccc} U & \longleftarrow & Z & \xrightarrow{m} & X \\ \downarrow & & \downarrow & & \downarrow \\ V & \longleftarrow & Y & \xrightarrow{=} & Y \end{array}$$

for which m is a summand inclusion.

Given any $\mathcal{T}$-∞-operad $\mathcal{O}^{\otimes}$, we will then write $\mathcal{O}^{\otimes}_0$ for the pullback $\mathbf{E}^{\otimes}_{0,\mathcal{T}} \times_{\underline{\mathbf{F}}_{\mathcal{T},*}} \mathcal{O}^{\otimes}$ in this subsection. Note that the inclusion $\mathbf{E}^{\otimes}_{0,\mathcal{T}} \subset \underline{\mathbf{F}}_{\mathcal{T},*}$ is stable under equivalences and is thus a fibration of $\mathcal{T}$-∞-operads, and the same is true for the pullback $\mathcal{O}^{\otimes}_0 \subset \mathcal{O}^{\otimes}$.

5.2.3. **Remark.** Let $\mathcal{O}^{\otimes}$ be a $\mathcal{T}$-∞-operad and for each orbit $V \in \mathcal{T}$, let $*_V$ be a choice of object in the fiber $\mathcal{O}^{\otimes}_{[\emptyset_+ \to V]} \simeq *$, which is unique up to contractible choice. We note that $*_V$ is a final object in $\mathcal{O}^{\otimes}_V$. Indeed, if $\mathcal{O}^{\otimes} = \underline{\mathbf{F}}_{\mathcal{T},*}$, then $[\emptyset_+ \to V]$ is a zero object in $(\underline{\mathbf{F}}_{\mathcal{T},*})_V \simeq \mathbf{F}_{\mathcal{T}/V,*}$, and the general case follows by the definition of a $\mathcal{T}$-∞-operad. Since for each $\alpha : V \longrightarrow W \in \mathcal{T}$ we have that $\alpha^*(*_W) \simeq *_V$, the $*_V$ assemble to define a $\mathcal{T}$-final object $* : \mathcal{T}^{\mathrm{op}} \longrightarrow \mathcal{O}^{\otimes}$.

Now suppose $\mathcal{O}^{\otimes}$ is unital. Then by the same reasoning, we see that $*_V$ is a zero object in $\mathcal{O}^{\otimes}_V$ and hence $*$ is a $\mathcal{T}$-zero object. In this case, we will also write 0_V for $*_V$ and 0 for $*$.

5.2.4. **Definition.** We define the $\mathcal{T}$-functor $\omega : \Delta^1 \times \mathcal{T}^{\mathrm{op}} \longrightarrow \underline{\mathbf{F}}_{\mathcal{T},*}$ to be the unique homotopy from 0 to $I(-)_+$. For a unital $\mathcal{T}$-∞-operad $\mathcal{O}^{\otimes}$, we then define the $\mathcal{T}$-functor $\omega_{\mathcal{O}}$ lying in the commutative diagram

$$\begin{array}{ccccc} \mathcal{O}^{\trianglelefteq} & \xrightarrow{\omega_{\mathcal{O}}} & \mathcal{O}^{\otimes}_0 & \longrightarrow & \mathcal{O}^{\otimes} \\ \downarrow & & \downarrow & & \downarrow \\ \Delta^1 \times \mathcal{T}^{\mathrm{op}} & \xrightarrow{\omega} & \mathbf{E}^{\otimes}_{0,\mathcal{T}} & \longrightarrow & \underline{\mathbf{F}}_{\mathcal{T},*} \end{array}$$

to be the unique $\mathcal{T}$-functor extending the inclusion $\mathcal{O} \subset \mathcal{O}^{\otimes}_0$ of the underlying ∞-category, whose restriction along the cone inclusion $\mathcal{T}^{\mathrm{op}} \subset \mathcal{O}^{\trianglelefteq}$ is 0.

For an $\mathcal{O}$-monoidal $\mathcal{T}$-∞-category $p : \mathcal{C}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$, we define the $\mathcal{T}$-functor $\widetilde{\omega}_{\mathcal{C}}$ lying in the commutative diagram

$$\begin{array}{ccccc} \mathcal{O}^{\trianglelefteq} & \xrightarrow{\widetilde{\omega}_{\mathcal{C}}} & \mathcal{C}^{\otimes}_0 & \longrightarrow & \mathcal{C}^{\otimes} \\ & \searrow^{\omega_{\mathcal{O}}} & \downarrow & & \downarrow p \\ & & \mathcal{O}^{\otimes}_0 & \longrightarrow & \mathcal{O}^{\otimes} \end{array}$$

to be the unique lift of $\omega_{\mathcal{O}}$ so that $\widetilde{\omega}_{\mathcal{C}}$ sends the edges $(0_V \longrightarrow x) \in \mathcal{O}^{\triangleleft}_V$ to p-cocartesian edges (and hence all edges to p-cocartesian edges).

We then define the *unit* of $(\mathcal{C}^{\otimes}, p)$ to be the $\mathcal{T}$-functor $1 := \widetilde{\omega}_{\mathcal{C}}|_{\mathcal{O}} : \mathcal{O} \longrightarrow \mathcal{C}$.

5.2.5. **Remark.** The $\mathcal{T}$-functors ω, $\omega_{\mathcal{O}}$, and $\widetilde{\omega}_{\mathcal{C}}$ of Definition 5.2.4 may be defined rigorously as follows. For ω, choose a section σ of the trivial fibration $\mathcal{T}^{\mathrm{op}} \times_{0,\mathbf{E}^{\otimes}_{0,\mathcal{T}},\mathrm{ev}_0} \mathrm{Ar}_{\mathcal{T}}(\mathbf{E}^{\otimes}_{0,\mathcal{T}}) \xrightarrow{\mathrm{ev}_1} \mathbf{E}^{\otimes}_{0,\mathcal{T}}$ of Lemma 5.2.6 and define ω to be the adjoint to the composite $\omega^{\perp} = \mathrm{pr} \circ \sigma \circ I_+ : \mathcal{T}^{\mathrm{op}} \longrightarrow \mathrm{Ar}_{\mathcal{T}}(\mathbf{E}^{\otimes}_{0,\mathcal{T}})$.

Then for $\omega_{\mathcal{O}}$, choose a section $\sigma_{\mathcal{O}}$ of the trivial fibration ψ of Lemma 5.2.6 applied to $\mathcal{O}^{\otimes}_0 \longrightarrow \mathbf{E}^{\otimes}_{0,\mathcal{T}}$, let $\rho : \mathcal{O} \longrightarrow \mathcal{T}^{\mathrm{op}}$ and $i : \mathcal{O} \subset \mathcal{O}^{\otimes}_0$ denote the structure map and inclusion, and define the $\mathcal{T}$-functor

$$\omega^{\perp}_{\mathcal{O}} = \sigma \circ (\omega^{\perp}\rho, i) : \mathcal{O} \longrightarrow (\mathcal{T}^{\mathrm{op}} \times_{\mathbf{E}^{\otimes}_{0,\mathcal{T}}} \mathrm{Ar}_{\mathcal{T}}(\mathbf{E}^{\otimes}_{0,\mathcal{T}})) \times_{\mathbf{E}^{\otimes}_{0,\mathcal{T}}} \mathcal{O}^{\otimes}_0 \xrightarrow{\simeq} \mathcal{T}^{\mathrm{op}} \times_{0,\mathcal{O}^{\otimes}_0,\mathrm{ev}_0} \mathrm{Ar}_{\mathcal{T}}(\mathcal{O}^{\otimes}_0).$$

By [Sha21a, Cor. 4.27] and [Sha21a, Prop. 4.30], for any $\mathcal{T}$-∞-category $\mathcal{D}$ and cocartesian section $\phi : \mathcal{T}^{\mathrm{op}} \longrightarrow \mathcal{D}$ we have natural equivalences

$$\mathcal{D}_{(\phi,\mathcal{T})/} \xrightarrow{\simeq} \mathcal{D}^{(\phi,\mathcal{T})/} \xrightarrow{\simeq} \mathcal{T}^{\mathrm{op}} \times_{\phi,\mathcal{D}} \mathrm{Ar}_{\mathcal{T}}(\mathcal{D}),$$

and by [Sha21a, Prop. 4.25] for any $\mathcal{T}$-∞-category $\mathcal{A}$ we have the natural $\mathcal{T}$-join and slice equivalence

$$\underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{A}, \mathcal{D}_{(\phi,\mathcal{T})/}) \xrightarrow{\simeq} \underline{\mathrm{Fun}}_{\mathcal{T}//\mathcal{T}}(\mathcal{A}^{\underline{\triangleleft}}, \mathcal{D}).$$

We may thus adjoin $\omega^{\perp}_{\mathcal{O}}$ to define $\omega_{\mathcal{O}}$ so that it fits into the indicated commutative diagram over ω.

Finally, to define $\widetilde{\omega}_{\mathcal{C}}$, first let $* : \mathcal{T}^{\mathrm{op}} \longrightarrow \mathcal{C}^{\otimes}_0$ be a lift of 0 to the $\mathcal{T}$-final object of Remark 5.2.3, and let $\sigma_{\mathcal{C}} : \mathcal{C}^{\otimes}_0 \times_{\mathcal{O}^{\otimes}_0} \mathrm{Ar}(\mathcal{O}^{\otimes}_0) \xrightarrow{\simeq} \mathrm{Ar}^{cocart}(\mathcal{C}^{\otimes}_0)$ be a choice of section for the trivial fibration. We then have the composite

$$\mathcal{T}^{\mathrm{op}} \times_{0,\mathcal{O}^{\otimes}_0} \mathrm{Ar}(\mathcal{O}^{\otimes}_0) \xrightarrow{*\times\mathrm{id}} \mathcal{C}^{\otimes}_0 \times_{\mathcal{O}^{\otimes}_0} \mathrm{Ar}(\mathcal{O}^{\otimes}_0) \xrightarrow{\sigma_{\mathcal{C}}} \mathrm{Ar}^{cocart}(\mathcal{C}^{\otimes}_0) \subset \mathrm{Ar}(\mathcal{C}^{\otimes}_0),$$

which restricts to

$$f : \mathcal{T}^{\mathrm{op}} \times_{0,\mathcal{O}^{\otimes}_0} \mathrm{Ar}_{\mathcal{T}}(\mathcal{O}^{\otimes}_0) \longrightarrow \mathcal{T}^{\mathrm{op}} \times_{*,\mathcal{C}^{\otimes}_0} \mathrm{Ar}_{\mathcal{T}}(\mathcal{C}^{\otimes}_0).$$

The adjoint of $f \circ \omega^{\perp}_{\mathcal{O}}$ then defines the lift $\widetilde{\omega}_{\mathcal{C}}$ of $\omega_{\mathcal{O}}$.

We also verify the uniqueness assertion for $\widetilde{\omega}_{\mathcal{C}}$ and leave that for $\omega_{\mathcal{O}}$ as an exercise for the reader. By Lemma 5.2.7, the functor given by restriction along the $\mathcal{T}$-cone point

$$\mathrm{Fun}^{cocart}_{/\mathcal{O}^{\otimes}_0}(\mathcal{O}^{\underline{\triangleleft}}, \mathcal{C}^{\otimes}_0) \longrightarrow \mathrm{Fun}_{\mathcal{T}}(\mathcal{T}^{\mathrm{op}}, \mathcal{C}^{\otimes} \times_{\mathcal{O}^{\otimes},0} \mathcal{T}^{\mathrm{op}})$$

is an equivalence, and since $\mathcal{C}^{\otimes} \times_{\mathcal{O}^{\otimes},0} \mathcal{T}^{\mathrm{op}} \simeq \mathcal{T}^{\mathrm{op}}$, we see that the righthand side is contractible, which shows the claim (and gives another construction of $\widetilde{\omega}_{\mathcal{C}}$).

5.2.6. **Lemma.** *Suppose $q : \mathcal{D} \longrightarrow \mathcal{B}$ is a $\mathcal{T}$-fibration and $0 : \mathcal{T}^{\mathrm{op}} \longrightarrow \mathcal{D}$ is a $\mathcal{T}$-functor such that 0 and $q \circ 0$ are $\mathcal{T}$-initial objects. Then the $\mathcal{T}$-functor*

$$\psi : (\mathcal{T}^{\mathrm{op}} \times_{0,\mathcal{D},\mathrm{ev}_0} \mathrm{Ar}_{\mathcal{T}}(\mathcal{D})) \longrightarrow (\mathcal{T}^{\mathrm{op}} \times_{0,\mathcal{B},\mathrm{ev}_0} \mathrm{Ar}_{\mathcal{T}}(\mathcal{B})) \times_{\mathrm{ev}_1,\mathcal{B},q} \mathcal{D}$$

is a trivial fibration.

Proof. Since q is a categorical fibration, it follows that ψ is as well. It thus suffices to prove that ψ is a categorical equivalence, for which we may suppose that $\mathcal{B} = \mathcal{T}^{\mathrm{op}}$ by the two-out-of-three property of equivalences. The claim then follows by our hypothesis that 0_V is initial for all $V \in \mathcal{T}$. ☐

5.2.7. **Lemma.** *Let $q : \mathcal{D} \longrightarrow \mathcal{B}$ be a $\mathcal{T}$-cocartesian fibration and let $i : \mathcal{T}^{\mathrm{op}} \longrightarrow \mathcal{B}$ be a $\mathcal{T}$-initial object. Then the $\mathcal{T}$-functor*

$$i^* : \underline{\mathrm{Fun}}^{cocart}_{/\mathcal{B},\mathcal{T}}(\mathcal{B}, \mathcal{D}) \xrightarrow{\simeq} \mathcal{T}^{\mathrm{op}} \times_{\mathcal{B}} \mathcal{D}$$

is an equivalence.

Proof. It suffices to check the assertion fiberwise. Replacing $\mathcal{T}$ by $\mathcal{T}^{/V}$, we may further suppose that $\mathcal{T}$ has a final object $*$, and we reduce to showing that $i^* : \mathrm{Fun}^{cocart}_{/\mathcal{B}}(\mathcal{B}, \mathcal{D}) \longrightarrow \mathrm{Fun}^{cocart}_{/\mathcal{T}^{\mathrm{op}}}(\mathcal{T}^{\mathrm{op}}, \mathcal{T}^{\mathrm{op}} \times_{\mathcal{B}} \mathcal{D})$ is an equivalence of ∞-categories, or equivalently, that $(\mathcal{T}^{\mathrm{op}})^{\sharp} \longrightarrow \mathcal{B}^{\sharp}$ is a cocartesian equivalence in $\mathbf{sSet}^+_{/\mathcal{B}}$. But the inclusion of the initial object $* \in \mathcal{T}^{\mathrm{op}}$ is a cocartesian equivalence to both $(\mathcal{T}^{\mathrm{op}})^{\sharp}$ and $\mathcal{B}^{\sharp}$, so by the two-out-of-three property of the cocartesian equivalences we are done. ☐

We may canonically endow the unit of an $\mathcal{O}$-monoidal $\mathcal{T}$-∞-category with the structure of an $\mathcal{O}$-algebra in the following way.

5.2.8. **Proposition.** *Let $\mathcal{O}^{\otimes}$ be a unital $\mathcal{T}$-∞-operad and let $p : \mathcal{C}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ be an $\mathcal{O}$-monoidal $\mathcal{T}$-∞-category. Then there is a unique cocartesian section $1^{\otimes}$ of p such that $1^{\otimes}$ extends the unit $1 : \mathcal{O} \longrightarrow \mathcal{C}$.*

Proof. Since $\mathcal{O}^{\otimes}$ has the $\mathcal{T}$-initial object 0 by assumption, the claim follows from Lemma 5.2.7. □

We next identify $\mathcal{O}_0^{\otimes}$-monoidal $\mathcal{T}$-∞-categories and $\mathcal{O}_0$-algebras therein in more familiar terms.

5.2.9. **Proposition.** *Let $\mathcal{O}^{\otimes}$ be a unital $\mathcal{T}$-∞-operad.*

1. *Suppose $(\mathcal{C}^{\otimes}, p)$ is a $\mathcal{O}$-monoidal $\mathcal{T}$-∞-category and let $F^{un}_{\mathcal{C}} : \mathcal{O}_0^{\otimes} \longrightarrow \mathbf{Cat}$ be the functor classifying the cocartesian fibration $p|_{\mathcal{O}_0^{\otimes}}$. Then $F^{un}_{\mathcal{C}}$ is the right Kan extension of its restriction $f^{un}_{\mathcal{C}}$ along $\omega_{\mathcal{O}}$.*
2. *Let $f : \mathcal{O}^{\trianglelefteq} \longrightarrow \mathbf{Cat}$ be a functor whose restriction along the cone inclusion $\mathcal{T}^{\mathrm{op}} \subset \mathcal{O}^{\trianglelefteq}$ is constant at the final object, and let F be the right Kan extension of f along $\omega_{\mathcal{O}}$. The cocartesian fibration $q : \mathcal{D} \longrightarrow \mathcal{O}_0^{\otimes}$ classifed by F is then an $\mathcal{O}_0$-monoidal $\mathcal{T}$-∞-category.*
3. *The assignment $(\mathcal{C}^{\otimes}, p) \mapsto (* \to f_{\mathcal{C}})$ (where $f_{\mathcal{C}}$ denotes the restriction of $f^{un}_{\mathcal{C}}$ to $\mathcal{C}$, regarded as pointed in $\mathrm{Fun}(\mathcal{O}, \mathbf{Cat})$ via the unit $1 : \mathcal{O} \longrightarrow \mathcal{C}$) implements an equivalence of ∞-categories*
$$\mu : \mathbf{Cat}^{\otimes}_{\mathcal{O}_0} \xrightarrow{\simeq} \mathrm{Fun}(\mathcal{O}, \mathbf{Cat})^{*/}$$
and an equivalence of $\mathcal{T}$-∞-categories
$$\underline{\mathbf{Cat}}^{\otimes}_{\mathcal{O}_0} \xrightarrow{\simeq} \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{O}, (\underline{\mathbf{Cat}}_{\mathcal{T}})^{(*,\mathcal{T})/}).$$
4. *For any two $\mathcal{O}$-monoidal $\mathcal{T}$-∞-categories $\mathcal{C}^{\otimes}$ and $\mathcal{D}^{\otimes}$, μ induces an equivalence of ∞-categories*
$$\mathrm{Fun}^{\otimes}_{\mathcal{O}_0,\mathcal{T}}(\mathcal{C}_0, \mathcal{D}_0) \xrightarrow{\simeq} \mathrm{Nat}_*(f_{\mathcal{C}}, f_{\mathcal{D}}).$$

Proof. We first analyze right Kan extension along $\omega_{\mathcal{O}}$ in general. Let $x \in \mathcal{O}^{\otimes}_{[U_+ \to V]}$, let $U \simeq \coprod_{i=1}^n U_i$ be an orbit decomposition, and let $\rho_i : x \longrightarrow x_i$ be cocartesian edges lifting the characteristic morphisms $\chi_{[U_i \subset U]}$. Let $\mathcal{A}, \mathcal{B} \subset \mathcal{O}^{\trianglelefteq} \times_{\mathcal{O}_0^{\otimes}} (\mathcal{O}_0^{\otimes})^{x/}$ be the full subcategories on objects over
$$\begin{pmatrix} U & \longleftarrow & Z & \longrightarrow & X \\ \downarrow & & \downarrow & & \downarrow \\ V & \longleftarrow & Y & \xrightarrow{=} & Y \end{pmatrix} \in (\Delta^1 \times \mathcal{T}^{\mathrm{op}}) \times_{\mathbf{E}^{\otimes}_{0,\mathcal{T}}} (\mathbf{E}^{\otimes}_{0,\mathcal{T}})^{[U_+ \to V]/}$$
such that $Z = \emptyset$ and $Z \neq \emptyset$, respectively, and note that $\mathcal{O}^{\trianglelefteq} \times_{\mathcal{O}_0^{\otimes}} (\mathcal{O}_0^{\otimes})^{x/}$ decomposes as the disjoint union of $\mathcal{A}$ and $\mathcal{B}$. Let $\phi = \phi_A \sqcup \phi_B : \{a\} \sqcup \mathrm{Orbit}(U) \longrightarrow \mathcal{A} \sqcup \mathcal{B}$ be the functor that sends a to $(x \to 0_V)$ and U_i to ρ_i.

We claim that ϕ is right cofinal. By the same argument as in the proof of Lemma 2.4.4, ϕ_B is right cofinal, so it only remains to show $(x \to 0_V)$ is an initial object in $\mathcal{A}$. Since $\mathcal{O}^{\trianglelefteq} \times_{\mathcal{O}_0^{\otimes}} (\mathcal{O}_0^{\otimes})^{x/} \longrightarrow \mathcal{O}^{\trianglelefteq} \longrightarrow \mathcal{T}^{\mathrm{op}}$ is a cocartesian fibration, it suffices to show that for all morphisms $\alpha : W \longrightarrow V \in \mathcal{T}$, $\alpha^*(x \to 0_V) \simeq (x \to 0_W)$ is an initial object in $\mathcal{B}_W$. We first check that for objects $(x \to y) \in \mathcal{B}$ covering $\gamma : [U_+ \to V] \longrightarrow I(W)_+$, the mapping space $\mathrm{Map}_{\mathcal{B}_W}(x \to 0_W, x \to y)$ is contractible. This mapping space fits into the commutative diagram
$$\begin{array}{ccccc} \mathrm{Map}_{\mathcal{B}_W}(x \to 0_W, x \to y) & \longrightarrow & \mathrm{Map}_{(\mathcal{O}_0^{\otimes})^{x/}}(x \to 0_W, x \to y) & \longrightarrow & * \\ \downarrow & & \downarrow & & \downarrow{\scriptstyle (x \to y)} \\ * \simeq \mathrm{Map}_{\mathcal{O}^{\trianglelefteq}_W}(0_W, y) & \longrightarrow & \mathrm{Map}_{\mathcal{O}_0^{\otimes}}(0_W, y) & \xrightarrow{(x \to 0_W)^*} & \mathrm{Map}_{\mathcal{O}_0^{\otimes}}(x, y), \end{array}$$
where the lower horizontal composite selects the inert-fiberwise active factorization of $x \longrightarrow y$ in the connected component $\mathrm{Map}^{\gamma}_{\mathcal{O}_0^{\otimes}}(x, y)$. In fact, since $\mathrm{Mul}_{\mathcal{O}}(\emptyset, y) \simeq *$, this map is an equivalence onto that connected component, and the contractibility of $\mathrm{Map}_{\mathcal{B}_W}(x \to 0_W, x \to y)$ follows. Finally, the argument for $(x \to 0_W)$ itself proceeds the same way.

We conclude that given a functor $f : \mathcal{O}^{\trianglelefteq} \longrightarrow \mathbf{Cat}$, the right Kan extension $(\omega_{\mathcal{O}})_* f$ sends x to $f(0_V) \times \prod_{i=1}^n f(x_i)$. This shows (1) – more precisely, the unit map $F^{un}_{\mathcal{C}} \xrightarrow{\simeq} (\omega_{\mathcal{O}})_*(\omega_{\mathcal{O}})^* F^{un}_{\mathcal{C}}$ is seen to be an equivalence. By Proposition 2.2.6, this also shows (2). Moreover, we see that $(\omega_{\mathcal{O}})^*(\omega_{\mathcal{O}})_* f \xrightarrow{\simeq} f$ if and only if $f|_{\mathcal{T}^{\mathrm{op}}}$ is constant at $* \in \mathbf{Cat}$. We deduce that the adjunction $(\omega_{\mathcal{O}})^* \dashv (\omega_{\mathcal{O}})_*$ restricts to an adjoint equivalence
$$(\omega_{\mathcal{O}})^* : \mathbf{Cat}^{\otimes}_{\mathcal{O}_0} \rightleftarrows \mathrm{Fun}'(\mathcal{O}^{\trianglelefteq}, \mathbf{Cat}) : (\omega_{\mathcal{O}})_*$$
where we take the righthand side to consist of the full subcategory on functors $\mathcal{O}^{\trianglelefteq} \longrightarrow \mathbf{Cat}$ that restrict to $*$ on $\mathcal{T}^{\mathrm{op}}$. Note that since the inclusion of a final object is fully faithful, we have an equivalence
$$\mathrm{Fun}'(\mathcal{O}^{\trianglelefteq}, \mathbf{Cat}) \simeq \Delta^0 \times_{*,\mathrm{Fun}(\mathcal{T}^{\mathrm{op}}, \mathbf{Cat})} \mathrm{Fun}(\mathcal{O}^{\trianglelefteq}, \mathbf{Cat}),$$

and under the equivalence $\mathrm{Fun}_{\mathcal{T}}(\mathcal{O}^{\trianglelefteq}, \mathbf{Cat}) \simeq \mathrm{Fun}_{\mathcal{T}}(\mathcal{O}^{\trianglelefteq}, \underline{\mathbf{Cat}}_{\mathcal{T}})$ of [Sha21a, Prop. 3.9], this yields an equivalence

$$\mathrm{Fun}'(\mathcal{O}^{\trianglelefteq}, \mathbf{Cat}) \simeq \mathrm{Fun}_{\mathcal{T}//\mathcal{T}}(\mathcal{O}^{\trianglelefteq}, \underline{\mathbf{Cat}}_{\mathcal{T}})$$

to the ∞-category of $\mathcal{T}$-functors $\mathcal{O}^{\trianglelefteq} \longrightarrow \underline{\mathbf{Cat}}_{\mathcal{T}}$ that restrict on $\mathcal{T}^{\mathrm{op}}$ to the $\mathcal{T}$-final object of $\underline{\mathbf{Cat}}_{\mathcal{T}}$. By the $\mathcal{T}$-join and slice adjunction of [Sha21a, Prop. 4.25] (together with [Sha21a, Cor. 4.27]), we have an equivalence

$$\underline{\mathrm{Fun}}_{\mathcal{T}//\mathcal{T}}(\mathcal{O}^{\trianglelefteq}, \underline{\mathbf{Cat}}_{\mathcal{T}}) \simeq \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{O}, (\underline{\mathbf{Cat}}_{\mathcal{T}})^{(*,\mathcal{T})/}),$$

which we claim yields an equivalence $\mathrm{Fun}_{\mathcal{T}//\mathcal{T}}(\mathcal{O}^{\trianglelefteq}, \underline{\mathbf{Cat}}_{\mathcal{T}}) \simeq \mathrm{Fun}(\mathcal{O}, \mathbf{Cat})^{*/}$ upon passage to cocartesian sections – for this, just examine the pullback square of ∞-categories

$$\begin{array}{ccc} \mathrm{Fun}_{\mathcal{T}}(\mathcal{O}, (\underline{\mathbf{Cat}}_{\mathcal{T}})^{(*,\mathcal{T})/}) & \longrightarrow & \mathrm{Fun}_{\mathcal{T}}(\mathcal{O}, \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{T}^{\mathrm{op}} \times \Delta^1, \underline{\mathbf{Cat}}_{\mathcal{T}})) \simeq \mathrm{Fun}(\Delta^1, \mathrm{Fun}(\mathcal{O}, \mathbf{Cat})) \\ \downarrow & & \downarrow \\ \mathrm{Fun}_{\mathcal{T}}(\mathcal{O}, \mathcal{T}^{\mathrm{op}}) \simeq \Delta^0 & \xrightarrow{\quad * \quad} & \mathrm{Fun}_{\mathcal{T}}(\mathcal{O}, \underline{\mathbf{Cat}}_{\mathcal{T}}) \simeq \mathrm{Fun}(\mathcal{O}, \mathbf{Cat}). \end{array}$$

This shows the first part of (3), and the second follows since we have a comparison $\mathcal{T}$-functor that we just proved is an equivalence fiberwise. The claim of (4) (i.e., that μ promotes to an equivalence of $(\infty, 2)$-categories) then follows since μ clearly respects cotensors by ∞-categories (cf. Construction 2.6.5). ☐

5.2.10. **Theorem.** *Suppose $\mathcal{O}^{\otimes}$ is a unital $\mathcal{T}$-∞-operad and $\mathcal{C}^{\otimes}$ is a $\mathcal{O}$-monoidal $\mathcal{T}$-∞-category. Then we have a canonical equivalence of $\mathcal{T}$-∞-categories*

$$\underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{O}_0, \mathcal{C}) \xrightarrow{\simeq} \underline{\mathrm{Fun}}_{/\mathcal{O},\mathcal{T}}(\mathcal{O}, \mathcal{C})^{(1,\mathcal{T})/}.$$

Proof. By the usual reduction, it will suffice to prove the statement without the 'underlining'. Our strategy is to replace $\mathcal{O}_0^{\otimes}$ by its $\mathcal{O}_0$-monoidal envelope and then invoke Proposition 5.2.9(4). We first identify $\mathrm{Env}_{\mathcal{O}_0,\mathcal{T}}(\mathcal{O}_0)^{\otimes} = \mathrm{Ar}_{\mathcal{T}}^{act}(\mathcal{O}_0^{\otimes})$ in simpler terms. Let

$$\lambda : \mathcal{O} \times \Delta^1 \longrightarrow \mathrm{Ar}_{\mathcal{T}}^{act}(\mathcal{O}_0^{\otimes}) \times_{\mathcal{O}_0^{\otimes}} \mathcal{O}$$

be the $\mathcal{T}$-functor which for $x \in \mathcal{O}_V$ sends $(x, 0) \longrightarrow (x, 1)$ to the evident morphism $[0_V \to x] \longrightarrow \mathrm{id}_x$ of active arrows. More precisely, we may define the adjoint of λ projecting to $\mathrm{Ar}_{\mathcal{T}}^{act}(\mathcal{O}_0^{\otimes})$ as the composite

$$\mathcal{O} \times \Delta^1 \times \Delta^1 \xrightarrow{h} \mathcal{O}^{\trianglelefteq} \xrightarrow{\omega_{\mathcal{O}}} \mathcal{O}_0^{\otimes},$$

where to define h, we regard $\mathcal{O} \times (\Delta^1 \times \Delta^1)$ as fibered over $\mathcal{T}^{\mathrm{op}} \times \Delta^1$ via the structure map π for $\mathcal{O}$ and $(i, j) \mapsto \max(i, j)$, and let h be given by $(\pi, \mathrm{pr}_{\mathcal{O}})$ under the defining universal property of the $\mathcal{T}$-join (cf. [Sha21a, Prop. 4.3]). We then let

$$\overline{\lambda} : \mathrm{Ar}_{\mathcal{T}}(\mathcal{O}) \times \Delta^1 \longrightarrow \mathrm{Ar}_{\mathcal{T}}^{act}(\mathcal{O}_0^{\otimes}) \times_{\mathcal{O}_0^{\otimes}} \mathcal{O}$$

be the induced morphism of $\mathcal{T}$-cocartesian fibrations over $\mathcal{O}$ extending λ under the equivalence of [Sha21b, Ex. 3.8]. We claim that $\overline{\lambda}$ is an equivalence, for which it suffices to check fiberwise. But for every $x \in \mathcal{O}_V$, we have that λ_x is essentially surjective in view of the unital assumption on $\mathcal{O}^{\otimes}$ (since the active edges must be of the form $[f : x' \to x]$ in $\mathcal{O}_V$ or $[0_V \to x]$ factoring through some f), and an easy computation of mapping spaces shows that λ_x is also fully faithful.

By similar reasoning, we also see that the composition

$$\mathcal{O} \times \{0\} \subset \mathcal{O} \times \Delta^1 \longrightarrow \mathrm{Ar}_{\mathcal{T}}(\mathcal{O}) \times \Delta^1 \xrightarrow{\simeq} \mathrm{Ar}_{\mathcal{T}}^{act}(\mathcal{O}_0^{\otimes}) \times_{\mathcal{O}_0^{\otimes}} \mathcal{O}$$

identifies with the unit map for $\mathrm{Env}_{\mathcal{O}_0,\mathcal{T}}(\mathcal{O}_0)^{\otimes}$. Now let $\mathcal{E} : \mathcal{O} \longrightarrow \mathbf{Cat}$ be the functor obtained by straightening $\mathrm{ev}_1 : \mathrm{Ar}_{\mathcal{T}}(\mathcal{O}) \longrightarrow \mathcal{O}$. We have shown that under the correspondence of Proposition 5.2.9, $\mathrm{Env}_{\mathcal{O}_0,\mathcal{T}}(\mathcal{O}_0)^{\otimes}$ straightens to $\Delta^1 \times \mathcal{E}$. In the notation of that proposition, consider the pullback square

$$\begin{array}{ccc} \mathrm{Nat}_*(\Delta^1 \times \mathcal{E}, f_{\mathcal{C}}) & \longrightarrow & \mathrm{Nat}(\Delta^1 \times \mathcal{E}, f_{\mathcal{C}}) \\ \downarrow & & \downarrow \\ \Delta^0 & \longrightarrow & \mathrm{Nat}(\mathcal{E}, f_{\mathcal{C}}). \end{array}$$

Using the universal property of the free $\mathcal{T}$-cocartesian fibration, we deduce an equivalence

$$\mathrm{Nat}_*(\Delta^1 \times \mathcal{E}, f_{\mathcal{C}}) \simeq \mathrm{Fun}_{/\mathcal{O},\mathcal{T}}(\mathcal{O}, \mathcal{C})^{(1,\mathcal{T})/}.$$

We may now conclude using Proposition 5.2.9(4). □

5.2.11. **Theorem.** *Let $\mathcal{O}^{\otimes}$ be a unital $\mathcal{T}$-∞-operad and let $p : \mathcal{C}^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ be an $\mathcal{O}$-monoidal $\mathcal{T}$-∞-category.*

(1) The $\mathcal{O}$-algebra $1^{\otimes}$ of Proposition 5.2.8 is an initial object of $\mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{C})$.
(2) $\underline{\mathbf{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{C})$ admits a $\mathcal{T}$-initial object given fiberwise by $(1^{\otimes})_{\underline{V}}$.

Proof. Since units are stable under base-change, it suffices to prove the first assertion. Let $1^{\otimes}_{un} : \mathcal{O}^{\otimes}_0 \longrightarrow \mathcal{C}^{\otimes}$ be the unique morphism of $\mathcal{T}$-∞-operads over $\mathcal{O}^{\otimes}$ that sends all edges in $\mathcal{O}^{\otimes}_0$ to p-cocartesian edges in $\mathcal{C}^{\otimes}$ (so $1^{\otimes}_{un}$ extends $* : \mathcal{T}^{\mathrm{op}} \longrightarrow \mathcal{C}^{\otimes}$ under the equivalence of Lemma 5.2.7). Then $1^{\otimes}_{un}$ corresponds to $1 \in \mathrm{Fun}_{/\mathcal{O},\mathcal{T}}(\mathcal{O},\mathcal{C})^{(1,\mathcal{T})/}$ under the equivalence of Theorem 5.2.10 and is hence an initial object of $\mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{O}_0,\mathcal{C})$.

Let $i : \mathcal{O}^{\otimes}_0 \longrightarrow \mathcal{O}^{\otimes}$ denote the inclusion. It will suffice to show that the left adjoint $i_!$ to the the forgetful functor $i^* : \mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{C}) \longrightarrow \mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{O}_0,\mathcal{C})$ is defined on $1^{\otimes}_{un}$ and sends $1^{\otimes}_{un}$ to $1^{\otimes}$. Consider the factorization of i through its $\mathcal{O}$-monoidal envelope

$$\mathcal{O}^{\otimes}_0 \xrightarrow{\iota} \mathrm{Env}_{\mathcal{O},\mathcal{T}}(\mathcal{O}_0)^{\otimes} = \mathcal{O}^{\otimes}_0 \times_{\mathcal{O}^{\otimes}} \mathrm{Ar}^{act}_{\mathcal{T}}(\mathcal{O}^{\otimes}) \xrightarrow{\mathrm{ev}_1} \mathcal{O}^{\otimes}$$

and the resulting sequence of adjunctions

$$\begin{array}{ccc} \mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{O}_0,\mathcal{C}) \simeq \mathrm{Fun}^{\otimes}_{\mathcal{O},\mathcal{T}}(\mathrm{Env}_{\mathcal{O},\mathcal{T}}(\mathcal{O}_0),\mathcal{C}) & \underset{\iota^*}{\overset{\iota_!}{\rightleftarrows}} & \mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathrm{Env}_{\mathcal{O},\mathcal{T}}(\mathcal{O}_0),\mathcal{C}) \\ & {\scriptstyle i_!}\searrow \ \nwarrow{\scriptstyle i^*} & (\mathrm{ev}_1)^* \uparrow \ \downarrow (\mathrm{ev}_1)_! \\ & & \mathbf{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{C}) \end{array}$$

where the dotted left adjoints are not necessarily defined. Observe that for every orbit $V \in \mathcal{T}$, the fiber $\mathrm{Env}_{\mathcal{O},\mathcal{T}}(\mathcal{O}_0)^{\otimes}_V$ admits an initial object given by id_{0_V}, and these assemble to define a $\mathcal{T}$-initial object of $\mathrm{Env}_{\mathcal{O},\mathcal{T}}(\mathcal{O}_0)^{\otimes}$. By Lemma 5.2.7, the $\mathcal{O}$-monoidal $\mathcal{T}$-functor $1^{\otimes} \circ \mathrm{ev}_1$ restricts to $1^{\otimes}_{un}$ as they both send *all* edges to p-cocartesian edges and extend $*$, so $\iota_!(1^{\otimes}_{un}) \simeq 1^{\otimes} \circ \mathrm{ev}_1$. Now observe that for every $x \in \mathcal{O}^{\otimes}_V$, the unique map $0_V \to x$ is active and is an initial object in the fiber $\mathrm{Env}_{\mathcal{O},\mathcal{T}}(\mathcal{O}_0)^{\otimes} \times_{\mathcal{O}^{\otimes}} \{x\}$. Consequently, the ordinary left Kan extension of $1^{\otimes} \circ \mathrm{ev}_1$ along ev_1 exists and is computed by $1^{\otimes}$ itself. Since the ordinary left Kan extension is an $\mathcal{O}$-algebra in this case, we conclude that $(\mathrm{ev}_1)_!(1^{\otimes} \circ \mathrm{ev}_1) \simeq 1^{\otimes}$ and hence $i_!(1^{\otimes}_{un}) \simeq 1^{\otimes}$. □

5.3. **Indexed coproducts in the $\mathcal{T}$-symmetric monoidal case.** We identify finite $\mathcal{T}$-indexed coproducts with tensor products in the case of a $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-category $\mathcal{C}$, following the strategy of [Lur17, §3.2.4]. To precisely articulate this identification, we first discuss how to equip $\underline{\mathbf{CAlg}}_{\mathcal{T}}(\mathcal{C})$ with a $\mathcal{T}$-symmetric monoidal structure.

5.3.1. **Construction.** We define the smash product $\mathcal{T}$-functor

$$\wedge : \underline{\mathbf{F}}_{\mathcal{T},*} \times_{\mathcal{T}^{\mathrm{op}}} \underline{\mathbf{F}}_{\mathcal{T},*} \longrightarrow \underline{\mathbf{F}}_{\mathcal{T},*}, \quad ([U_+ \to V],[U'_+ \to V]) \mapsto [(U \times_V U')_+ \mapsto V]$$

as follows. Recall that given an ∞-category $\mathcal{D}$ with finite products, we can define the smash product functor $\wedge : \mathcal{D}_* \times \mathcal{D}_* \longrightarrow \mathcal{D}_*$ as the composition of functors

$$\mathcal{D}_* \times \mathcal{D}_* \subset \mathcal{D}^{\Delta^1} \times \mathcal{D}^{\Delta^1} \xrightarrow{\times} \mathcal{D}^{\Delta^1 \times \Delta^1} \xrightarrow{\min_!} \mathcal{D}^{\Delta^1} \xrightarrow{(d^2)_*} \mathcal{D}^{\Lambda^2_0} \xrightarrow{\mathrm{colim}} \mathcal{D}^{(\Lambda^2_0)^{\triangleright}} \xrightarrow{\mathrm{ev}_{\{2\}^{\triangleright}}} \mathcal{D}$$

provided the functors $\min_!$ and colim exist pointwise on objects $(* \to x, * \to y)$ and $(* \leftarrow x \vee y \to x \times y)$, as they then extend to partially defined left adjoints so that the composition exists. If we then have a presheaf $\mathcal{D}_{\bullet} : \mathcal{T}^{\mathrm{op}} \longrightarrow \mathbf{Cat}$ such that for every $\alpha : V \longrightarrow W$ in $\mathcal{T}$, $\alpha^* : \mathcal{D}_W \longrightarrow \mathcal{D}_V$ preserves finite products, wedge sums, and cofibers $(x \times y)/(x \vee y)$, it follows from the existence theorem for relative adjunctions ([Lur17, Prop. 7.3.2.6] and [Lur17, Prop. 7.3.2.11]) that we obtain a $\mathcal{T}$-functor

$$\wedge : \underline{\mathcal{D}_*} \times_{\mathcal{T}^{\mathrm{op}}} \underline{\mathcal{D}_*} \longrightarrow \underline{\mathcal{D}_*}$$

given fiberwise by formation of smash products, where $\underline{\mathcal{D}_*}$ is the unstraightening of the pointed presheaf $\mathcal{D}_{\bullet,*}$.

5.3.2. **Definition.** Let $\mathcal{O}^\otimes, \mathcal{P}^\otimes, \mathcal{Q}^\otimes$ be $\mathcal{T}$-∞-operads. We say that a $\mathcal{T}$-functor $F : \mathcal{O}^\otimes \times_{\mathcal{T}^{op}} \mathcal{P}^\otimes \longrightarrow \mathcal{Q}^\otimes$ is a *bifunctor of* $\mathcal{T}$-∞*-operads* if it sends pairs of inert edges to inert edges and the diagram

$$\begin{array}{ccc} \mathcal{O}^\otimes \times_{\mathcal{T}^{op}} \mathcal{P}^\otimes & \xrightarrow{F} & \mathcal{Q}^\otimes \\ \downarrow & & \downarrow \\ \underline{\mathbf{F}}_{\mathcal{T},*} \times_{\mathcal{T}^{op}} \underline{\mathbf{F}}_{\mathcal{T},*} & \xrightarrow{\wedge} & \underline{\mathbf{F}}_{\mathcal{T},*} \end{array}$$

is homotopy commutative.[12]

5.3.3. **Variant.** By the same construction as in Construction 5.3.1, we have a smash product $\mathbf{F}_{\mathcal{T}}^{op}$-functor

$$\wedge : \underline{\mathbf{F}}_{\mathcal{T},*}^{\mathrm{big}} \times_{\mathbf{F}_{\mathcal{T}}^{op}} \underline{\mathbf{F}}_{\mathcal{T},*}^{\mathrm{big}} \longrightarrow \underline{\mathbf{F}}_{\mathcal{T},*}^{\mathrm{big}}$$

that can be chosen to extend the smash product on $\underline{\mathbf{F}}_{\mathcal{T},*}$. Likewise, we have the analogous definition of a bifunctor of big $\mathcal{T}$-∞-operads, and the datum of one determines the other essentially uniquely under the correspondence of Corollary 2.7.5.

5.3.4. **Theorem-Construction.** Suppose $F : \mathcal{O}^\otimes \times_{\mathcal{T}^{op}} \mathcal{P}^\otimes \longrightarrow \mathcal{Q}^\otimes$ is a bifunctor of $\mathcal{T}$-∞-operads and let the $\mathcal{T}$-functor

$$P : \mathcal{O}^\otimes \times_{\mathcal{T}^{op}} \mathrm{Ar}(\mathcal{T}^{op}) \longrightarrow \mathcal{O}^\otimes, \quad (x, V \xleftarrow{\beta} W) \mapsto \beta^*(x)$$

be a choice of cocartesian pushforward. Consider the spans of marked simplicial sets

$$(\mathcal{O}^\otimes, \mathrm{Ne}) \xleftarrow{\pi} (\mathcal{O}^\otimes, \mathrm{Ne}) \times_{\mathcal{T}^{op}} \mathrm{Ar}(\mathcal{T}^{op})^\sharp \times_{\mathcal{T}^{op}} (\mathcal{P}^\otimes, \mathrm{Ne}) \xrightarrow{G} (\mathcal{Q}^\otimes, \mathrm{Ne}),$$

$$(\mathcal{O}^\otimes)^\sharp \xleftarrow{\pi} (\mathcal{O}^\otimes)^\sharp \times_{\mathcal{T}^{op}} \mathrm{Ar}(\mathcal{T}^{op})^\sharp \times_{\mathcal{T}^{op}} (\mathcal{P}^\otimes, \mathrm{Ne}) \xrightarrow{G} (\mathcal{Q}^\otimes)^\sharp,$$

where $G = F \circ (P \times \mathrm{id}_{\mathcal{P}^\otimes})$ and π is the projection to $\mathcal{O}^\otimes$. Then these spans determine Quillen adjunctions

$$G_! \pi^* : \mathbf{sSet}^+_{/(\mathcal{O}^\otimes, \mathrm{Ne})} \rightleftarrows \mathbf{sSet}^+_{/(\mathcal{Q}^\otimes, \mathrm{Ne})} : \pi_* G^*, \qquad G_! \pi^* : \mathbf{sSet}^+_{/\mathcal{O}^\otimes} \rightleftarrows \mathbf{sSet}^+_{/\mathcal{Q}^\otimes} : \pi_* G^*$$

with respect to the $\mathcal{T}$-operadic model structures and $\mathcal{T}$-monoidal model structures. Given a fibration $\mathcal{C}^\otimes \longrightarrow \mathcal{Q}^\otimes$ of $\mathcal{T}$-∞-operads, we then let

$$\underline{\mathbf{Alg}}_{\mathcal{Q},\mathcal{T}}(\mathcal{P}, \mathcal{C})^\otimes \longrightarrow \mathcal{O}^\otimes$$

denote the resulting fibration of $\mathcal{T}$-∞-operads given by $\pi_* G^*(\mathcal{C}^\otimes, \mathrm{Ne})$.[13]

If $\mathcal{C}^\otimes$ is $\mathcal{Q}$-monoidal, then $\underline{\mathbf{Alg}}_{\mathcal{Q},\mathcal{T}}(\mathcal{P}, \mathcal{C})^\otimes$ is $\mathcal{O}$-monoidal, and has cocartesian edges marked as in $\pi_* G^*({}_\natural \mathcal{C}^\otimes)$.

Proof. Note that the underlying simplicial sets of $\pi_* G^*(-)$ are the same regardless of whether we work over $(\mathcal{Q}^\otimes, \mathrm{Ne})$ or $(\mathcal{Q}^\otimes)^\sharp$. We first establish the assertion on the Quillen adjunction between $\mathcal{T}$-operadic model structures. For the proof, it will be convenient to pass to big $\mathcal{T}$-∞-operads (cf. Variant 5.3.3). Let

$$\widetilde{F} : \widetilde{\mathcal{O}}^\otimes \times_{\mathbf{F}_{\mathcal{T}}^{op}} \widetilde{\mathcal{P}}^\otimes \longrightarrow \widetilde{\mathcal{Q}}^\otimes$$

be the bifunctor of big $\mathcal{T}$-∞-operads extending F, let the $\mathbf{F}_{\mathcal{T}}$-functor

$$\widetilde{P} : \widetilde{\mathcal{O}}^\otimes \times_{\mathbf{F}_{\mathcal{T}}^{op}} \mathrm{Ar}(\mathbf{F}_{\mathcal{T}}^{op}) \longrightarrow \widetilde{\mathcal{O}}^\otimes$$

be a choice of cocartesian pushforward over $\mathbf{F}_{\mathcal{T}}^{op}$ extending P, let $\widetilde{G} = \widetilde{F} \circ (\widetilde{P} \times \mathrm{id}_{\widetilde{\mathcal{P}}^\otimes})$, and consider the span of marked simplicial sets

$$(\widetilde{\mathcal{O}}^\otimes, \mathrm{Ne}) \xleftarrow{\widetilde{\pi}} (\widetilde{\mathcal{O}}^\otimes, \mathrm{Ne}) \times_{\mathbf{F}_{\mathcal{T}}^{op}} \mathrm{Ar}(\mathbf{F}_{\mathcal{T}}^{op})^\sharp \times_{\mathbf{F}_{\mathcal{T}}^{op}} (\widetilde{\mathcal{P}}^\otimes, \mathrm{Ne}) \xrightarrow{\widetilde{G}} (\widetilde{\mathcal{Q}}^\otimes, \mathrm{Ne}).$$

We claim that this span satisfies the hypotheses of [Lur17, Thm. B.4.2] with respect to the categorical patterns $\widetilde{\mathfrak{P}}_{\mathcal{O}}$ and $\widetilde{\mathfrak{P}}_{\mathcal{Q}}$ of Definition 2.7.3. (2) is clear and (3) is vacuous. By [Lur09, Cor. 2.4.7.17], the source functor $\mathrm{ev}_0 : \mathrm{Ar}(\mathbf{F}_{\mathcal{T}}^{op}) \times_{\mathbf{F}_{\mathcal{T}}^{op}} \widetilde{P}^\otimes \longrightarrow \mathbf{F}_{\mathcal{T}}^{op}$ is a cartesian fibration, so the pullback $\widetilde{\pi}$ is a cartesian fibration.

[12] If $\mathcal{T} = *$, then the smash product for $\mathbf{Fin}_*$ can be defined without the ambiguity of a contractible space of choices. Therefore, one can choose the square to strictly commute in $\mathbf{sSet}^+_{/(\mathbf{Fin}_*, \mathrm{Ne})}$ for the non-parametrized definition of a bifunctor of ∞-operads as in [Lur17, Def. 2.2.5.3].

[13] Beware that the notation $\underline{\mathbf{Alg}}_{\mathcal{Q},\mathcal{T}}(\mathcal{P}, \mathcal{C})^\otimes$ hides the dependence of the structure map $\mathcal{P}^\otimes \longrightarrow \mathcal{Q}^\otimes$ on the choice of parameter in $\mathcal{O}^\otimes$.

This proves (1) and (4). Moreover, an edge in $\widetilde{\mathcal{O}}^{\otimes} \times_{\mathbf{F}_{\mathcal{T}}^{\mathrm{op}}} \mathrm{Ar}(\mathbf{F}_{\mathcal{T}}^{\mathrm{op}}) \times_{\mathbf{F}_{\mathcal{T}}^{\mathrm{op}}} \widetilde{\mathcal{P}}^{\otimes}$ is $\widetilde{\pi}$-cartesian if and only if its projection to $\widetilde{\mathcal{P}}^{\otimes}$ is an equivalence, which implies (7).

Now let $f_{x,\phi,\Sigma} : n^{\lhd} \longrightarrow \widetilde{\mathcal{O}}^{\otimes}$ be as in Definition 2.7.3, so that $\phi : U \longrightarrow V$ is a morphism in $\mathbf{F}_{\mathcal{T}}$, $\Sigma = \{\sigma_1, ..., \sigma_n\}$ is a collection of commutative squares

$$\begin{array}{ccc} U_i & \xrightarrow{\alpha_i} & U \\ \downarrow{\scriptstyle \phi_i} & & \downarrow{\scriptstyle \phi} \\ V_i & \xrightarrow{\beta_i} & V \end{array}$$

such that α_i and $U_i \longrightarrow V_i \times_V U$ are summand inclusions and $U \simeq \coprod_{1 \leq i \leq n} U_i$, $f(v) = x$, and each morphism $\overline{\chi}_i := f(v \longrightarrow i) : x \longrightarrow x_i := f(i)$ is an inert edge covering $\chi_{\sigma_i} : [U_+ \to V] \mapsto [(U_i)_+ \to V_i]$ in $\underline{\mathbf{F}}_{\mathcal{T},*}^{\mathrm{big}}$. We first prove (5) by showing that the restriction

$$n^{\lhd} \times_{\mathbf{F}_{\mathcal{T}}^{\mathrm{op}}} \mathrm{Ar}(\mathbf{F}_{\mathcal{T}}^{\mathrm{op}}) \times_{\mathbf{F}_{\mathcal{T}}^{\mathrm{op}}} \widetilde{\mathcal{P}}^{\otimes} \longrightarrow n^{\lhd}$$

of π along $f_{x,\phi,\Sigma}$ is a cocartesian fibration. In fact, by [Lur17, Lem. 6.1.1.1], for any cocartesian fibration $\mathcal{X} \longrightarrow \mathbf{F}_{\mathcal{T}}^{\mathrm{op}}$, the source functor $\mathrm{ev}_0 : \mathrm{Ar}(\mathbf{F}_{\mathcal{T}}^{\mathrm{op}}) \times_{\mathbf{F}_{\mathcal{T}}^{\mathrm{op}}} \mathcal{X} \longrightarrow \mathbf{F}_{\mathcal{T}}^{\mathrm{op}}$ is a cocartesian fibration, with an edge

$$\left(\begin{array}{ccc} V & \longleftarrow & V' \\ \uparrow & & \uparrow \\ W & \longleftarrow & W' \end{array} , \; x \longrightarrow y \right)$$

cocartesian if and only if the square in $\mathbf{F}_{\mathcal{T}}$ is a pullback square and $x \longrightarrow y$ is a cocartesian edge. Next, let

$$s : n^{\lhd} \longrightarrow n^{\lhd} \times_{\mathbf{F}_{\mathcal{T}}^{\mathrm{op}}} \mathrm{Ar}(\mathbf{F}_{\mathcal{T}}^{\mathrm{op}}) \times_{\mathbf{F}_{\mathcal{T}}^{\mathrm{op}}} \widetilde{\mathcal{P}}^{\otimes}$$

be a cocartesian section determined by $s(v) = (V \xleftarrow{\gamma} W, y \in \widetilde{\mathcal{P}}^{\otimes}_{[U'_+ \to W]})$, so that $s(i) = (V_i \xleftarrow{\gamma_i} W_i := W \times_V V_i, y_i)$ for $y \longrightarrow y_i$ an inert edge lifting $W_i \longrightarrow W$. Let $z = \widetilde{F}(\gamma^* x, y)$, let σ'_i be

$$\begin{array}{ccc} U_i \times_V U' & \longrightarrow & U \times_V U' \\ \downarrow & & \downarrow{\scriptstyle \phi'} \\ W_i & \longrightarrow & W, \end{array}$$

and let $\Sigma' = \{\sigma'_1, ..., \sigma'_n\}$. Then a chase of the definitions shows that the composition $\widetilde{F} \circ \widetilde{P} \circ f_{x,\phi,\Sigma}$ is of the form $f_{z,\phi',\Sigma'}$, which shows (6). Finally, (8) follows from the right cancellation property of inert edges. This completes the verification of the hypotheses of [Lur17, Thm. B.4.2]. We then deduce the theorem in question by means of Proposition 2.7.4 and Corollary 2.7.5. Finally, repeating this analysis for the other span proves the assertions regarding the monoidality of the construction. □

5.3.5. **Proposition.** *Let $F : \mathcal{O}^{\otimes} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{P}^{\otimes} \longrightarrow \mathcal{Q}^{\otimes}$ be a bifunctor of $\mathcal{T}$-∞-operads and let $\mathcal{C}^{\otimes} \longrightarrow \mathcal{Q}^{\otimes}$ be a fibration of $\mathcal{T}$-∞-operads. We then have the following properties of the construction $\underline{\mathbf{Alg}}_{\mathcal{Q},\mathcal{T}}(\mathcal{P}, \mathcal{C})^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$:*

(1) *For every object $x \in \mathcal{O}$ over $V \in \mathcal{T}^{\mathrm{op}}$, the parametrized restriction*

$$F_{\underline{x}} : \underline{x} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{P}^{\otimes} \longrightarrow (\mathcal{Q}^{\otimes})_{\underline{V}}$$

is a morphism of $\mathcal{T}^{/V}$-∞-operads, and we obtain a canonical equivalence of $\mathcal{T}^{/V}$-∞-categories

$$\underline{\mathbf{Alg}}_{\mathcal{Q},\mathcal{T}}(\mathcal{P}, \mathcal{C})^{\otimes} \times_{\mathcal{O}^{\otimes}} \underline{x} \simeq \underline{\mathbf{Alg}}_{\mathcal{Q}_{\underline{V}},\mathcal{T}^{/V}}(\mathcal{P}_{\underline{V}}, \mathcal{C}_{\underline{V}}).$$

Similarly, for every cocartesian section $\tau : \mathcal{T}^{\mathrm{op}} \longrightarrow \mathcal{O}$, we have a canonical equivalence of $\mathcal{T}$-∞-categories

$$\underline{\mathbf{Alg}}_{\mathcal{Q},\mathcal{T}}(\mathcal{P}, \mathcal{C})^{\otimes} \times_{\mathcal{O}^{\otimes},\tau} \mathcal{T}^{\mathrm{op}} \simeq \underline{\mathbf{Alg}}_{\mathcal{Q},\mathcal{T}}(\mathcal{P}, \mathcal{C}).$$

(2) *For every object $y \in \mathcal{P}$ over $V \in \mathcal{T}^{\mathrm{op}}$, the parametrized restriction*

$$F_{\underline{y}} : \mathcal{O}^{\otimes} \times_{\mathcal{T}^{\mathrm{op}}} \underline{y} \longrightarrow (\mathcal{Q}^{\otimes})_{\underline{V}}$$

is a morphism of $\mathcal{T}^{/V}$-∞-operads, and 'evaluation at y' furnishes a commutative square of $\mathcal{T}^{/V}$-∞-operads

$$\begin{array}{ccc}
(\underline{\mathbf{Alg}}_{\mathcal{Q},\mathcal{T}}(\mathcal{P},\mathcal{C})^{\otimes})_{\underline{V}} & \xrightarrow{\mathrm{ev}_y} & (\mathcal{C}^{\otimes})_{\underline{V}} \\
\downarrow & & \downarrow \\
(\mathcal{O}^{\otimes})_{\underline{V}} \simeq \mathcal{O}^{\otimes} \times_{\mathcal{T}^{\mathrm{op}}} \underline{y} & \xrightarrow{F_{\underline{y}}} & (\mathcal{Q}^{\otimes})_{\underline{V}}.
\end{array}$$

Similarly, for every cocartesian section $\tau : \mathcal{T}^{\mathrm{op}} \longrightarrow \mathcal{P}$, we have a morphism of $\mathcal{T}$-∞-operads

$$\mathrm{ev}_{\tau} : \underline{\mathbf{Alg}}_{\mathcal{Q},\mathcal{T}}(\mathcal{P},\mathcal{C})^{\otimes} \longrightarrow \mathcal{C}^{\otimes}$$

covering $F_{\tau} : \mathcal{O}^{\otimes} \longrightarrow \mathcal{Q}^{\otimes}$ and given fiberwise by evaluation at $\tau(V)$.

(3) If $\mathcal{C}^{\otimes}$ is $\mathcal{Q}$-monoidal (so that $\underline{\mathbf{Alg}}_{\mathcal{Q},\mathcal{T}}(\mathcal{P},\mathcal{C})^{\otimes}$ is $\mathcal{O}$-monoidal), then ev_y *and* ev_{τ} *preserve cocartesian edges.*

Proof. (1): We prove the assertion about x – that for τ will hold by the same reasoning. We have a commutative diagram

$$\begin{array}{ccccc}
\underline{x} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{P}^{\otimes} & \longrightarrow & \mathcal{O}^{\otimes} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{P}^{\otimes} & \xrightarrow{F} & \mathcal{Q}^{\otimes} \\
\downarrow & & \downarrow & & \downarrow \\
(\mathcal{T}^{/V})^{\mathrm{op}} \times_{\mathcal{T}^{\mathrm{op}}} \underline{\mathbf{F}}_{\mathcal{T},*} & \longrightarrow & \underline{\mathbf{F}}_{\mathcal{T},*} \times_{\mathcal{T}^{\mathrm{op}}} \underline{\mathbf{F}}_{\mathcal{T},*} & \xrightarrow{\wedge} & \underline{\mathbf{F}}_{\mathcal{T},*}
\end{array}$$

where the outer square induces the $\mathcal{T}^{/V}$-functor $F_{\underline{x}}$. The definition of a bifunctor of $\mathcal{T}$-∞-operads then immediately shows that $F_{\underline{x}}$ is a morphism of $\mathcal{T}^{/V}$-∞-operads. Next, consider the commutative diagram

$$\begin{array}{ccccccc}
 & & \mathrm{Ar}(\underline{x}) \times_{\underline{x}} (\underline{x} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{P}^{\otimes}) & & & & \\
 & \swarrow^{\mathrm{ev}_0} & \downarrow{\scriptstyle \rho}\,\simeq & \searrow^{\mathrm{pr}} & & & \\
\underline{x} & \xleftarrow{\pi} & \underline{x} \times_{\mathcal{T}^{\mathrm{op}}} \mathrm{Ar}(\mathcal{T}^{\mathrm{op}}) \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{P}^{\otimes} & \xrightarrow{P \times \mathrm{id}} & \underline{x} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{P}^{\otimes} & \xrightarrow{F_{\underline{x}}} & \mathcal{Q}^{\otimes}_{\underline{V}} \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
\mathcal{O}^{\otimes} & \xleftarrow{\pi} & \mathcal{O}^{\otimes} \times_{\mathcal{T}^{\mathrm{op}}} \mathrm{Ar}(\mathcal{T}^{\mathrm{op}}) \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{P}^{\otimes} & \xrightarrow{P \times \mathrm{id}} & \mathcal{O}^{\otimes} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{P}^{\otimes} & \xrightarrow{F} & \mathcal{Q}^{\otimes}
\end{array}$$

where the functor ρ is the trivial fibration used in the definition of the cocartesian pushforward. Using the variant of [Sha21b, Lem. 4.8] for algebra maps, after marking appropriately this diagram induces a comparison $\mathcal{T}^{/V}$-functor

$$\underline{\mathbf{Alg}}_{\mathcal{Q},\mathcal{T}}(\mathcal{P},\mathcal{C})^{\otimes} \times_{\mathcal{O}^{\otimes}} \underline{x} \longrightarrow \underline{\mathbf{Alg}}_{\mathcal{Q}_{\underline{V}},\mathcal{T}^{/V}}(\mathcal{P}_{\underline{V}},\mathcal{C}_{\underline{V}}),$$

which by [Sha21a, Lem. 2.27] is an equivalence.

(2): By the same logic as in (1), $F_{\underline{y}}$ is a morphism of $\mathcal{T}^{/V}$-∞-operads. Using the compatibility of the construction $\underline{\mathbf{Alg}}_{\mathcal{Q},\mathcal{T}}(\mathcal{P},\mathcal{C})^{\otimes} \longrightarrow \mathcal{O}^{\otimes}$ with base-change in $\mathcal{T}$, without loss of generality we may replace $\mathcal{T}^{/V}$ with $\mathcal{T}$ and suppose $y \in \mathcal{P}$ lies over a final object in $\mathcal{T}$. Choosing a section σ of the trivial Kan fibration $\underline{y} \xrightarrow{\simeq} \mathcal{T}^{\mathrm{op}}$, let $j = (\mathrm{id}, \iota, \sigma) : \mathcal{O}^{\otimes} \longrightarrow \mathcal{O}^{\otimes} \times_{\mathcal{T}^{\mathrm{op}}} \mathrm{Ar}(\mathcal{T}^{\mathrm{op}}) \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{P}^{\otimes}$ and consider the morphism of spans

$$\begin{array}{ccccccc}
 & & \mathcal{O}^{\otimes} & & & & \\
 & \swarrow^{=} & \downarrow{\scriptstyle j} & & \searrow^{F_{\underline{y}}\sigma} & & \\
\mathcal{O}^{\otimes} & \xleftarrow{\pi} & \mathcal{O}^{\otimes} \times_{\mathcal{T}^{\mathrm{op}}} \mathrm{Ar}(\mathcal{T}^{\mathrm{op}}) \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{P}^{\otimes} & \xrightarrow{P \times \mathrm{id}} & \mathcal{O}^{\otimes} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{P}^{\otimes} & \xrightarrow{F} & \mathcal{Q}^{\otimes}.
\end{array}$$

Noting that j respects markings for the first span in Theorem-Construction 5.3.4, we then see that j induces the desired morphism of $\mathcal{T}$-∞-operads $\underline{\mathbf{Alg}}_{\mathcal{Q},\mathcal{T}}(\mathcal{P},\mathcal{C})^{\otimes} \longrightarrow \mathcal{O}^{\otimes} \times_{\mathcal{Q}^{\otimes}} \mathcal{C}^{\otimes}$.

(3): This follows from the proof of (2) since the functor j also respects markings for the second span in Theorem-Construction 5.3.4. □

We now specialize to the bifunctor $\wedge : \underline{\mathbf{F}}_{\mathcal{T},*} \times_{\mathcal{T}^{\mathrm{op}}} \underline{\mathbf{F}}_{\mathcal{T},*} \longrightarrow \underline{\mathbf{F}}_{\mathcal{T},*}$. Fix a choice of cocartesian pushforward $P : \underline{\mathbf{F}}_{\mathcal{T},*} \times_{\mathcal{T}^{\mathrm{op}}} \mathrm{Ar}(\mathcal{T}^{\mathrm{op}}) \longrightarrow \underline{\mathbf{F}}_{\mathcal{T},*}$ and also write

$$\wedge : \underline{\mathbf{F}}_{\mathcal{T},*} \times^{\mathrm{lax}}_{\mathcal{T}^{\mathrm{op}}} \underline{\mathbf{F}}_{\mathcal{T},*} := \underline{\mathbf{F}}_{\mathcal{T},*} \times_{\mathcal{T}^{\mathrm{op}}} \mathrm{Ar}(\mathcal{T}^{\mathrm{op}}) \times_{\mathcal{T}^{\mathrm{op}}} \underline{\mathbf{F}}_{\mathcal{T},*} \longrightarrow \underline{\mathbf{F}}_{\mathcal{T},*}$$

for the composition $\wedge \circ (P \times \mathrm{id})$.

5.3.6. **Construction.** Let $\mathcal{C}^{\otimes}$ be a $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-category. We construct a $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-functor

$$(-)^{\mathrm{can}} : \underline{\mathbf{CAlg}}_{\mathcal{T}}(\mathcal{C})^{\otimes} \longrightarrow \underline{\mathbf{CAlg}}_{\mathcal{T}}(\underline{\mathbf{CAlg}}_{\mathcal{T}}(\mathcal{C}))^{\otimes}$$

that is split by the 'forgetful' evaluation $\mathcal{T}$-functor U of Proposition 5.3.5(2). First observe that we have a commutative diagram of marked simplicial sets

$$\begin{array}{ccccc}
\underline{\mathbf{F}}_{\mathcal{T},*}{}^{\sharp} \times^{\mathrm{lax}}_{\mathcal{T}^{\mathrm{op}}} (\underline{\mathbf{F}}_{\mathcal{T},*}, \mathrm{Ne}) \times^{\mathrm{lax}}_{\mathcal{T}^{\mathrm{op}}} (\underline{\mathbf{F}}_{\mathcal{T},*}, \mathrm{Ne}) & \xrightarrow{\wedge \times^{\mathrm{lax}}_{\mathcal{T}^{\mathrm{op}}} \mathrm{id}} & \underline{\mathbf{F}}_{\mathcal{T},*}{}^{\sharp} \times^{\mathrm{lax}}_{\mathcal{T}^{\mathrm{op}}} (\underline{\mathbf{F}}_{\mathcal{T},*}, \mathrm{Ne}) & \xrightarrow{\wedge} & \underline{\mathbf{F}}_{\mathcal{T},*}{}^{\sharp} \\
\downarrow \mathrm{pr}_{12} & & \downarrow \mathrm{pr}_1 & & \\
\underline{\mathbf{F}}_{\mathcal{T},*}{}^{\sharp} \times^{\mathrm{lax}}_{\mathcal{T}^{\mathrm{op}}} (\underline{\mathbf{F}}_{\mathcal{T},*}, \mathrm{Ne}) & \xrightarrow{\wedge} & \underline{\mathbf{F}}_{\mathcal{T},*}{}^{\sharp} & & \\
\downarrow \mathrm{pr}_1 & & & & \\
\underline{\mathbf{F}}_{\mathcal{T},*}{}^{\sharp} & & & &
\end{array}$$

in which the square is a pullback (here, pr_{12} denotes projection away from the third factor). Also write $\wedge$ for the upper horizontal composite. Then we have that (cf. [Sha21a, Lem. 2.26])

$$(\mathrm{pr}_1)_* \wedge^* \cong (\mathrm{pr}_1)_* \wedge^* (\mathrm{pr}_1)_* \wedge^* : \mathbf{sSet}^+_{/\underline{\mathbf{F}}_{\mathcal{T},*}} \longrightarrow \mathbf{sSet}^+_{/\underline{\mathbf{F}}_{\mathcal{T},*}}, \quad \natural\mathcal{C}^{\otimes} \mapsto \natural\underline{\mathbf{CAlg}}_{\mathcal{T}}(\underline{\mathbf{CAlg}}_{\mathcal{T}}(\mathcal{C}))^{\otimes}.$$

Now consider the morphisms of spans

$$\begin{array}{ccccc}
 & \xleftarrow{\mathrm{pr}_1} & \underline{\mathbf{F}}_{\mathcal{T},*}{}^{\sharp} \times^{\mathrm{lax}}_{\mathcal{T}^{\mathrm{op}}} (\underline{\mathbf{F}}_{\mathcal{T},*}, \mathrm{Ne}) & \xrightarrow{\wedge} & \\
 & & \downarrow \mathrm{id} \times^{\mathrm{lax}}_{\mathcal{T}^{\mathrm{op}}} \mathrm{id} \times^{\mathrm{lax}}_{\mathcal{T}^{\mathrm{op}}} \iota & & \\
\underline{\mathbf{F}}_{\mathcal{T},*}{}^{\sharp} & \xleftarrow{\mathrm{pr}_1} & \underline{\mathbf{F}}_{\mathcal{T},*}{}^{\sharp} \times^{\mathrm{lax}}_{\mathcal{T}^{\mathrm{op}}} (\underline{\mathbf{F}}_{\mathcal{T},*}, \mathrm{Ne}) \times^{\mathrm{lax}}_{\mathcal{T}^{\mathrm{op}}} (\underline{\mathbf{F}}_{\mathcal{T},*}, \mathrm{Ne}) & \xrightarrow{\wedge} & \underline{\mathbf{F}}_{\mathcal{T},*}{}^{\sharp}. \\
 & & \downarrow \mathrm{id} \times^{\mathrm{lax}}_{\mathcal{T}^{\mathrm{op}}} \wedge & & \\
 & \xleftarrow{\mathrm{pr}_1} & \underline{\mathbf{F}}_{\mathcal{T},*}{}^{\sharp} \times^{\mathrm{lax}}_{\mathcal{T}^{\mathrm{op}}} (\underline{\mathbf{F}}_{\mathcal{T},*}, \mathrm{Ne}) & \xrightarrow{\wedge} &
\end{array}$$

Then the lower vertical arrow defines $(-)^{\mathrm{can}}$, and since the upper vertical arrow induces U and the composite is homotopic to the identity, we see that $\mathrm{U} \circ (-)^{\mathrm{can}} \simeq \mathrm{id}$.

5.3.7. **Theorem.** *Let $\mathcal{C}^{\otimes}$ be a $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-category. Then $\underline{\mathbf{CAlg}}_{\mathcal{T}}(\mathcal{C})$ has all finite $\mathcal{T}$-coproducts. Moreover, for any map of finite $\mathcal{T}$-sets $f : U \longrightarrow V$, we have a canonical equivalence*

$$\coprod_f \simeq f_{\otimes} : \underline{\mathbf{CAlg}}_{\mathcal{T}}(\mathcal{C})_U \longrightarrow \underline{\mathbf{CAlg}}_{\mathcal{T}}(\mathcal{C})_V,$$

where $f_{\otimes}$ is furnished by the $\mathcal{T}$-symmetric monoidal structure on $\underline{\mathbf{CAlg}}_{\mathcal{T}}(\mathcal{C})$ of Theorem-Construction 5.3.4.

Proof. Since the base-change condition for left adjoints to the restriction functors $\{f^*\}$ of $\underline{\mathbf{CAlg}}_{\mathcal{T}}(\mathcal{C})$ to furnish finite $\mathcal{T}$-coproducts is already satisfied by the maps $\{f_{\otimes}\}$, it will suffice to construct unit and counit maps exhibiting $f_{\otimes}$ as left adjoint to f^*. Without loss of generality, we may suppose V is an orbit, and after replacing $\mathcal{T}$ by $\mathcal{T}^{/V}$, we may suppose $V = *$ is the final object of $\mathcal{T}$ so that $\underline{\mathbf{CAlg}}_{\mathcal{T}}(\mathcal{C})_V \simeq \mathbf{CAlg}_{\mathcal{T}}(\mathcal{C})$. In addition, by Theorem 5.2.11, $\mathbf{CAlg}_{\mathcal{T}}(\mathcal{C})$ admits an initial object given by the unit 1, which is $f_{\otimes}(*)$ for $f : \emptyset \longrightarrow *$. We may thus suppose that U is nonempty. Using Construction 5.3.6, given a $\mathcal{T}$-commutative algebra A we get

$$A^{\mathrm{can}} : \underline{\mathbf{F}}_{\mathcal{T},*} \longrightarrow \underline{\mathbf{CAlg}}_{\mathcal{T}}(\mathcal{C})^{\otimes},$$

and we then get a map $f_{\otimes} f^* A \longrightarrow A$ by applying A^{can} to $f_+ : [U_+ \to *] \longrightarrow [*_+ \to *]$ and factoring the resulting map $f^* A \longrightarrow A$ through a cocartesian lift over f_+ in the base. Using the naturality of this procedure in A, we then obtain our candidate for the counit transformation $\epsilon : f_{\otimes} f^* \longrightarrow \mathrm{id}$. To define the unit transformation $\eta : \mathrm{id} \longrightarrow f^* f_\otimes$, consider the pullback square

$$\begin{array}{ccc} U \times U & \xrightarrow{\mathrm{pr}_2} & U \\ \downarrow{\scriptstyle \mathrm{pr}_1} & & \downarrow{\scriptstyle f} \\ U & \xrightarrow{f} & * \end{array}$$

and the associated equivalence $f^* f_\otimes \simeq (\mathrm{pr}_1)_\otimes (\mathrm{pr}_2)^*$. The summand inclusion $\delta : U \longrightarrow U \times U$ yields a natural transformation

$$\epsilon_{\mathrm{pr}_2^*(-)} : \delta_\otimes \simeq \delta_\otimes(\delta^* \mathrm{pr}_2^*) = (\delta_\otimes \delta^* \mathrm{pr}_2^*) \longrightarrow \mathrm{pr}_2^*,$$

which on objects $B \in \underline{\mathbf{CAlg}}_{\mathcal{T}}(\mathcal{C})_U$ may be described as follows: if we write $U \times U \simeq U \coprod U'$ and $g = \mathrm{pr}_2|_{U'}$, then in terms of the decomposition $\underline{\mathbf{CAlg}}_{\mathcal{T}}(\mathcal{C})_{U \times U} \simeq \underline{\mathbf{CAlg}}_{\mathcal{T}}(\mathcal{C})_U \times \underline{\mathbf{CAlg}}_{\mathcal{T}}(\mathcal{C})_{U'}$, we have that

$$\epsilon_{\mathrm{pr}_2^* B} : \delta_\otimes(B) = (B, 1_{U'}) \longrightarrow \mathrm{pr}_2^*(B) = (B, g^* B)$$

is given by the identity on the first factor and the unique map out of the initial object on the second factor. We then let

$$\eta = (\mathrm{pr}_1)_\otimes(\epsilon_{\mathrm{pr}_2^*(-)}) : \mathrm{id} \simeq (\mathrm{pr}_1)_\otimes \delta_\otimes \longrightarrow (\mathrm{pr}_1)_\otimes \mathrm{pr}_2^* \simeq f^* f_\otimes.$$

It remains to verify the triangle identities. Let $U \simeq \coprod_{i=1}^n U_i$ be an orbit decomposition of U, let $\iota_i : U_i \longrightarrow U$ denote the inclusion, and let $f_i = f \circ \iota_i$. Observe that after pullback to U_i, the map f acquires a canonical section, i.e., for all $1 \leq i \leq n$ we have a factorization of the identity map

$$\mathrm{id} : U_i \xrightarrow{(\mathrm{id}, \iota_i)} U_i \times U \xrightarrow{p^i} U_i.$$

where p^i denote the projection. Using $(-)^{\mathrm{can}}$, this furnishes a factorization

$$\mathrm{id} : f_i^* A \longrightarrow (p^i)_\otimes (p^i)^* (f_i^* A) \simeq (p^i)_\otimes (\mathrm{pr}_2)^* f^* A \longrightarrow f_i^* A,$$

where we use the commutative square

$$\begin{array}{ccc} U_i \times U & \xrightarrow{\mathrm{pr}_2} & U \\ \downarrow{\scriptstyle p^i} & & \downarrow{\scriptstyle f} \\ U_i & \xrightarrow{f_i} & * \end{array}$$

for the middle equivalence. To express this in more familiar terms, note that if we write $U_i \times U \simeq U_i \coprod U_i'$ and $q^i = p^i|_{U_i'}$, then we may identify this as

$$f_i^* A \simeq f_i^* A \otimes 1_{U_i} \xrightarrow{\mathrm{id} \otimes 1} f_i^* A \otimes (q^i)_\otimes (q^i)^* A \xrightarrow{\mathrm{id} \otimes \epsilon} f_i^* A \otimes f_i^* A \xrightarrow{\epsilon} f_i^* A,$$

where $\otimes$ denotes the fiberwise tensor product on $\underline{\mathbf{CAlg}}_{\mathcal{T}}(\mathcal{C})_{U_i}$ induced by the fold map $\nabla : U_i \coprod U_i \longrightarrow U_i$.

Now regarding the composition $f^* A \xrightarrow{\eta f^*} f^* f_\otimes f^* A \xrightarrow{f^* \epsilon} f^* A$, by an elementary diagram chase we see that after pullback along ι_i this identifies with the factorization of $f_i^* A$ given above, which validates this half of the triangle identities.

Finally, we consider the composition $f_\otimes B \xrightarrow{f_\otimes \eta} f_\otimes f^* f_\otimes B \xrightarrow{\epsilon f^*} f_\otimes B$. By the $\mathcal{T}$-symmetric monoidality of $(-)^{\mathrm{can}}$, we get a canonical equivalence $f_\otimes(B^{\mathrm{can}}) \simeq (f_\otimes B)^{\mathrm{can}}$ in $\mathbf{CAlg}_{\mathcal{T}}(\underline{\mathbf{CAlg}}_{\mathcal{T}}(\mathcal{C}))$. If we then write $B = (A_1, ..., A_n)$ under the decomposition $\underline{\mathbf{CAlg}}_{\mathcal{T}}(\mathcal{C})_U \simeq \prod_{i=1}^n \underline{\mathbf{CAlg}}_{\mathcal{T}}(\mathcal{C})_{U_i}$, it follows that we obtain an equivalence

$$f_\otimes f^* f_\otimes B \simeq f_\otimes((p^1)_\otimes (p^1)^* A_1, ..., (p^n)_\otimes (p^n)^* A_n)$$

under which $\epsilon_{f_\otimes B} \simeq f_\otimes(\epsilon_{A_1}, ..., \epsilon_{A_n})$ and the composite $\epsilon_{f_\otimes B} \circ f_\otimes \eta_B$ identifies with $f_\otimes$ of the composite defined factorwise by the map $A_i \longrightarrow (p^i)_\otimes (p^i)^* A_i \longrightarrow A_i$ induced from $\mathrm{id} : U_i \xrightarrow{(\mathrm{id}, \iota_i)} U_i \times U \xrightarrow{p^i} U_i$. Since these all compose as identities, we deduce the other half of the triangle identities. □

5.3.8. **Corollary.** *Let $\mathcal{C}^\otimes$ be a $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-category. Then the $\mathcal{T}$-symmetric monoidal structure on $\underline{\mathbf{CAlg}}_{\mathcal{T}}(\mathcal{C})$ of Theorem-Construction 5.3.4 is cocartesian.*

Next, we consider the more general case of an arbitrary $\mathcal{T}$-indexing system $\mathcal{I}$ (Definition 2.4.8).

5.3.9. **Theorem.** *Let $\mathcal{C}^{\otimes}$ be a $\mathcal{I}$-symmetric monoidal $\mathcal{T}$-∞-category. Then for all orbits $V \in \mathcal{T}$, the fiber $\underline{\mathbf{CAlg}}_{\mathcal{I}}(\mathcal{C})_V$ admits finite coproducts, and for all morphisms $f : V \longrightarrow W \in \mathcal{T}$, the restriction functor $f^* : \underline{\mathbf{CAlg}}_{\mathcal{I}}(\mathcal{C})_W \longrightarrow \underline{\mathbf{CAlg}}_{\mathcal{I}}(\mathcal{C})_V$ preserves finite coproducts. Moreover, finite coproducts are computed as tensor products in terms of the symmetric monoidal structures on the fibers $\underline{\mathbf{CAlg}}_{\mathcal{I}}(\mathcal{C})_V$ constructed via Theorem-Construction 5.3.4 applied to the bifunctor*

$$\wedge_{\mathcal{I}} : \mathrm{Com}^{\otimes}_{\mathcal{T}^{\simeq}} \times_{\mathcal{T}^{\mathrm{op}}} \mathrm{Com}^{\otimes}_{\mathcal{I}} \longrightarrow \mathrm{Com}^{\otimes}_{\mathcal{I}}$$

obtained by restriction of $\wedge : \underline{\mathbf{F}}_{\mathcal{T},*} \times_{\mathcal{T}^{\mathrm{op}}} \underline{\mathbf{F}}_{\mathcal{T},*} \longrightarrow \underline{\mathbf{F}}_{\mathcal{T},*}$.

Proof. The proof is exactly analogous to that of Theorem 5.3.7, where in place of Construction 5.3.6 we instead use the composition of the span involving $\wedge_{\mathcal{I}}$ with that involving $\wedge_{\mathcal{T}^{\simeq}}$ to define the $\mathcal{T}^{\simeq}$-symmetric monoidal $\mathcal{T}$-functor

$$\underline{\mathbf{CAlg}}_{\mathcal{I}}(\mathcal{C})^{\otimes} \longrightarrow \underline{\mathbf{CAlg}}_{\mathcal{T}^{\simeq}}(\underline{\mathbf{CAlg}}_{\mathcal{I}}(\mathcal{C}))^{\otimes},$$

and also the identification of Corollary 2.4.15. □

5.3.10. **Corollary.** *Let $\mathcal{C}^{\otimes}$ be a distributive $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-category such that $\mathcal{C}$ is fiberwise presentable, let $\mathcal{I}$ be a $\mathcal{T}$-indexing system, and write $\mathcal{C}^{\otimes}_{\mathcal{I}} = \mathrm{Com}^{\otimes}_{\mathcal{I}} \times_{\underline{\mathbf{F}}_{\mathcal{T},*}} \mathcal{C}^{\otimes}$. Let*

$$\mathrm{U} : \underline{\mathbf{CAlg}}_{\mathcal{T}}(\mathcal{C}) \longrightarrow \underline{\mathbf{CAlg}}_{\mathcal{I}}(\mathcal{C}_{\mathcal{I}})$$

be the forgetful $\mathcal{T}$-functor implemented by restriction along $\mathrm{Com}^{\otimes}_{\mathcal{I}} \subset \underline{\mathbf{F}}_{\mathcal{T},*}$. Then for all $V \in \mathcal{T}$, U_V is a conservative functor of presentable ∞-categories that preserves all small limits and colimits, and is hence comonadic. In particular, $\underline{\mathbf{CAlg}}_{\mathcal{T}}(\mathcal{C})_V$ is comonadic over $\mathbf{CAlg}(\mathcal{C}_V)$.

Proof. To reduce notational clutter, let us replace $\mathcal{T}$ by $\mathcal{T}^{/V}$ so that $V = *$ is a terminal object of $\mathcal{T}$. By Theorem 5.1.4(4), both $\mathbf{CAlg}_{\mathcal{T}}(\mathcal{C})$ and $\mathbf{CAlg}_{\mathcal{I}}(\mathcal{C}_{\mathcal{I}})$ are presentable. Since the forgetful functor to $\mathcal{C}_*$ is conservative for a reduced $\mathcal{T}$-∞-operad, U_* is conservative as well. By Theorem 5.1.3(2), U_* preserves all small limits. By Theorem 5.1.4(2), U_* preserves all sifted colimits. By Theorem 5.3.7 and Theorem 5.3.9, U_* preserves all finite coproducts. It follows that U_* preserves all small colimits and hence admits a right adjoint by the adjoint functor theorem, so we are entitled to ask about the comonadicity of U_*. The conclusion then follows from the Barr–Beck–Lurie Theorem [Lur09, Thm. 4.7.3.5]. □

6. $\mathcal{T}$-symmetric monoidal structure on $\mathcal{T}$-presheaves

Let $\mathcal{C}$ be a $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-category. In this section, we construct a $\mathcal{T}$-symmetric monoidal structure on the $\mathcal{T}$-∞-category of $\mathcal{T}$-presheaves $\underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})$ such that for any $\mathcal{T}$-distributive $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-category $\mathcal{D}$, the universal mapping property

$$\underline{\mathrm{Fun}}^{L}_{\mathcal{T}}(\underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C}), \mathcal{D}) \xrightarrow{\simeq} \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{C}, \mathcal{D})$$

of [Sha21a, Thm. 11.5] refines to an equivalence

$$\underline{\mathrm{Fun}}^{L,\otimes}_{\mathcal{T}}(\underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C}), \mathcal{D}) \xrightarrow{\simeq} \underline{\mathrm{Fun}}^{\otimes}_{\mathcal{T}}(\mathcal{C}, \mathcal{D});$$

cf. Corollary 6.0.12. This result has also been achieved by Hilman as [Hil22a, Thm. 2.3.6].

We first extend our discussion of universal constructions from [Sha21b] by proving the parametrized analogue of [Lur09, Prop. 5.3.6.2].[14] Let $\mathcal{K} = \{\mathcal{K}_U : U \in \mathcal{T}\}$ be a collection of classes $\mathcal{K}_U$ of small $\mathcal{T}^{/U}$-∞-categories such that for each morphism $f : U \longrightarrow V$ in $\mathcal{T}$, $f^*(\mathcal{K}_V) \subset \mathcal{K}_U$; we call such a collection *closed*. For each $V \in \mathcal{T}$, let $\mathcal{K}|_V = \{\mathcal{K}_U : [f : U \to V] \in \mathcal{T}\}$. Recall the following definition from [Sha21b, Def. 2.8]

6.0.1. **Definition.** Let $\mathcal{C}$ be a $\mathcal{T}$-∞-category. We say that $\mathcal{C}$ *strongly admits* $\mathcal{K}$-indexed $\mathcal{T}$-colimits if for all $U \in \mathcal{T}$, $\mathcal{C}_{\underline{U}}$ admits $\mathcal{K}_U$-indexed $\mathcal{T}^{/U}$-colimits. Likewise, for any $V \in \mathcal{T}$, we may refer to $\mathcal{C}_{\underline{V}}$ strongly admitting $\mathcal{K}|_V$-indexed $\mathcal{T}^{/V}$-colimits.

Given a $\mathcal{T}$-functor $F : \mathcal{C} \longrightarrow \mathcal{D}$, we say that F *strongly preserves* $\mathcal{K}$-indexed $\mathcal{T}$-colimits if for all $U \in \mathcal{T}$, the $\mathcal{T}^{/U}$-functor $F_{\underline{U}} : \mathcal{C}_{\underline{U}} \longrightarrow \mathcal{D}_{\underline{U}}$ preserves all $\mathcal{K}_U$-indexed $\mathcal{T}^{/U}$-colimits. Likewise, for any $V \in \mathcal{T}$, we may refer to $F_{\underline{V}}$ strongly preserving $\mathcal{K}|_V$-indexed $\mathcal{T}^{/V}$-colimits. We then let

$$\underline{\mathrm{Fun}}^{\mathcal{K}}_{\mathcal{T}}(\mathcal{C}, \mathcal{D}) \subset \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{C}, \mathcal{D})$$

[14] For this, we need not suppose that $\mathcal{T}$ is atomic.

be the full $\mathcal{T}$-subcategory spanned in each fiber over $V \in \mathcal{T}$ by those $\mathcal{T}^{/V}$-functors that strongly preserve $\mathcal{K}|_V$-indexed $\mathcal{T}^{/V}$-colimits. Note that the global sections $\mathrm{Fun}^{\mathcal{K}}_{\mathcal{T}}(\mathcal{C},\mathcal{D})$ of $\underline{\mathrm{Fun}}^{\mathcal{K}}_{\mathcal{T}}(\mathcal{C},\mathcal{D})$ is then the full subcategory of $\mathrm{Fun}_{\mathcal{T}}(\mathcal{C},\mathcal{D})$ spanned by those $\mathcal{T}$-functors that strongly preserve $\mathcal{K}$-indexed $\mathcal{T}$-colimits.

Suppose given a collection $\mathcal{R} = \{\mathcal{R}_U : U \in \mathcal{T}\}$ of classes $\mathcal{R}_U = \{\overline{p_\alpha} : \mathcal{K}_\alpha^{\triangleright} \longrightarrow \mathcal{C}_{\underline{U}}\}$ of $\mathcal{T}^{/U}$-diagrams in $\mathcal{C}_{\underline{U}}$ (which are not necessarily $\mathcal{T}^{/U}$-colimit diagrams), such that for each morphism $f : U \longrightarrow V$ in $\mathcal{T}$, $f^*(\mathcal{R}_V) \subset \mathcal{R}_U$. Then a $\mathcal{T}$-functor $F : \mathcal{C} \longrightarrow \mathcal{D}$ *strongly preserves* $\mathcal{R}$-indexed $\mathcal{T}$-colimits if for all $U \in \mathcal{T}$, $F_{\underline{U}} : \mathcal{C}_{\underline{U}} \longrightarrow \mathcal{D}_{\underline{U}}$ sends each $\overline{p_\alpha}$ to $\mathcal{T}^{/U}$-colimit diagram in $\mathcal{D}_{\underline{U}}$. Likewise, for any $V \in \mathcal{T}$ we have the same notion for $F_{\underline{V}}$ with respect to $\mathcal{R}|_V$. We then let

$$\underline{\mathrm{Fun}}^{\mathcal{R}}_{\mathcal{T}}(\mathcal{C},\mathcal{D}) \subset \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{C},\mathcal{D})$$

be defined as before.

6.0.2. **Proposition.** *Let $\mathcal{C}$ be a $\mathcal{T}$-∞-category and let $\mathcal{R}$ be as in Definition 6.0.1, such that each $\mathcal{K}_\alpha$ lies in $\mathcal{K}_U$.*

Then there exists a $\mathcal{T}$-∞-category $\underline{\mathbf{P}}^{\mathcal{K}}_{\mathcal{R}}(\mathcal{C})$ and a $\mathcal{T}$-functor $j : \mathcal{C} \longrightarrow \underline{\mathbf{P}}^{\mathcal{K}}_{\mathcal{R}}(\mathcal{C})$ such that:

(1) $\underline{\mathbf{P}}^{\mathcal{K}}_{\mathcal{R}}(\mathcal{C})$ strongly admits $\mathcal{K}$-indexed $\mathcal{T}$-colimits.
(2) For all $\mathcal{T}$-∞-categories $\mathcal{D}$ such that $\mathcal{D}$ strongly admits $\mathcal{K}$-indexed $\mathcal{T}$-colimits, precomposition with j induces an equivalence of $\mathcal{T}$-∞-categories

$$j^* : \underline{\mathrm{Fun}}^{\mathcal{K}}_{\mathcal{T}}(\underline{\mathbf{P}}^{\mathcal{K}}_{\mathcal{R}}(\mathcal{C}),\mathcal{D}) \xrightarrow{\simeq} \underline{\mathrm{Fun}}^{\mathcal{R}}_{\mathcal{T}}(\mathcal{C},\mathcal{D})$$

which upon passage to global sections yields an equivalence of ∞-categories

$$j^* : \mathrm{Fun}^{\mathcal{K}}_{\mathcal{T}}(\underline{\mathbf{P}}^{\mathcal{K}}_{\mathcal{R}}(\mathcal{C}),\mathcal{D}) \xrightarrow{\simeq} \mathrm{Fun}^{\mathcal{R}}_{\mathcal{T}}(\mathcal{C},\mathcal{D}).$$

(3) Suppose that all $\mathcal{T}^{/U}$-functors $\overline{p_\alpha} : \mathcal{K}_\alpha^{\triangleright} \longrightarrow \mathcal{C}_{\underline{U}}$ in $\mathcal{R}_U$ are $\mathcal{T}^{/U}$-colimit diagrams. Then j is fully faithful.

Proof. The proof is essentially identical to that of [Lur09, Prop. 5.3.6.2]; we spell out a few details for the reader's benefit. After enlarging universes, we may suppose $\mathcal{C}$ is small.[15] Let $j_0 : \mathcal{C} \longrightarrow \underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})$ be the $\mathcal{T}$-Yoneda embedding. For every $\overline{p_\alpha} \in \mathcal{R}_U$, let $p_\alpha = \overline{p_\alpha}|_{\mathcal{K}_\alpha}$, let $Y_\alpha \in \underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})_U$ be the image of the cone point (in the fiber over U) under $\overline{p_\alpha}$, let $X_\alpha \in \underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})_U$ be a $\mathcal{T}^{/U}$-colimit for $(j_0)_{\underline{U}} \circ p_\alpha : \mathcal{K}_\alpha \longrightarrow \underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})_{\underline{U}}$, let $s_\alpha : X_\alpha \longrightarrow j_0(Y_\alpha)$ be the induced map, and let $S_U = \{s_\alpha\}$.

Note that for all morphisms $f : U \longrightarrow V$ in $\mathcal{T}$, $f^* S_V \subset S_U$ by our closure hypothesis on $\mathcal{R}$. Thus, we may form the full $\mathcal{T}$-subcategory $S^{-1}\underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C}) \subset \underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})$ given on each fiber over $U \in \mathcal{T}$ by the full subcategory of S_U-local objects of $\mathbf{P}_{\mathcal{T}^{/U}}(\mathcal{C}_{\underline{U}}) = \underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})_U$. We then have a $\mathcal{T}$-left adjoint $L : \underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C}) \longrightarrow S^{-1}\underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})$ given fiberwise by the usual localization. Finally, we define $\underline{\mathbf{P}}^{\mathcal{K}}_{\mathcal{R}}(\mathcal{C})$ to be the smallest full $\mathcal{T}$-subcategory of $S^{-1}\underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})$ which contains the essential image of $L \circ j_0$ and such that for each $U \in \mathcal{T}$, $\underline{\mathbf{P}}^{\mathcal{K}}_{\mathcal{R}}(\mathcal{C})$ is closed under $\mathcal{K}_U$-indexed colimits, and we let $j = L \circ j_0$ be the induced map.

Given this construction, the verification of properties (1)–(3) proceeds exactly as in the proof of [Lur09, Prop. 5.3.6.2] (with parametrized analogues of non-parametrized statements involving colimits, left Kan extensions, etc. substituted as appropriate). □

6.0.3. **Remark.** If $\mathcal{K} = \mathcal{A}ll$ then we may also write $\underline{\mathbf{P}}^{\mathcal{K}}_{\mathcal{R}}(\mathcal{C})$ as $\underline{\mathbf{P}}_{\mathcal{R}}(\mathcal{C})$.

Now let $\underline{\mathbf{Cat}}^{\otimes}_{\mathcal{T}} \longrightarrow \underline{\mathbf{F}}_{\mathcal{T},*}$ be the $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-category given by the $\mathcal{T}$-cartesian $\mathcal{T}$-symmetric monoidal structure on $\underline{\mathbf{Cat}}_{\mathcal{T}}$ (Example 2.4.1). Objects of $\underline{\mathbf{Cat}}^{\otimes}_{\mathcal{T}}$ are then given by tuples

$$([f : U \to V] \in \underline{\mathbf{F}}_{\mathcal{T},*},\ \mathcal{C}_1 \in \mathbf{Cat}_{\mathcal{T}^{/U_1}},\ \dots,\ \mathcal{C}_n \in \mathbf{Cat}_{\mathcal{T}^{/U_n}})$$

where $U \simeq U_1 \sqcup \dots \sqcup U_n$ is an orbit decomposition.

To describe morphisms in $\underline{\mathbf{Cat}}^{\otimes}_{\mathcal{T}}$, consider a morphism

$$\begin{array}{ccccc} U & \longleftarrow & Z & \xrightarrow{m} & X \\ \downarrow{\scriptstyle f} & & \downarrow & & \downarrow{\scriptstyle g} \\ V & \longleftarrow & Y & \xrightarrow{=} & Y \end{array}$$

[15] Since we suppose $\mathcal{T}$ is small, a $\mathcal{T}$-∞-category $\mathcal{C}$ is small if and only if it is fiberwise small.

in $\underline{\mathbf{F}}_{\mathcal{T},*}$, let $U \simeq \coprod_{i=1}^n U_i$, $X \simeq \coprod_{j=1}^m X_j$ be orbit decompositions, and let $m_j : Z_j \simeq X_j \times_Y Z \longrightarrow X_j$ be the restriction over the summand X_j. Let $\{\mathcal{C}_i \in \mathbf{Cat}_{\mathcal{T}/U_i}\}$ and $\{\mathcal{D}_j \in \mathbf{Cat}_{\mathcal{T}/X_j}\}$. Let $\mathcal{C} = \coprod_{i=1}^n \mathcal{C}_i$ denote the given $\mathcal{T}^{/U}$-∞-category and let $\mathrm{pr}^*\mathcal{C}$ denote the pullback of $\mathcal{C}$ to a $\mathcal{T}^{/U\times_V Y}$-$\infty$-category along the projection $U \times_V Y \longrightarrow U$. By definition, the map $Z \longrightarrow U \times_V Y$ is a summand inclusion; let $\mathcal{C}'$ denote the corresponding summand of $\mathcal{C}$ regarded as a $\mathcal{T}^{/Z}$-∞-category, and also let $\mathcal{C}'_j$ denote the $\mathcal{T}^{/Z_j}$-∞-category given by the further summand of $\mathcal{C}'$. Then a morphism

$$(f, \{\mathcal{C}_i\}) \longrightarrow (g, \{\mathcal{D}_j\})$$

is given by a collection of $\mathcal{T}^{/X_j}$-functors $F_j : (m_j)_*(\mathcal{C}'_j) \longrightarrow \mathcal{D}_j$, or written more concisely, a $\mathcal{T}^{/X}$-functor $F : m_*(\mathcal{C}') \longrightarrow \mathcal{D}$.

6.0.4. **Definition.** Let $\mathcal{M} \subset \underline{\mathbf{Cat}}^{\otimes}_{\mathcal{T}} \times \Delta^1$ be the subcategory defined as follows:

- $\mathcal{M}_0 = \underline{\mathbf{Cat}}^{\otimes}_{\mathcal{T}}$.
- An object $([f : U \to V], \mathcal{C}_1 \in \mathbf{Cat}_{\mathcal{T}/U_1}, ..., \mathcal{C}_n \in \mathbf{Cat}_{\mathcal{T}/U_n})$ belongs to $\underline{\mathbf{Cat}}^{\otimes}_{\mathcal{T}} \times \{1\}$ if and only if each $\mathcal{C}_i$ strongly admits $\mathcal{T}^{/U_i}$-colimits.
- All morphisms $(f, \{\mathcal{C}_i\}, 0) \longrightarrow (g, \{\mathcal{D}_j\}, 1)$ belong to $\mathcal{M}$.
- A morphism $(f, \{\mathcal{C}_i\}, 1) \longrightarrow (g, \{\mathcal{D}_j\}, 1)$ belongs to $\mathcal{M}$ if and only if each F_j is $\mathcal{T}^{/X_i}$-distributive.

Let $p : \mathcal{M} \longrightarrow \underline{\mathbf{F}}_{\mathcal{T},*} \times \Delta^1$ denote the composite of the inclusion and the structure map.

For the following, we have implicitly extended the notion of (closed) collection $\mathcal{K} = \{\mathcal{K}_U\}$ to be indexed over all finite $\mathcal{T}$-sets U.

6.0.5. **Notation.** Let $f : U \longrightarrow V$ be a morphism in $\mathbf{F}_{\mathcal{T}}$ and let $\mathcal{C}$ be a $\mathcal{T}^{/U}$-∞-category. Let $\mathcal{R} = \{\mathcal{R}_\alpha : [U' \xrightarrow{\alpha} U] \in \mathbf{F}_{\mathcal{T}}\}$ be a closed collection of diagrams in $\mathcal{C}$, $\mathcal{R}_\alpha = \{\overline{p_\alpha} : \mathcal{K}_\alpha^{\triangleright} \longrightarrow \mathcal{C}_{\underline{U'}}\}$. We let $f_*\mathcal{R}$ denote the closed collection of diagrams in $f_*\mathcal{C}$ specified at each morphism $\gamma : V' \longrightarrow V$ as follows:

(∗) Let $U' = U \times_V V'$ and let $f' : U' \longrightarrow V'$ be the pullback of f. For every $\mathcal{T}^{/U'}$-diagram $\overline{p_\alpha} : \mathcal{K}_\alpha^{\triangleright} \longrightarrow \mathcal{C}_{\underline{U'}}$ in $\mathcal{R}_{U'}$, we may form the $\mathcal{T}^{/V'}$ diagram

$$f'_*(\mathcal{K}_\alpha)^{\triangleright} \xrightarrow{\mathrm{can}} f'_*(\mathcal{K}_\alpha^{\triangleright}) \xrightarrow{f'_*(\overline{p_\alpha})} f'_*(\mathcal{C}_{\underline{U'}}) \simeq (f_*\mathcal{C})_{\underline{V'}}.$$

Let $(f_*\mathcal{C})_\gamma$ be the set of these diagrams.

6.0.6. **Notation.** Given a finite $\mathcal{T}$-set U with orbit decomposition $U \simeq \coprod_{i=1}^n U_i$, let $\underline{\mathbf{P}}_{\mathcal{T}/U}(-)$ be given by the coproduct of the $\underline{\mathbf{P}}_{\mathcal{T}/U_i}(-)$.

6.0.7. **Lemma.** *Let $f : U \longrightarrow V$ be a morphism of finite $\mathcal{T}$-sets and let $\mathcal{C}$ be a $\mathcal{T}^{/U}$-∞-category. Consider the $\mathcal{T}^{/V}$-functor*

$$\phi : f_*\underline{\mathbf{P}}_{\mathcal{T}/U}(\mathcal{C}) \longrightarrow \underline{\mathbf{P}}_{\mathcal{T}/V}(f_*\mathcal{C})$$

given by the composite of the $\mathcal{T}^{/U}$-Yoneda embedding (for $f_*\underline{\mathbf{P}}_{\mathcal{T}/U}(\mathcal{C})$) and restriction along f_* of the $\mathcal{T}^{/V}$-Yoneda embedding (for $\mathcal{C}$). Then ϕ is $\mathcal{T}^{/V}$-distributive.

Proof. Suppose $p : \mathcal{K} \longrightarrow \underline{\mathbf{P}}_{\mathcal{T}/U}(\mathcal{C})$ is a $\mathcal{T}^{/U}$-diagram. We need to show that the $\mathcal{T}^{/V}$-colimit of the composite

$$f_*\mathcal{K} \xrightarrow{f_*(p)} f_*\underline{\mathbf{P}}_{\mathcal{T}/U}(\mathcal{C}) \xrightarrow{\phi} \underline{\mathbf{P}}_{\mathcal{T}/V}(f_*\mathcal{C})$$

evaluates to $f_*(\mathrm{colim}^{\mathcal{T}^{/U}} p)$. It suffices to check this after evaluation at all objects of $f_*\mathcal{C}$, and without loss of generality it suffices to consider $x \in (f_*\mathcal{C})_V \simeq \mathcal{C}_U$ (by the usual base-change argument). A diagram chase then shows that the composite

$$f_*\underline{\mathbf{P}}_{\mathcal{T}/U}(\mathcal{C}) \xrightarrow{\phi} \underline{\mathbf{P}}_{\mathcal{T}/V}(f_*\mathcal{C}) \xrightarrow{\mathrm{ev}_x} \underline{\mathbf{Spc}}_{\mathcal{T}/V}$$

identifies with the composite

$$f_*\underline{\mathbf{P}}_{\mathcal{T}/U}(\mathcal{C}) \xrightarrow{f_*\mathrm{ev}_x} f_*\underline{\mathbf{Spc}}_{\mathcal{T}/U} = f_*f^*\underline{\mathbf{Spc}}_{\mathcal{T}/V} \xrightarrow{m} \underline{\mathbf{Spc}}_{\mathcal{T}/V}$$

where m is the multiplication given by the $\mathcal{T}$-distributive $\mathcal{T}$-cartesian $\mathcal{T}$-symmetric monoidal structure on $\underline{\mathbf{Spc}}_{\mathcal{T}}$. Thus, m is $\mathcal{T}^{/V}$-distributive, which implies that $\mathrm{ev}_x\phi$ is distributive. □

6.0.8. **Lemma.** *Let $f : U \longrightarrow V$ be a morphism of finite $\mathcal{T}$-sets, let $\mathcal{C}$ be a $\mathcal{T}^{/U}$-∞-category, and let $\mathcal{D}$ be a $\mathcal{T}^{/U}$-cocomplete $\mathcal{T}^{/U}$-∞-category. Then a $\mathcal{T}^{/V}$-functor $F : f_* \underline{\mathbf{P}}_{\mathcal{T}^{/U}}(\mathcal{C}) \longrightarrow \mathcal{D}$ is $\mathcal{T}^{/V}$-distributive if and only if it is the $\mathcal{T}^{/V}$-left Kan extension of its restriction along $f_*(j) : f_*\mathcal{C} \subset f_*\underline{\mathbf{P}}_{\mathcal{T}^{/U}}(\mathcal{C})$.*

Proof. For the 'if' direction, it suffices to consider the universal example given by the $\mathcal{T}^{/V}$-functor ϕ of Lemma 6.0.7, which we showed to be $\mathcal{T}^{/V}$-distributive.[16] For the 'only if' direction, let $F' = (f_*j)_!(f_*j)^*F$ and consider the comparison map $\theta : F' \Rightarrow F$. Without loss of generality, it suffices to show that for all $x \in (f_*\underline{\mathbf{P}}_{\mathcal{T}^{/U}}(\mathcal{C}))_V \simeq (\underline{\mathbf{P}}_{\mathcal{T}^{/U}}(\mathcal{C}))_U$, θ_x is an equivalence. On the one hand, by the pointwise formula for $\mathcal{T}^{/V}$-left Kan extensions, we have that $F'(x)$ is given by the $\mathcal{T}^{/V}$-colimit of $p : (f_*\mathcal{C})^{/\underline{x}} \longrightarrow f_*\mathcal{C} \longrightarrow \mathcal{D}$. On the other hand, since $f_* : \mathbf{Cat}_{\mathcal{T}^{/U}} \longrightarrow \mathbf{Cat}_{\mathcal{T}^{/V}}$ preserves cotensors and limits, we have a natural equivalence $(f_*\mathcal{C})^{/\underline{x}} \simeq f_*(\mathcal{C}^{/\underline{x}})$ such that $[(f_*\mathcal{C})^{/\underline{x}} \longrightarrow f_*\mathcal{C}] \simeq [f_*(\mathcal{C}^{/\underline{x}} \longrightarrow \mathcal{C})]$, and using that F is $\mathcal{T}^{/V}$-distributive, we get that $F(x)$ is also given by the $\mathcal{T}^{/V}$-colimit of p. The naturality of all operations considered shows further that θ_x implements this equivalence. □

In the following corollary, we disambiguate our terminology for distributive functors by referring to the morphism of finite $\mathcal{T}$-sets and not just the target.

6.0.9. **Corollary.** *Let $U \xrightarrow{f} V \xrightarrow{g} W$ be a composite of morphisms of finite $\mathcal{T}$-sets, let $\mathcal{C}$ be a $\mathcal{T}^{/U}$-cocomplete $\mathcal{T}^{/U}$-∞-category, and let $\mathcal{D}$ be a $\mathcal{T}^{/W}$-cocomplete $\mathcal{T}^{/W}$-∞-category. Consider the composite $\mathcal{T}^{/W}$-functor*

$$j : g_*f_*\mathcal{C} \xrightarrow{j_0} g_*\underline{\mathbf{P}}_{\mathcal{T}^{/V}}(f_*\mathcal{C}) \longrightarrow g_*\underline{\mathbf{P}}_{f_*\mathcal{A}ll}(f_*\mathcal{C})$$

Then a $\mathcal{T}^{/W}$-functor $F : g_*\underline{\mathbf{P}}_{f_*\mathcal{A}ll}(f_*\mathcal{C}) \longrightarrow \mathcal{D}$ is g-distributive if and only if j^*F is gf-distributive. Consequently, we have an equivalence

$$\underline{\mathbf{P}}_{(gf)_*\mathcal{A}ll}((gf)_*\mathcal{C}) \simeq \underline{\mathbf{P}}_{g_*\mathcal{A}ll}(g_*\underline{\mathbf{P}}_{f_*\mathcal{A}ll}(f_*\mathcal{C})).$$

Proof. The first claim follows immediately by restricting the equivalence of Lemma 6.0.8, noting that by definition $g_*\underline{\mathbf{P}}_{f_*\mathcal{A}ll}(f_*\mathcal{C})$ is a localization of $g_*\underline{\mathbf{P}}_{\mathcal{T}^{/V}}(f_*\mathcal{C})$ at the relevant class of morphisms. The equivalence then follows by universal property. □

6.0.10. **Proposition.** *The map p is a cocartesian fibration.*

Proof. We adapt the proof of [Lur17, Prop. 4.8.1.3] to the parametrized context. We first show that p is a locally cocartesian fibration. This is clear if we restrict to the fiber over 0. For the other cases, first suppose $(f : U \to V, \{\mathcal{C}_i\}) \in \mathcal{M}_0$ and let $(f, 0) \longrightarrow (g, 1)$ be a morphism in $\underline{\mathbf{F}}_{\mathcal{T},*} \times \Delta^1$, with notation as above. Let $\mathcal{D}_j = \underline{\mathbf{P}}_{\mathcal{T}^{/X_j}}((m_j)_*(\mathcal{C}'_j))$ and take F_j to be the identity. We then have a morphism $(f, \{\mathcal{C}_i\}, 0) \longrightarrow (g, \{\mathcal{D}_j\}, 1)$ which is a locally cocartesian edge by the universal property of the $\mathcal{T}^{/X_j}$-presheaves.

Next, suppose $(f : U \to V, \{\mathcal{C}_i\}) \in \mathcal{M}_1$ and let $(f, 1) \longrightarrow (g, 1)$ be a morphism in $\underline{\mathbf{F}}_{\mathcal{T},*} \times \Delta^1$. Let $\mathcal{C}'$ be the $\mathcal{T}^{/Z}$-∞-category as above. Let $\mathcal{R}$ be the closed collection of parametrized colimit diagrams in $\mathcal{C}'$, i.e., for each morphism $\alpha : Z' \longrightarrow Z$ in $\mathbf{F}_{\mathcal{T}}$, $\mathcal{R}_\alpha$ is the collection of $\mathcal{T}^{/Z'}$-colimit diagrams in $\mathcal{C}'_{\underline{Z'}}$. We let $\mathcal{D} = \underline{\mathbf{P}}^{\mathcal{A}ll}_{m_*\mathcal{R}}(m_*\mathcal{C}')$ and $F = j : m_*\mathcal{C}' \longrightarrow \mathcal{D}$ be the $\mathcal{T}^{/X}$-functor as in Proposition 6.0.2. We then have that the morphism $j : (f, \mathcal{C}, 1) \longrightarrow (g, \mathcal{D}, 1)$ lies in $\mathcal{M}$ by definition. Moreover, it is a locally cocartesian edge in view of the universal property supplied by Proposition 6.0.2.

To then see that p is a cocartesian fibration, we need to see that the composite of locally cocartesian edges is again locally cocartesian. We already know the restriction over 0 is a cocartesian fibration. If the first edge lies over $[0 \to 1]$, we may apply the parametrized analogue of [Lur09, Prop. 5.3.6.11]; since this step is straightforward we leave the details to the reader. If both edges lie over 1, then without loss of generality we may suppose both edges are fiberwise active as edges over $\underline{\mathbf{F}}_{\mathcal{T},*}$, in which case the claim follows from the transitivity property established in Corollary 6.0.9. □

Let p_0 and p_1 denote the two fibers of p over $0, 1 \in \Delta^1$.

6.0.11. **Corollary.** *The maps p_0 and p_1 exhibit $\mathcal{M}_0$ and $\mathcal{M}_1$ as $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-categories.*

[16] cf. https://math.stackexchange.com/questions/4094599/when-left-kan-extension-preserve-colimits for a description of this standard reduction, which also works in the parametrized context.

Proof. We already have that the map p_0 is the structure map of $\underline{\mathbf{Cat}}_{\mathcal{T}}^{\otimes}$. As for p_1, since it is a cocartesian fibration it remains to verify the parametrized Segal condition. But in the definition of $\mathcal{M}$, all the inert morphisms in $\underline{\mathbf{Cat}}_{\mathcal{T}}^{\otimes}$ continue to lie in $\mathcal{M}$, so we see that $\mathcal{M}_1$ inherits the parametrized Segal condition from $\underline{\mathbf{Cat}}_{\mathcal{T}}^{\otimes}$. □

Now write $(\underline{\mathbf{Cat}}_{\mathcal{T}}^{L})^{\otimes} = \mathcal{M}_1$. The cocartesian fibration p classifies the $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-functor

$$\underline{\mathbf{P}}_{\mathcal{T}/-}^{\otimes} : \underline{\mathbf{Cat}}_{\mathcal{T}}^{\otimes} \longrightarrow (\underline{\mathbf{Cat}}_{\mathcal{T}}^{L})^{\otimes}$$

whose underlying $\mathcal{T}$-functor is given by the usual $\mathcal{T}$-presheaf construction $\underline{\mathbf{P}}_{\mathcal{T}/-}$. Since $\underline{\mathbf{P}}_{\mathcal{T}/-}$ admits a right $\mathcal{T}$-adjoint given by the forgetful $\mathcal{T}$-functor U, U canonically inherits a lax $\mathcal{T}$-symmetric monoidal structure. Passing to $\mathcal{T}$-commutative algebra objects and considering the unit of the adjunction, we obtain:

6.0.12. **Corollary.** *Let $\mathcal{C}$ be a $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-category. Then $\underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})$ and the $\mathcal{T}$-Yoneda embedding $j : \mathcal{C} \longrightarrow \underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})$ inherit a $\mathcal{T}$-symmetric monoidal structure such that:*

(1) $\underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})$ is $\mathcal{T}$-distributive.
(2) For every $\mathcal{T}$-distributive $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-category $\mathcal{D}$, restriction along j yields an equivalence

$$\underline{\mathrm{Fun}}_{\mathcal{T}}^{L,\otimes}(\underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C}), \mathcal{D}) \xrightarrow{\simeq} \underline{\mathrm{Fun}}_{\mathcal{T}}^{\otimes}(\mathcal{C}, \mathcal{D}).$$

6.0.13. **Remark.** Let $\mathcal{C}$ be a $\mathcal{T}$-symmetric monoidal $\mathcal{T}$-∞-category. Consider the $\mathcal{T}$-distributive $\mathcal{T}$-symmetric monoidal structure on $\underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C}) = \underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{C}^{\mathrm{vop}}, \underline{\mathbf{Spc}}_{\mathcal{T}})$ given by $\mathcal{T}$-Day convolution (Theorem 3.2.6), where we have the $\mathcal{T}$-symmetric monoidal structure on $\mathcal{C}^{\mathrm{vop}}$ induced by the opposite automorphism on **Cat** under the equivalence of Theorem 2.3.9 and the $\mathcal{T}$-cartesian $\mathcal{T}$-symmetric monoidal structure on $\underline{\mathbf{Spc}}_{\mathcal{T}}$. Then one may show directly that the full $\mathcal{T}$-subcategory $\mathcal{C} \subset \underline{\mathbf{P}}_{\mathcal{T}}(\mathcal{C})$ is closed under this $\mathcal{T}$-symmetric monoidal structure. Using Corollary 6.0.12(2), it then follows that the $\mathcal{T}$-Day convolution $\mathcal{T}$-symmetric monoidal structure agrees with that defined above.

On normed $\mathbb{E}_\infty$-rings in genuine equivariant C_p-spectra

Lucy Yang

August 30, 2023

Abstract

Genuine equivariant homotopy theory is equipped with a multitude of coherently commutative multiplication structures generalizing the classical notion of an $\mathbb{E}_\infty$-algebra. In this paper we study the C_p-$\mathbb{E}_\infty$-algebras of Nardin–Shah with respect to a cyclic group C_p of prime power order. We show that many of the higher coherences inherent to the definition of parametrized algebras collapse; in particular, they may be described more simply and conceptually in terms of ordinary $\mathbb{E}_\infty$-algebras as a diagram category which we call *normed algebras*. Our main result provides a relatively straightforward criterion for identifying C_p-$\mathbb{E}_\infty$-algebra structures. We visit some applications of our result to real motivic invariants.

Contents

1 Introduction

1.1 Motivation

Algebraic invariants such as integral cohomology $H^*(-;\mathbb{Z})$ detect information about spaces; identifying and applying such tools form the basic premise of algebraic topology. Moreover, considering more structured algebraic objects leads to more refined invariants: Cochains with integral coefficients $X \mapsto C^*(X;\mathbb{Z})$ considered as a functor from spaces to $\mathbb{E}_\infty$-$\mathbb{Z}$-algebras is *better* at detecting information about spaces than integral cohomology. For instance, $C^*(X;\mathbb{Z})$ inherits power operations as a consequence of its $\mathbb{E}_\infty$-structure, and two (non-equivalent) spaces X and Y may have isomorphic cohomology rings but different power operations. In this way, we see that the study of structured multiplications and their operations is foundational to homotopy theory.

In parallel, the study of structured multiplications is essential to the study of genuine equivariant homotopy types. Our line of inquiry naturally leads to algebraic structures whose operations are inherently genuine equivariant. To motivate the particular equivariant multiplicative structure we will focus on, recall that an ordinary $\mathbb{E}_\infty$-algebra in spectra may be modeled by a functor satisfying certain conditions defined on the category of finite pointed sets [Seg74]. In particular, the smash product $A^{\otimes \ell}$ parametrizes formal sums of ℓ-tuples in A, and said functor takes the collapse map $\langle 2 \rangle \to \langle 1 \rangle$ to a morphism $A^{\otimes 2} \to A$. In particular, $\mathbb{E}_\infty$-algebra structures are governed by the category of finite pointed sets.

In genuine equivariant homotopy theory with respect to the finite cyclic group C_p of order a prime p, the role of finite sets is supplanted by *finite pointed sets with C_p-action* [HH14, §4; HH16, §3.3]. The Hill–Hopkins–Ravenel norm $N_e^{C_p} A =: A^{\otimes C_p}$ parametrizes $|C_p|$-tuples in A indexed by a free C_p-set. In [BH15], Blumberg and Hill introduced a genuine equivariant operads encoding multiplications indexed by G-sets; the algebras they give rise to are called N_∞-algebras. In [NS22, Definition 2.2.2], Nardin and Shah defined an ∞-categorical analogue of the N_∞-algebras of Blumberg–Hill[1]; we shall refer to the latter as C_p-$\mathbb{E}_\infty$-algebras (Definition 2.32, Example 2.33). Their structure of operations is governed by the category of finite pointed C_p-sets $\mathrm{Fin}_{C_p,*}$.

Unravelling definitions, a C_p-$\mathbb{E}_\infty$-algebra is the data of

(1) An underlying C_p-genuine equivariant spectrum R.

(2) For each morphism of finite C_p-sets $S \to T$, a morphism of C_p-spectra $N_e^S R \to N_e^T R$. In particular, the collapse map $C_p \twoheadrightarrow C_p/C_p$ indexes a morphism of $\mathbb{E}_\infty$ rings $n_R \colon N_e^{C_p} R \to R$ called the *norm*.

(3) higher coherences...

To exhibit a C_p-$\mathbb{E}_\infty$-algebra structure on a genuine C_p-spectrum R is no small task. In the literature, one often resorts to simplifying assumptions such as requiring R to be Borel, e.g. [Hil22, Proposition 3.3.6]. We set out to provide a relatively straightforward criterion for identifying C_p-$\mathbb{E}_\infty$-algebra structures.

When $p = 2$, by [QS22, Definition 5.2] the category of C_2-$\mathbb{E}_\infty$-algebras is the natural domain of definition for real (i.e. C_2-equivariant) topological Hochschild homology and other real motivic invariants. This work grew out of the author's interest in real motivic invariants and will be used in upcoming work on a real version of the Hochschild–Kostant–Rosenberg theorem.

[1] These notions are expected to agree.

1.2 Main result

To motivate our main result, note that any morphism of C_p-sets $S \to C_p/C_p$ can be expressed as the composite of 'collapse the free C_p-orbits' followed by a (non-equivariant) map of finite sets. Thus a C_p-$\mathbb{E}_\infty$ algebra, regarded as functor defined on C_p-sets, determines two pieces of data: its restriction to sets on which C_p acts trivially, and its value on collapse maps. The former specifies an $\mathbb{E}_\infty$-algebra structure, while the latter specifies a norm map n. To assert that these data are *enough* to specify a C_p-$\mathbb{E}_\infty$-algebra structure means that any higher coherence conditions on the norm map n collapse. We might hope that this is indeed the case, since the category $\mathrm{Fin}_{C_p,*}$ is *freely* generated by the C_p-set C_p/C_p.

Let $A \in \mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{BC_p})$ be an $\mathbb{E}_\infty$-algebra with naïve C_p-action and $\sigma \in C_p$ a generator.

Observation 1.1 (Observation 3.7)**.** Write $A^{\otimes^\Delta p}$ for the object in $\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{BC_p})$ with the *diagonal* action, i.e. such that σ acts by $\sigma(a_1 \otimes \cdots \otimes a_p) = \sigma(a_p) \otimes \sigma(a_1) \otimes \cdots \otimes \sigma(a_{p-1})$. Write $A^{\otimes^\tau p}$ for the object in $\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{BC_p})$ with the *transposition* action, i.e. such that σ acts by $\sigma(a_1 \otimes \cdots \otimes a_p) = a_p \otimes a_1 \otimes \cdots \otimes a_{p-1}$. Then the endomorphism $\mathrm{id}_A \otimes \sigma \otimes \cdots \otimes \sigma^{p-1}$ of $A^{\otimes p} \in \mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp})$ promotes to an equivalence $A^{\otimes^\Delta p} \to A^{\otimes^\tau p}$ in $\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp})^{BC_p}$–in particular it is C_p-equivariant.

Definition 1.2 (Definition 3.11)**.** Write $\mathcal{O}_{C_p}$ for the category of finite sets with transitive C_p-action, and let $\sigma \in C_p$ be a generator. A *normed $\mathbb{E}_\infty$-algebra* in C_p-spectra is the data of an $\mathbb{E}_\infty$-algebra A in Sp^{C_p}, a morphism of $\mathbb{E}_\infty$-rings $n_A \colon N^{C_p}(A^e_{hC_p}) \to A$, and a homotopy making the following diagram $\mathcal{O}_{C_p} \to \mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp})^{BC_p}$

$$\begin{array}{ccc} (A^e)^{\otimes^\tau p} & \xrightarrow{n^e_A} & \\ {\scriptstyle \mathrm{id}\otimes\sigma\otimes\cdots\otimes\sigma^{p-1}}\downarrow\wr & & A^e \\ (A^e)^{\otimes^\Delta p} & \xrightarrow{m_A} & \end{array}$$

commute, where the C_p-action on $(A^e)^{\otimes^\Delta p}$ corresponding to the inclusion $BC_p \subseteq \mathcal{O}_{C_p}$ is the transposition.

The main result of this paper both formalizes and confirms the aforementioned intuitive picture.

Theorem 1.3 (Corollary 4.7 & Theorem 4.23)**.** *The canonical forgetful functor from the category of C_p-$\mathbb{E}_\infty$ algebras in C_p-spectra (Example 2.33) to the category of normed $\mathbb{E}_\infty$-algebras in C_p-spectra is an equivalence.*

A key input to the proof of Theorem 4.23 is an explicit description of the free C_p-$\mathbb{E}_\infty$ algebra in Sp^{C_p} on an $\mathbb{E}_\infty$-algebra A in Sp^{C_p}. By Theorem 4.14 and Proposition 2.15, the underlying C_p-spectrum of the free C_p-$\mathbb{E}_\infty$ algebra $F(A)$ on A is given by

$$F(A) \simeq \begin{array}{ccc} & & A^{\varphi C_p} \otimes A^e_{hC_p} \\ & & \downarrow{\scriptstyle s_A \otimes \nu_A} \\ A^e & \longmapsto & A^{tC_p} \end{array}$$

where u is the unit, $s_A : A^{\varphi C_p} \to A^{tC_p}$ is the structure map, and ν_A is the twisted Tate-valued norm (Definition 3.8).

Remark 1.4. There is an analogous statement (Theorem 5.15), proved in essentially the same way, for relative normed algebras, i.e. C_p-$\mathbb{E}_\infty$-algebras *over* a fixed C_p-$\mathbb{E}_\infty$-algebra A.

One expects an analogous result to hold for arbitrary G, but we stick with C_p here because the author's motivating example is the case $G = C_2$, and because the complexity of (3.12) seemingly grows exponentially in the subgroup lattice of G.

1.3 Applications & Examples

The power of Theorem 4.23 is that, in many cases, it is easier to identify objects in the diagram category Definition 3.11 than to produce a C_p-$\mathbb{E}_\infty$-algebra in the sense of Definition 2.32, which requires exhibiting an infinite amount of coherence data. In particular, a normed ring is the data of an $\mathbb{E}_\infty$-ring in Sp^{C_p} plus the additional datum of a commutative diagram (3.18). As an application, in §5 we show that various $\mathbb{E}_\infty$-rings in Sp^{C_p} admit natural lifts to C_p-$\mathbb{E}_\infty$-rings in Sp^{C_p}.

Corollary 1.5 (Theorem 5.1)**.** *Let k be a discrete commutative ring. The constant C_p-Mackey functor $\underline{k}$ on k acquires an essentially unique structure of a C_p-$\mathbb{E}_\infty$-ring.*

Using our main theorem, we are able to give an alternative proof of a special case of a result [Hil22, Proposition 3.3.6] of Kaif Hilman. In view of the expected correspondence between N_∞-algebras and C_p-$\mathbb{E}_\infty$-algebras, the following result should also be compared to Theorem 6.26 of [BH15].

Corollary 1.6 (Proposition 5.3)**.** *Every Borel $\mathbb{E}_\infty$-algebra in C_p-spectra admits an essentially unique refinement to a C_p-$\mathbb{E}_\infty$-algebra.*

Many examples arise in the case $p = 2$ because involutions are ubiquitous in topology. Natural examples of $\mathbb{E}_\infty$-rings in Sp^{C_2} include real topological and algebraic K-theories ([Ati66] & 5.8).

Corollary 1.7 (Corollary 5.10)**.**

- *Real topological K-theory $KU_\mathbb{R}$ admits a unique refinement to a C_2-$\mathbb{E}_\infty$ ring spectrum.*
- *If A satisfies the* homotopy limit problem*, then $K_\mathbb{R}(A)$ admits a unique refinement to a C_2-$\mathbb{E}_\infty$ ring spectrum.*

A slightly less trivial class of examples are provided by the following

Corollary 1.8 (Proposition 5.5)**.** *Let $B \in \mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp})$ be an $\mathbb{E}_\infty$-algebra. Then $N^{C_p}B$ admits a canonical structure of a C_p-$\mathbb{E}_\infty$-algebra.*

Remark 1.9. Real motivic invariants and their associated real trace theories provided the impetus for this work. In particular, Theorem 5.1 will be used in the author's upcoming work on real trace theories.

1.4 Outline

Despite the nice intuitive picture outlined in §1.1, handling the higher coherence conditions associated to n gets complicated quickly. Thus our proof strategy does not appeal directly to understanding the operadic indexing category (although we will need some understanding of this to write down a comparison functor).

In §2, we collect background on genuine equivariant homotopy theory, as well as the parametrized ∞-categorical perspective on equivariant algebras. In §3, we define normed rings. In §4.1, we define a comparison functor from parametrized algebras to normed rings. In §4.2, we exhibit a formula for the free C_p-$\mathbb{E}_\infty$-algebra on an $\mathbb{E}_\infty$-algebra. In §4.3, we show that the free C_p-$\mathbb{E}_\infty$-algebra on an $\mathbb{E}_\infty$-algebra also computes the free *normed algebra*, and conclude by the Barr–Beck–Lurie theorem. In §5, we look into a few examples and applications.

1.5 Background, Notation, & Conventions

We assume some familiarity with the language of ∞-categories (in the form of quasi-categories) as introduced by Joyal [Joy08] and developed in [Lur09]. All categories are understood to be ∞-categories unless otherwise specified. We do a cursory review of the theory of parametrized ∞-categories as developed by Barwick, Dotto, Glasman, Nardin, and Shah [Bar+16a; Bar+16b; Bar+17; Nar17; Sha18], but the reader should consult the former references for more details. We will assume some familiarity with the ∞-operads of [Lur17, Chapters 2 & 3], which we will compare to the parametrized algebras of [NS22].

To reduce visual clutter, we regularly drop subscripts such as a prime p or a (C_p-)$\mathbb{E}_\infty$-algebra A when they are understood to be fixed (e.g. within the proof of a particular proposition).

1.6 Acknowledgements

The author is indebted to Denis Nardin and Jay Shah for numerous enlightening conversations and for, in collaboration Clark Barwick, Emanuele Dotto, and Saul Glasman, setting up the foundations of parametrized ∞-categories. The author would like to thank Elden Elmanto and Noah Riggenbach for helpful conversations, and Andrew Blumberg and Elden Elmanto for feedback on an early draft. The author was supported by a NSF Graduate Research Fellowship under Grant No. DGE 2140743 during the completion of this work.

2 Background

We collect some background on genuine equivariant homotopy theory and parametrized ∞-categories here. In §2.1 and §2.3, we recall the parametrized ∞-categorical language and parametrized algebras, resp. of Barwick–Dotto–Glasman–Nardin–Shah. In §2.2, we collect background and structural results on the C_p-genuine equivariant category.

2.1 Parametrized ∞-categories

Let G be a finite group.

Recollection 2.1. The orbit category $\mathcal{O}_G$ is the category with objects finite transitive G-sets and morphisms G-equivariant maps. We let Fin_G denote the finite coproduct completion of $\mathcal{O}_G$, i.e. the category of finite G-sets and G-equivariant maps. We recall that $\mathcal{O}_G^{\mathrm{op}}$ is an *orbital* ∞-category in the sense of Definition 1.2 of [Nar17].

Definition 2.2. ([Nar17, between Examples 1.3 & 1.4; Bar+16b, Definition 1.3]) A *G-∞-category* is a cocartesian fibration $\mathcal{C} \to \mathcal{O}_G^{\mathrm{op}}$.

[Nar17, beginning of §1.2] A morphism of G-∞-categories is a functor F of ∞-categories over $\mathcal{O}_G^{\mathrm{op}}$:

$$\begin{array}{ccc} \mathcal{C} & \xrightarrow{F} & \mathcal{D} \\ & {\scriptstyle p}\searrow \quad \swarrow{\scriptstyle q} & \\ & \mathcal{O}_G^{\mathrm{op}} & \end{array}$$

which takes p-cocartesian arrows in $\mathcal{C}$ to q-cocartesian arrows in $\mathcal{D}$. We denote the category of G-functors by $\mathrm{Fun}_G(\mathcal{C}, \mathcal{D})$.

Remark 2.3. [Lur09, §3.2.2; Sha18, Example 2.5] Let $\mathcal{C}\mathrm{at}_\infty$ denote the large ∞-category of small ∞-categories. There is a universal cocartesian fibration $\mathcal{U} \to \mathcal{C}\mathrm{at}_\infty$ such that pullback induces an equivalence

$$\mathrm{Fun}(\mathcal{O}_G^{\mathrm{op}}, \mathcal{C}\mathrm{at}_\infty) \simeq \mathcal{C}\mathrm{at}^{\mathrm{cocart}}_{\infty/\mathcal{O}_G^{\mathrm{op}}}.$$

Unraveling definitions and taking $G = C_p$, a C_p-∞-category is the data of

- an ∞-category $\mathcal{C}^{C_p}$,
- an ∞-category with C_p-action $\mathcal{C}^e$, and
- a functor $\mathcal{C}^{C_p} \to \mathcal{C}^e$ which lifts along the C_p homotopy fixed points $(\mathcal{C}^e)^{hC_p} \to \mathcal{C}^e$. In particular, if $\mathcal{C}^e$ is endowed with the trivial C_p-action, then $(\mathcal{C}^e)^{hC_p} \simeq (\mathcal{C}^e)^{BC_p} \simeq \mathrm{Fun}(BC_p, \mathcal{C}^e)$ comprises objects in $\mathcal{C}^e$ with (naïve) C_p-action.

In particular, we see that a cocartesian section $\sigma\colon \mathcal{O}_{C_p}^{\mathrm{op}} \to \mathcal{C}$ is determined by its value on $\sigma(C_p/C_p)$. Informally, we regard the category of cocartesian sections of $\mathcal{C}$ as the category of objects in $\mathcal{C}$.

Notation 2.4. Going forward, we use the notation $\mathcal{T}$ for $\mathcal{O}_{C_p}^{\mathrm{op}}$ to reduce notational clutter. While most of the general theory in §2.1 and §2.3 applies to $\mathcal{T}$ a general atomic orbital ∞-category, we will not need this level of generality to formulate our main results.

There is an (internal to $\mathcal{T}$-parametrized categories) version of functor categories. The notion of *parametrized functor categories* of [Sha18, §3] will be necessary to our investigation of parametrized colimits.

Proposition 2.5. *[Sha18, Proposition 3.1; Bar+16b, Construction 5.2] Let $\mathcal{C} \to \mathcal{T}^{op}$, $\mathcal{D} \to \mathcal{T}^{op}$ be cocartesian fibrations. Then there exists a cocartesian fibration $\underline{\mathrm{Fun}}(\mathcal{C}, \mathcal{D}) \to \mathcal{T}^{op}$ such that under the straightening-unstraightening equivalence of Remark 2.3, $\underline{\mathrm{Fun}}(\mathcal{C}, \mathcal{D})$ represents the presheaf*

$$\mathcal{E} \mapsto \hom_{\mathcal{T}^{op}}(\mathcal{E} \times_{\mathcal{T}^{op}} \mathcal{C}, \mathcal{D}).$$

Notice that an object of $\underline{\mathrm{Fun}}(\mathcal{C}, \mathcal{D})$ over $t \in \mathcal{T}$ is a $(\mathcal{T}^{\mathrm{op}})_{t/}$-functor

$$(\mathcal{T}^{\mathrm{op}})_{t/} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{C} \to (\mathcal{T}^{\mathrm{op}})_{t/} \times_{\mathcal{T}^{\mathrm{op}}} \mathcal{D}.$$

Construction 2.6 ($\mathcal{T}$-category of objects)**.** [Bar+16b, Definition 7.4] Let E be a (non-parametrized) ∞-category. The product $E \times \mathcal{T}^{\mathrm{op}}$ may be regarded as a $\mathcal{T}$-∞-category via projection onto the second factor. Evaluation at the source exhibits the (non-parametrized) functor category $\mathrm{Fun}(\Delta^1, \mathcal{T}^{\mathrm{op}}) \xrightarrow{\mathrm{ev}_0} \mathcal{T}^{\mathrm{op}}$ as a cartesian fibration. The parametrized functor category of [Bar+16b, Recollection 5.1]

$$\underline{E}_{\mathcal{T}} := \underline{\mathrm{Fun}}_{\mathcal{T}^{\mathrm{op}}} \left(\mathrm{Fun}(\Delta^1, \mathcal{T}^{\mathrm{op}}), E \times \mathcal{T}^{\mathrm{op}} \right)$$

is the *$\mathcal{T}$-∞-category of $\mathcal{T}$-objects in E.*

Theorem 2.7. *[Bar+16b, Theorem 7.8] Let $\mathcal{C}$ be a $\mathcal{T}$-∞-category. Let $\mathcal{D}$ be an ∞-category. Then the $\mathcal{T}$-category of objects of Construction 2.6 satisfies*

$$\mathrm{Fun}_{\mathcal{T}^{op}}(\mathcal{C}, \underline{\mathcal{D}}) \simeq \mathrm{Fun}(\mathcal{C}, \mathcal{D}).$$

Example 2.8. Taking $E = \mathrm{Spc}$ and $\mathcal{C} = \mathcal{T}^{\mathrm{op}}$ in Theorem 2.7, we see that cocartesian sections of $\underline{\mathrm{Spc}}_{\mathcal{T}}$ correspond exactly to $\mathrm{Fun}(\mathcal{T}^{\mathrm{op}}, \mathrm{Spc})$.

We will need to know what a G-left Kan extension is. In service of keeping the background section brief, we take Remark 10.2(3) of [Sha18], which is equivalent to Definition 10.1 of *loc.cit*.

Notation 2.9. [Sha18, Notation 2.29] Let $p : \mathcal{D} \to \mathcal{T}^{\mathrm{op}}$ be a $\mathcal{T}$-∞-category. Given an object $x \in \mathcal{D}$, define

$$\underline{x} := \{x\} \times_{\mathcal{D}} \mathrm{Ar}^{cocart}(\mathcal{D}).$$

Given a $\mathcal{T}$-functor $\psi : \mathcal{C} \to \mathcal{D}$, define the *parametrized fiber of ψ over $x \in \mathcal{D}$* to be

$$\mathcal{C}_{\underline{x}} := \underline{x} \underset{\mathcal{D}, \psi}{\times} \mathcal{C}.$$

Observe that $\mathcal{C}_{\underline{x}}$ may be naturally regarded as a $(\mathcal{T}^{\mathrm{op}})^{p(x)/-}$-category.

Definition 2.10. [Sha18, Remark 10.2(3)] Suppose given a diagram of $\mathcal{T}$-∞-categories

$$\begin{array}{ccc} C & \xrightarrow{F} & E \\ {\scriptstyle\psi}\downarrow & \overset{\eta}{\Searrow} & \nearrow_{G} \\ D & & \end{array} .$$

We say that G is a *left $\mathcal{T}$-Kan extension of F along ψ* if for all $t \in \mathcal{T}$ and all $x \in D_t$, $G|_{\underline{x}}$ is a left $(\mathcal{T}^{\mathrm{op}})^{t/}$-Kan extension of $F|_{\underline{x}} : C_{\underline{x}} \to E_{\underline{t}}$ along $\psi_{\underline{x}}$.

2.2 Genuine equivariant homotopy theory

In this section, we introduce the stable C_p-genuine equivariant category, discuss a parametrized lift (Example 2.14) and give an alternative presentation (Proposition 2.15) which will be useful to our study of algebras. Finally, we recall the Hill–Hopkins–Ravenel norms.

Proposition 2.11. *Let G be a finite group. Then there exists an ∞-category* $\mathrm{Span}(\mathrm{Fin}_G)$ *having*

- *the same objects as* Fin_G
- *homotopy classes of morphisms from V to U in* $\mathrm{Span}(\mathrm{Fin}_G)$ *are in bijection with diagrams $V \leftarrow T \to U$ up to isomorphism of diagrams fixing V and U.*

- *The composite of $V \leftarrow T \to U$ and $U \leftarrow S \to W$ is equivalent to the diagram $V \leftarrow T \times_U S \to W$.*

Moreover, $\mathrm{Span}(\mathrm{Fin}_G)$ *is semiadditive, i.e. finite coproducts and products are isomorphic, and are given on underlying G-sets by the disjoint union.*

Proof. The construction of $\mathrm{Span}(\mathrm{Fin}_G)$ is [Bar17, Proposition 5.6] applied to [Bar17, Example 5.4]. The (0-)semiadditivity of $\mathrm{Span}(\mathrm{Fin}_G)$ follows from noticing that $\mathrm{Span}(\mathrm{Fin}_G)$ is a module over $\mathrm{Span}(\mathrm{Fin})$ and [Har20, Corollary 3.19]. □

The notion of a Mackey functor first appeared in [Dre71] in algebra and in [May96] in homotopy theory; the following ∞-categorical version of the definition is taken from [Nar17, §2.3].

Definition 2.12. Let G be a finite group and let $\mathrm{Span}(\mathrm{Fin}_G)$ be the span category of Proposition 2.11. Let $\mathcal{C}$ be a category which admits finite products. Then the category of $\mathcal{C}$-valued *G-Mackey functors* is given by

$$\mathrm{Mack}_G(\mathcal{C}) := \mathrm{Fun}^{\Sigma}(\mathrm{Span}(\mathrm{Fin}_G), \mathcal{C})$$

where the right-hand side denotes the full subcategory on functors which take direct sums in $\mathrm{Span}(\mathrm{Fin}_G)$ to products in $\mathcal{C}$. We will denote the category of *genuine equivariant G-spectra* by $\mathrm{Sp}^G = \mathrm{Mack}_G(\mathrm{Sp})$.

We identify the theory of orthogonal G-spectra (where weak equivalences are detected levelwise) with G-spectral Mackey functors via the equivalence established in [GM17, §3].

Recollection 2.13 (Smash product of G-Mackey functors)**.** The category $\mathrm{Span}(\mathrm{Fin}_G)$ inherits a symmetric monoidal structure from Fin_G given on underlying objects by cartesian product of finite G-sets [BGS16, Proposition 2.9]. Suppose that $\mathcal{C}$ has a presentably symmetric monoidal structure[2] $\otimes$. Then we can equip $\mathrm{Mack}_G(\mathcal{C}) = \mathrm{Fun}^{\Sigma}(\mathrm{Span}(\mathrm{Fin}_G), \mathcal{C})$ with a symmetric monoidal structure given by Day convolution [Gla16, Proposition 2.11]. When we take $\mathcal{C} = \mathrm{Sp}$ and the symmetric monoidal structure to be the smash product on spectra, this recovers the usual smash product of G-spectra.

The ∞-category of G-Mackey functors in spectra is equivalent to the category of cocartesian sections of a G-parametrized ∞-category.

Example 2.14. The G-∞-category of G-spectra $\underline{\mathrm{Sp}}^G$ is [Nar16, Definition 7.3 & Corollary 7.4.1] applied to $D = \underline{\mathrm{Spc}}^G$.

There is an alternative way of understanding $\mathrm{Mack}_{C_p}(\mathcal{C})$ as a recollement *when $\mathcal{C}$ is stable* and admits BC_p-shaped colimits. The following is [MNN17, Theorem 6.24].

Proposition 2.15. *There is an equivalence of stable ∞-categories*

$$\mathrm{Sp}^{C_p} = \mathrm{Mack}_{C_p}(\mathrm{Sp}) \to \mathrm{Sp}^{BC_p} \times_{\mathrm{Sp}} Ar(\mathrm{Sp})$$
$$X \mapsto \left(X^e, \mathrm{cofib}\left((X^e)_{hC_p} \xrightarrow{\mathrm{tr}} X^{C_p}\right) \to (X^e)^{tC_p}\right)$$

where the map $Ar(\mathrm{Sp}) \to \mathrm{Sp}$ is evaluation at the target. We call $X^{\varphi C_p} := \mathrm{cofib}\left((X^e)_{hC_p} \xrightarrow{\mathrm{tr}} X^{C_p}\right)$ the C_p-geometric fixed points *of X.*

[2] That is, the tensor product commutes with (small) colimits separately in each variable.

Notation 2.16. We will denote the projection $\mathrm{Sp}^{C_p} \to \mathrm{Ar}(\mathrm{Sp})$ by $s_{(-)}$, i.e. for any C_p-spectrum A we have a map $s_A \colon A^{\varphi C_p} \to A^{tC_p}$.

It will be convenient to know that the recollement of Proposition 2.15 is compatible with symmetric monoidal structures.

Proposition 2.17. *Let C_p be a cyclic group of prime power order. Then the recollement of Notation 2.15 is a symmetric monoidal recollement in the sense of [Sha21, Definition 2.20].*

Corollary 2.18. *Let C_p be a cyclic group of prime power order. Then there is an equivalence of ∞-categories*

$$\mathrm{Alg}_{\mathbb{E}_\infty}\mathrm{Sp}^{C_p} \xrightarrow{\sim} \mathrm{Alg}_{\mathbb{E}_\infty}\mathrm{Sp}^{BC_p} \times_{\mathrm{Alg}_{\mathbb{E}_\infty}\mathrm{Sp}} Ar(\mathrm{Alg}_{\mathbb{E}_\infty}\mathrm{Sp})$$

such that applying forgetful functors recovers the equivalence of Proposition 2.15.

Proof. The corollary follows from [Sha21, Theorem 1.2] and the definition of $\mathbb{E}_\infty$-algebras. □

Observation 2.19. Now suppose $A, B \in \mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)$. Then the morphism space is computed as

$$\hom_{\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{C_p})}(A,B) \simeq \hom_{\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{BC_p})}(A^e,B^e) \underset{\hom_{\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp})}(A^{tC_p},B^{tC_p})}{\times} \hom_{\mathrm{Ar}(\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}))}\begin{pmatrix} A^{\varphi C_p} & & B^{\varphi C_p} \\ \downarrow & , & \downarrow \\ A^{tC_p} & & B^{tC_p}\end{pmatrix}$$

Recollection 2.20 (Tate diagonal)**.** [NS18, Definition III.1.4] The Tate diagonal is a natural transformation $\mathrm{id} \to (-^{\otimes p})^{tC_p}$ of exact functors $\mathrm{Sp} \to \mathrm{Sp}$ where C_p acts on $(A)^{\otimes p}$ via a cyclic permutation.

Recollection 2.21. Given a subgroup inclusion $H \subset G$, the Hill–Hopkins–Ravenel norm [HHR16, Definition A.52] is a (non-exact) functor

$$N_H^G : \mathrm{Sp}^H \to \mathrm{Sp}^G.$$

When $H = \{e\} \subseteq G = C_p$, the norm is uniquely characterized by the existence of natural equivalences $\left(N_e^{C_p}X\right)^{\varphi C_p} \simeq X$ in $\mathrm{Sp}^{\{e\}} \simeq \mathrm{Sp}$ and $\left(N_e^{C_p}X\right)^e \simeq X^{\otimes p}$ in Sp^{BC_p}, where C_p acts on the smash product by permuting the terms. The connecting map $X \to (X^{\otimes p})^{tC_p}$ is given by the Tate diagonal of [NS18, Theorem 1.7]. The functor N_H^G enjoys the properties of being symmetric monoidal and it preserves sifted colimits [HHR16, Proposition A.54], so it lifts to a functor [HHR16, Proposition A.56]

$$N_H^G : \mathrm{Alg}_{\mathbb{E}_\infty}\mathrm{Sp}^H \to \mathrm{Alg}_{\mathbb{E}_\infty}\mathrm{Sp}^G.$$

Lemma 2.22. *The Hill–Hopkins–Ravenel norm $N^{C_p} : \mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}) \to \mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)$ preserves all small colimits.*

Proof. By [BH21, Lemma 2.8], it suffices to show that N^{C_p} preserves sifted colimits and finite coproducts. The norm N^{C_p} preserves sifted colimits of algebras because they are computed at the level of underlying spectra, and N^{C_p} preserves finite coproducts of algebras because it is symmetric monoidal with respect to the smash product on Sp and Sp^{C_p} (Recollections 2.2 & 2.21). □

2.3 C_p-$\mathbb{E}_\infty$-rings

In this section we introduce the genuine equivariant algebraic structures of interest via the formalism of parametrized operads of Nardin–Shah [NS22]. We fix notation for the remainder of the paper.

Notation 2.23. Let p be a prime and let $\mathcal{T}$ denote the orbital ∞-category $\mathcal{O}_{C_p}$ of Recollection 2.1.

Definition 2.24. The category $\underline{\mathrm{Fin}}_{\mathcal{T}} = \underline{\mathrm{Fin}}_{C_p}$ of *parametrized $\mathcal{T}$-sets* is the $\mathcal{T}$-∞-category classified by the functor $V \mapsto \mathrm{Fin}_{\mathcal{T}/V}$. Equivalently, it is described by the fiber product $\mathrm{Ar}\left(\mathrm{Fin}_{\mathcal{T}/V}\right) \times_{\mathrm{Fin}_{\mathcal{T}}} \{V\}$. The category $\underline{\mathrm{Fin}}_{\mathcal{T},*}$ of *parametrized pointed $\mathcal{T}$-sets* is the $\mathcal{T}$-∞-category classified by the functor $V \mapsto \left(\mathrm{Fin}_{\mathcal{T}/V}\right)_{\mathrm{id}_V/}$.

$$\underline{\mathrm{Fin}}^{v}_{\mathcal{T}} := \mathrm{Ar}\left(\mathrm{Fin}_{\mathcal{T}/V}\right) \underset{\mathrm{Fin}_{\mathcal{T}}}{\times} \mathcal{T}$$

Example 2.25. We unpack the definition in the case $\mathcal{T} = \mathcal{O}_{C_p}$. For each orbit, the fiber is given by

$$(\underline{\mathrm{Fin}}^{v}_{\mathcal{T}})_{C_p/C_p} \simeq \mathrm{Fin}_{C_p} \qquad (\underline{\mathrm{Fin}}^{v}_{\mathcal{T}})_{C_p} \simeq \mathrm{Fin}^{Free}_{C_p}$$

and the morphism $C_p/C_p \leftarrow C_p$ classifies the functor $\mathrm{Fin}_{C_p} \to \mathrm{Fin}^{Free}_{C_p}$, $V \mapsto V \times_{C_p/C_p} C_p$.

Definition 2.26. [NS22, Definition 2.1.2] Let $\mathcal{T}$ be an atomic orbital ∞-category. The ($\mathcal{T}$-parametrized) ∞-category of *finite pointed $\mathcal{T}$-sets* is

$$\underline{\mathrm{Fin}}_{\mathcal{T},*} = \mathrm{Span}\left(\underline{\mathrm{Fin}}^{v}_{\mathcal{T}}, (\underline{\mathrm{Fin}}^{v}_{\mathcal{T}})^{si}, (\underline{\mathrm{Fin}}^{v}_{\mathcal{T}})^{tdeg}\right).$$

where a morphism $[\phi : f \to g]$ of $\underline{\mathrm{Fin}}^{v}_{\mathcal{T}}$

$$\begin{array}{ccc} U & \xrightarrow{h} & X \\ f\downarrow & & \downarrow g \\ V & \xrightarrow{k} & Y \end{array}$$

- belongs to $(\underline{\mathrm{Fin}}^{v}_{\mathcal{T}})^{tdeg}$ if k is degenerate, and
- belongs to $(\underline{\mathrm{Fin}}^{v}_{\mathcal{T}})^{si}$ if $U \to V \times_Y X$ is a summand inclusion.

Definition 2.27. [NS22, Definition 2.1.7] A *$\mathcal{T}$-∞-operad* is a pair $(\mathcal{C}^{\otimes}, p)$ consisting of a $\mathcal{T}$-∞-category $\mathcal{C}^{\otimes}$ and a $\mathcal{T}$-functor $p : \mathcal{C}^{\otimes} \to \underline{\mathrm{Fin}}_{\mathcal{T},*}$ which is a categorical fibration and satisfies the following additional conditions

(1) For every inert morphism $\psi : f_+ \to g_+$ of $\underline{\mathrm{Fin}}_{\mathcal{T},*}$ and every object $x \in \mathcal{C}^{\otimes}_{f_+}$, there is a p-cocartesian edge $x \to y$ covering ψ.

(2) For any object $f_+ = [U_+ \to V]$ of $\underline{\mathrm{Fin}}_{\mathcal{T},*}$, the p-cocartesian edges lying over the characteristic morphisms

$$\left\{\chi_{[W\subseteq U]} : f_+ \to I(W)_+ \mid W \in \mathrm{Orbit}(U)\right\}$$

together induce an equivalence

$$\prod_{W\in\mathrm{Orbit}(U)} \left(\chi_{[W\subseteq U]}\right)_! : \mathcal{C}^{\otimes}_{f_+} \xrightarrow{\sim} \prod_{W\in\mathrm{Orbit}(U)} \mathcal{C}^{\otimes}_{I(W)_+}.$$

(3) For any morphism
$$\psi\colon f_+ = [U_+ \to V] \to g_+ = [U'_+ \to V']$$
of $\underline{\mathrm{Fin}}_{\mathcal{T},*}$, objects $x \in \mathcal{C}^{\otimes}_{f_+}$ and $y \in \mathcal{C}^{\otimes}_{g_+}$, and any choice of p-cocartesian edges
$$\{y \to y_W \mid W \in \mathrm{Orbit}(U')\}$$
lying over the characteristic morphisms
$$\left\{\chi_{[W \subseteq U]} : g_+ \to I(W)_+ \mid W \in \mathrm{Orbit}(U')\right\},$$
the induced map
$$\mathrm{Map}^{\psi}_{\mathcal{C}^{\otimes}}(x, y) \xrightarrow{\sim} \prod_{W \in \mathrm{Orbit}(U')} \mathrm{Map}^{\chi_{[W \subseteq U']} \circ \psi}_{\mathcal{C}^{\otimes}}(x, y_W)$$
is an equivalence.

Given a $\mathcal{T}$-∞-operad $(\mathcal{C}^{\otimes}, p)$, its *underlying* $\mathcal{T}$*-∞-category* is the fiber product
$$\mathcal{C} := \mathcal{T}^{\mathrm{op}} \underset{\underline{\mathrm{Fin}}_{\mathcal{T},*}}{\times} \mathcal{C}^{\otimes}.$$

[NS22, Definition 2.1.8] Given a $\mathcal{T}$-∞-operad $(\mathcal{C}^{\otimes}, p)$, an edge of $\mathcal{C}^{\otimes}$ is *inert* if it is p-cocartesian over an inert edge of $\underline{\mathrm{Fin}}_{\mathcal{T},*}$, and it is *active* if it factors as a p-cocartesian edge followed by an edge lying over a fiberwise active edge in $\underline{\mathrm{Fin}}_{\mathcal{T},*}$.

Example 2.28 (Indexing systems)**.** Let us recall that the C_p-$\mathbb{E}_\infty$-operad is given by $\mathrm{Com}^{\otimes}_{C_p} = \underline{\mathrm{Fin}}_{C_p,*}$ the $\mathcal{O}_{C_p}$-operad corresponding to the maximal indexing system [NS22, Example 2.4.7]. The minimal indexing system $\mathrm{Com}^{\otimes}_{\mathcal{O}^{\simeq}_{C_p}}$ is a C_p-∞ operad with underlying category the wide subcategory of $\underline{\mathrm{Fin}}_{\mathcal{O}_{C_p},*}$ containing those morphisms
$$\begin{array}{ccccc} U & \longleftarrow & Z & \xrightarrow{m} & X \\ \downarrow & & \downarrow & & \downarrow \\ V & \longleftarrow & Y & = & Y \end{array}$$
where m is a coproduct of (possibly empty) fold maps. The structure map is the natural inclusion $\mathrm{Com}^{\otimes}_{\mathcal{O}^{\simeq}_{C_p}} \subseteq \mathrm{Com}^{\otimes}_{C_p}$.

Definition 2.29. [NS22, Definition 2.2.3] Let $p : \mathcal{C}^{\otimes} \to \underline{\mathrm{Fin}}_{\mathcal{T},*}$ be a fibration of $\mathcal{T}$-∞-operads in which p is moreover a cocartesian fibration. Then we will call $\mathcal{C}^{\otimes}$ a $\mathcal{T}$*-symmetric monoidal* $\mathcal{T}$*-∞-category*.

Recollection 2.30. [NS22, Example 2.4.2; BH21, §9] The C_p-∞-category of C_p-spectra is endowed with a C_p-symmetric monoidal structure via the Hill–Hopkins–Ravenel norm functors as follows: Example 2.4.2 [NS22] and §9 of [BH21] define a functor
$$\begin{aligned} \zeta := \mathbf{SH}^{\otimes} \circ \omega_{C_p} : \mathrm{Span}(\mathrm{Fin}_{C_p}) &\to \mathrm{Alg}_{\mathbb{E}_1}(\mathfrak{C}\mathrm{at}) \\ T &\mapsto \mathbf{SH}^{\otimes} \circ \omega_{C_p}(T) \end{aligned}.$$

Unravelling definitions, this functor takes

$$
\begin{aligned}
\zeta\colon (C_p \twoheadrightarrow C_p/C_p) &\mapsto \mathrm{Sp}^{BC_p} \\
: (C_p = C_p) &\mapsto \mathrm{Sp}^{BC_p} \\
: (C_p/C_p = C_p/C_p) &\mapsto \mathrm{Sp}^{C_p} \\
: \begin{array}{ccc} C_p/C_p & \longleftarrow & C_p \\ \| & & \downarrow \\ C_p/C_p & = & C_p/C_p \end{array} &\mapsto \begin{array}{c} \mathrm{Sp}^{C_p} \\ \downarrow {\scriptstyle (-)^e} \\ \mathrm{Sp}^{BC_p} \end{array} \\
: \begin{array}{ccc} C_p & \longrightarrow & C_p/C_p \\ \downarrow & & \| \\ C_p/C_p & = & C_p/C_p \end{array} &\mapsto \begin{array}{c} \mathrm{Sp} \\ \downarrow {\scriptstyle N^{C_p}} \\ \mathrm{Sp}^{C_p} \end{array} \\
: \begin{array}{ccc} C_p & = & C_p \\ \downarrow & & \| \\ C_p/C_p & \longleftarrow & C_p \end{array} &\mapsto \begin{array}{c} \mathrm{Sp}^{BC_p} \\ \downarrow {\scriptstyle \mathrm{id}} \\ \mathrm{Sp}^{BC_p} \end{array}
\end{aligned}
\quad . \tag{2.31}
$$

Under Theorem 2.3.9 of [NS22], this corresponds to a cocartesian fibration $p : \int \zeta := \left(\underline{\mathrm{Sp}}^{C_p}\right)^{\otimes} \to \underline{\mathrm{Fin}}_{C_p,*}$.

In this paper we use the notion of a C_p-$\mathbb{E}_\infty$-*ring* in the sense of Nardin–Shah [NS22, Definition 2.2.1].

Definition 2.32. Let $\mathcal{C}^{\otimes}, \mathcal{D}^{\otimes} \to \mathcal{O}^{\otimes}$ be fibrations of C_p-∞-operads. A $\mathcal{T}$-functor $p : \mathcal{C}^{\otimes} \to \mathcal{D}^{\otimes}$ is *a morphism of $\mathcal{T}$-∞-operads over $\mathcal{O}$* if p takes inert morphisms in $\mathcal{C}^{\otimes}$ to inert morphisms in $\mathcal{D}^{\otimes}$. Then the category of *$\mathcal{C}^{\otimes}$-algebras in $\mathcal{D}$*

$$\underline{\mathrm{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{D})$$

is the full $\mathcal{T}$-subcategory of $\underline{\mathrm{Fun}}_{\mathcal{T}}(\mathcal{C}, \mathcal{D})$ on the morphisms of $\mathcal{T}$-∞-operads over $\mathcal{O}$. We write $\mathrm{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{D})$ for the (ordinary) ∞-category of $\mathcal{T}$-objects in $\underline{\mathrm{Alg}}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{D})$.

When $\mathcal{O}$ and/or $\mathcal{C}$ are equivalent to $\underline{\mathrm{Fin}}_{\mathcal{T},*}$, we drop them from notation.

We write $\mathrm{Alg}_{\underline{\mathrm{Fin}}_{C_p,*}}\left(\underline{\mathrm{Fin}}_{C_p,*}, \left(\underline{\mathrm{Sp}}^{C_p}\right)^{\otimes}\right) =: C_p\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)$.

Example 2.33. The category of C_p-$\mathbb{E}_\infty$-rings in C_p-spectra is $C_p\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{C_p})$ the space of sections of $p\colon \left(\underline{\mathrm{Sp}}^{C_p}\right)^{\otimes} \to \underline{\mathrm{Fin}}_{C_p,*}$ (Recollection 2.30) which take inert morphisms to inert morphisms.

The inclusion $\mathrm{Com}^{\otimes}_{\mathcal{T}^{\simeq}} \subseteq \mathrm{Com}^{\otimes}_{\mathcal{T}}$ of Example 2.28 induces a forgetful map

$$G\colon \mathrm{Alg}_{\mathcal{T}}\left(\mathrm{Com}_{C_p}, \mathcal{D}\right) \to \mathrm{Alg}_{\mathcal{T}}\left(\mathrm{Com}_{\mathcal{O}^{\simeq}_{C_p}}, \mathcal{D}\right). \tag{2.34}$$

The discussion immediately following [NS22, Theorem 4.3.4] is summarized by the following result.

Theorem 2.35. *Suppose $p : \mathcal{C}^{\otimes} \to \mathcal{O}^{\otimes}$ is a fibration of $\mathcal{T}$-∞-operads, and let $\mathcal{E}^{\otimes} \to \mathcal{O}^{\otimes}$ be a $\mathcal{T}$-∞-operad. Then the restriction functor*

$$p^* \colon \mathrm{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{E}) \to \mathrm{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{C},\mathcal{E})$$

admits a left adjoint $p_!$.

Definition 2.36. Suppose $p : \mathcal{C}^{\otimes} \to \mathcal{O}^{\otimes}$ is a fibration of $\mathcal{T}$-∞-operads, and let $\mathcal{E}^{\otimes} \to \mathcal{O}^{\otimes}$ be a $\mathcal{T}$-∞-operad. Let $A : \mathcal{C}^{\otimes} \to \mathcal{E}^{\otimes}$ be an $\mathcal{O}$-algebra map. Then the $\mathcal{O}$-algebra map $p_! A$ of Theorem 2.35 will be referred to as the *$\mathcal{T}$-operadic left Kan extension* of A.

Remark 2.37. [NS22, Remark 4.0.1] Definition 2.36 specializes to the theory of operadic left Kan extensions of [Lur17, §3.1.2] when $\mathcal{T} = \Delta^0$.

3 Normed rings

In defining the category of C_p-normed rings, §1.1 guides how we axiomatize the information contained in a C_p-$\mathbb{E}_\infty$ ring. We will see that this information is most naturally captured as the limit of a diagram of ∞-categories (Definition 3.11). We then exhibit a formula for mapping spaces in normed rings which will be used in the proof of our main theorem (in particular see Proposition 4.25). Finally, we close out this section by showing in Proposition 3.21 that the category of normed $\mathbb{E}_\infty$-rings is monadic over the category of ordinary $\mathbb{E}_\infty$-algebras.

3.1 Preliminaries

Construction 3.1. Consider the functor

$$\begin{aligned} |-| \colon \mathcal{O}_{C_p} &\to \mathrm{Fin}_* \\ C_p &\mapsto \langle p \rangle \\ C_p/C_p &\mapsto \langle 1 \rangle \end{aligned}$$

which takes the underlying set of a set-with-C_p-action. Since Span(Fin) is 0-semiadditive, the composite $\mathcal{O}_{C_p} \to \mathrm{Fin}_* \subset \mathrm{Span}(\mathrm{Fin})$ induces $\mathrm{Span}\left(\mathcal{O}_{C_p}^{\sqcup}, fold, all\right) \to \mathrm{Span}(\mathrm{Fin})$ which restricts to

$$m := - \times |-| \colon \mathrm{Fin}_* \times \mathcal{O}_{C_p} \to \mathrm{Fin}_*.$$

Denote the adjoint of m by $m^\dagger \colon \mathrm{Fin}_* \to \mathrm{Fun}(\mathcal{O}_{C_p}, \mathrm{Fin}_*)$. Given a symmetric monoidal ∞-category $q \colon \mathcal{C}^{\otimes} \to \mathrm{Fin}_*$, the induced map

$$\mathrm{Fun}_{\mathrm{Fin}_*}\left(\mathcal{O}_{C_p}, \mathcal{C}^{\otimes}\right)^{\otimes} := \mathrm{Fun}\left(\mathcal{O}_{C_p}, \mathcal{C}^{\otimes}\right) \underset{\mathrm{Fun}\left(\mathcal{O}_{C_p}, \mathrm{Fin}_*\right), m^\dagger}{\times} \mathrm{Fin}_* \to \mathrm{Fin}_*$$

is a cocartesian fibration of ∞-operads (cf. [Lur17, Remark 2.1.3.4]). Since $\mathcal{C}^{\otimes}$ is symmetric monoidal, given any morphism $h \colon X \to Y$ in $\mathcal{O}_{C_p}$ and any lift $\tilde{X}$ of $|X|$, there is a q-cocartesian morphism $\tilde{h}$ lifting $|h|$, so by [Lur09, Proposition 2.4.4.2] there is a functor

$$\mathrm{Fun}_{\mathrm{Fin}_*}\left(\mathcal{O}_{C_p}, \mathcal{C}^{\otimes}\right) \to \mathrm{Fun}\left(\mathcal{O}_{C_p}, \mathcal{C}\right).$$

Restriction along m induces a functor which we also denote by

$$m_{(-)} \colon \mathbb{E}_\infty \mathrm{Alg}\left(\mathcal{C}^{\otimes}\right) \to \mathrm{Fun}\left(\mathcal{O}_{C_p}, \mathbb{E}_\infty \mathrm{Alg}(\mathcal{C}^{\otimes})\right). \tag{3.2}$$

Informally, m takes an $\mathbb{E}_\infty$-algebra A to the $\mathcal{O}_{C_p}$-diagram $m_A \colon A^{\otimes p} \to A$.

Notation 3.3. The prime p is left implicit in the notation m_A of Construction 3.1, and when A is understood it may also be dropped from notation.

Remark 3.4. The parametrized norm map $n_A \colon N^{C_p}(A^e) \to A$ is *invariant* with respect to the C_p-action coming from A^e. On the other hand, $(A^e)^{\otimes p}$ has a C_p-action via cyclic permutations and n_A^e may also be regarded as a C_p-equivariant map. The reader is warned to remember the distinction between these two C_p-actions; the following observations clarify how these actions interact differently with the structure maps inherent to a C_p-$\mathbb{E}_\infty$-algebra.

Notation 3.5. Let $A \in \mathrm{Sp}^{BC_p}$ and let $\sigma \in C_p$ be a generator. Write $A^{\otimes^\Delta p}$ for the object in $\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{BC_p})$ with the *diagonal* action, i.e. the composite

$$\mathbb{E}_\infty \mathrm{Alg}\left(\mathrm{Sp}\right)^{BC_p} \xrightarrow{R \circ m} \mathbb{E}_\infty \mathrm{Alg}\left(\mathrm{Sp}\right)^{BC_p \times BC_p} \xrightarrow{\Delta^*} \mathbb{E}_\infty \mathrm{Alg}\left(\mathrm{Sp}\right)^{BC_p} \tag{3.6}$$

where m is (3.2), R is restriction along the inclusion $BC_p \subseteq \mathcal{O}_{C_p}$, and Δ^* is restriction along the diagonal $\Delta : BC_p \to BC_p \times BC_p$. Informally, we regard $A^{\otimes^\Delta p}$ as being equipped with the C_p-action where σ acts by $\sigma(a_1 \otimes \cdots \otimes a_p) = \sigma(a_p) \otimes \sigma(a_1) \otimes \cdots \otimes \sigma(a_{p-1})$. Write $A^{\otimes^\tau p}$ for the object in $\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{BC_p})$ with the *transposition* action, i.e. the same definition as in (3.6) but with the map $\{e\} \times \mathrm{id} \colon BC_p \to BC_p \times BC_p$ instead of Δ. Informally, we regard $A^{\otimes^\tau p}$ as being equipped with the C_p-action where σ acts by $\sigma(a_1 \otimes \cdots \otimes a_p) = a_p \otimes a_1 \otimes \cdots \otimes a_{p-1}$.

Observation 3.7. Let $A \in \mathrm{Sp}^{BC_p}$.

(1) The shear endomorphism $sh := \mathrm{id}_A \otimes \sigma \otimes \cdots \otimes \sigma^{p-1}$ of $A^{\otimes p} \in \mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp})$ promotes to an equivalence $A \otimes^\Delta A \to A \otimes^\tau A$ in $\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp})^{BC_p}$–in particular it is C_p-equivariant.

(2) Moreover, the Tate diagonal $A \to (A^{\otimes^\tau p})^{tC_p}$ is equivariant with respect to the given C_p-action on the source and the diagonal C_p-action on the target.

Definition 3.8. Let $A \in \mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{BC_p}\right)$. The *Tate-valued norm* is the $\mathbb{E}_\infty$-ring map defined by the composite

$$\nu_A : A \xrightarrow{\Delta} \left(A^{\otimes^\tau p}\right)^{tC_p} \xrightarrow{sh} \left(A^{\otimes^\Delta p}\right)^{tC_p} \xrightarrow{m^{tC_p}} A^{tC_p}$$

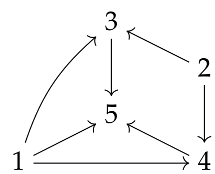
where Δ is the Tate diagonal of Recollection 2.20 and sh is the shear equivalence of Observation 3.7. In particular, it is C_p-equivariant with respect to the given action on A, the diagonal C_p-action on $(A^{\otimes^\tau_S p})$, and the *trivial* action on A^{tC_p}. We regard ν_A as a morphism $A_{hC_p} \to A^{tC_p}$, or equivalently as an object of $\mathrm{Fun}\left(\mathcal{O}_{C_p}, \mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp})\right)$.

Remark 3.9. Informally, we think of the Tate-valued norm as being $a \mapsto a\gamma(a) \cdots \gamma^{p-1}(a)$, which is a ring homomorphism modulo transfers. Note that when A is equipped with the trivial C_p-action, this is simply the ordinary Tate-valued Frobenius (compare Definition IV.1.1 of [NS18]).

3.2 Definition and properties

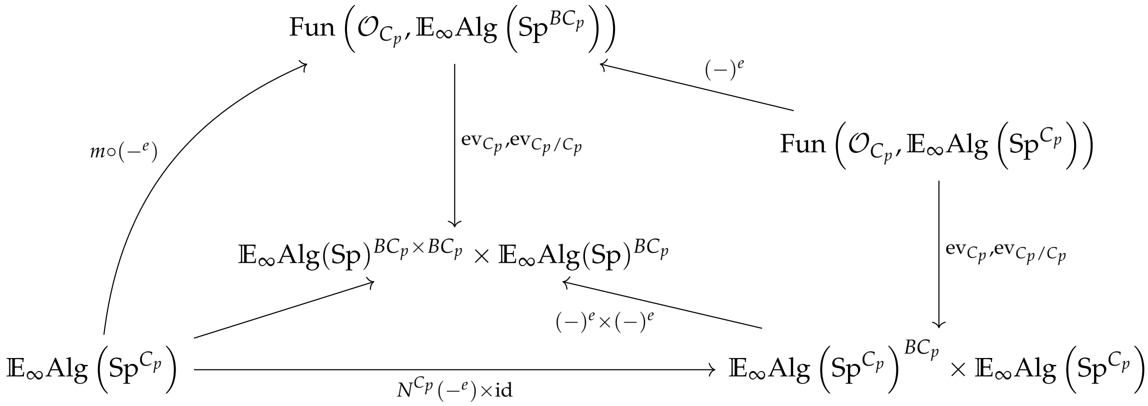
We introduce some notation for the indexing category.

Notation 3.10. Let K denote the ∞-categorical nerve of the 1-category



in which all triangles and squares commute.

Definition 3.11. Consider the diagram $\mathcal{N}\colon K \to \mathcal{C}\mathrm{at}_\infty$ where K is as in Notation 3.10:



(3.12)

where m is the functor of (3.2). Observe that the right-hand trapezoid of (3.12) commutes essentially by definition, and the leftmost triangle commutes because $\left(N^{C_p}A\right)^e \simeq (A^e)^{\otimes p}$. We define the category of *normed* C_p-$\mathbb{E}_\infty$-rings to be the limit of the diagram

$$N\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) := \lim_K \mathcal{N}. \tag{3.13}$$

There is a canonical forgetful functor $G'\colon N\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) \to \mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)$ given by the canonical projection to the lower left corner of the diagram (3.12).

Notation 3.14. Write $p_i\colon N\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) \to \mathcal{N}(i)$ for the canonical projection functors.

We will often abuse notation and abbreviate an object of $N\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)$ as a pair $(A, n_A : N^{C_2}A \to A)$ (suppressing the data of the equivalence $n_A^e \simeq m_{A^e}$).

Remark 3.15. Note that all categories in (3.12) are presentable and all functors are left adjoints (Lemma 2.22), so by [Lur09, Proposition 5.5.3.13] we may take the limit in either Pr^L or $\mathcal{C}\mathrm{at}_\infty$.

Proposition 3.16. *The category $N\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)$ can be equivalently described as the limit of the diagram*

$$\begin{array}{ccccc}
 & & \mathrm{Fun}\left(\mathcal{O}_{C_p}, \mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp})\right) & \xleftarrow{\mathrm{ev}_1} & \mathrm{Fun}\left(\mathcal{O}_{C_p}, \mathrm{Ar}(\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}))\right) \\
 & {\scriptstyle m^{tC_p}:(-^e)^{\otimes p}\to(-^e)} \nearrow & \downarrow{\scriptstyle \mathrm{ev}_{C_p},\mathrm{ev}_*} & & \downarrow{\scriptstyle \mathrm{ev}_{C_p},\mathrm{ev}_*} \\
 & & \mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp})^{BC_p}\times\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}) & \xleftarrow{\mathrm{ev}_1} & \\
\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) & \nearrow & \xrightarrow[((-)^{\varphi C_p}\to(-)^{tC_p})\circ(N^{C_p}\times id)]{} & & \mathrm{Ar}\left(\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{BC_p}\right)\right)\times\mathrm{Ar}\left(\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}\right)\right)
\end{array}$$

Proof. Follows from Corollary 2.18. □

Remark 3.17. Recall the description of a limit of ∞-categories given by Corollary 3.3.3.2 of [Lur09]. Combining this with the description of mapping spaces in $\mathrm{Alg}_{\mathbb{E}_\infty}\left(\mathrm{Sp}^{C_p}\right)$ which is a consequence of Corollary 2.18, we may equivalently characterize a normed $\mathbb{E}_\infty$-ring as the data of a $\mathbb{E}_\infty$-algebra A in Sp^{C_p} plus the data of a factorization $n_A^{\varphi C_p}$ in $\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp})$ and a 2-cell making the diagram

$$\begin{array}{ccc}
A & \xrightarrow{n_A} & A^{\varphi C_2} \\
{\scriptstyle\Delta}\downarrow & & \downarrow{\scriptstyle\alpha} \\
\left(A^{\otimes^\tau p}\right)^{tC_p} & \xrightarrow{m^{tC_p}\circ(sh)} & A^{tC_p}
\end{array} \tag{3.18}$$

commute such that, considered as a morphism $g : \Delta \to \alpha$, g is equivariant with respect to the given C_p-action on the source and the trivial C_p-action on the target. Note that the composite of the left arrow followed by the lower arrow in (3.18) is the Tate-valued norm of Definition 3.8.

When C_p acts trivially on A^e, it suffices to produce the 2-cell (3.18). More formally, given a choice of multiplication map $m : A^{\otimes^\Delta p} \to A$, by Corollary 2.18 we have an equivalence of fibers

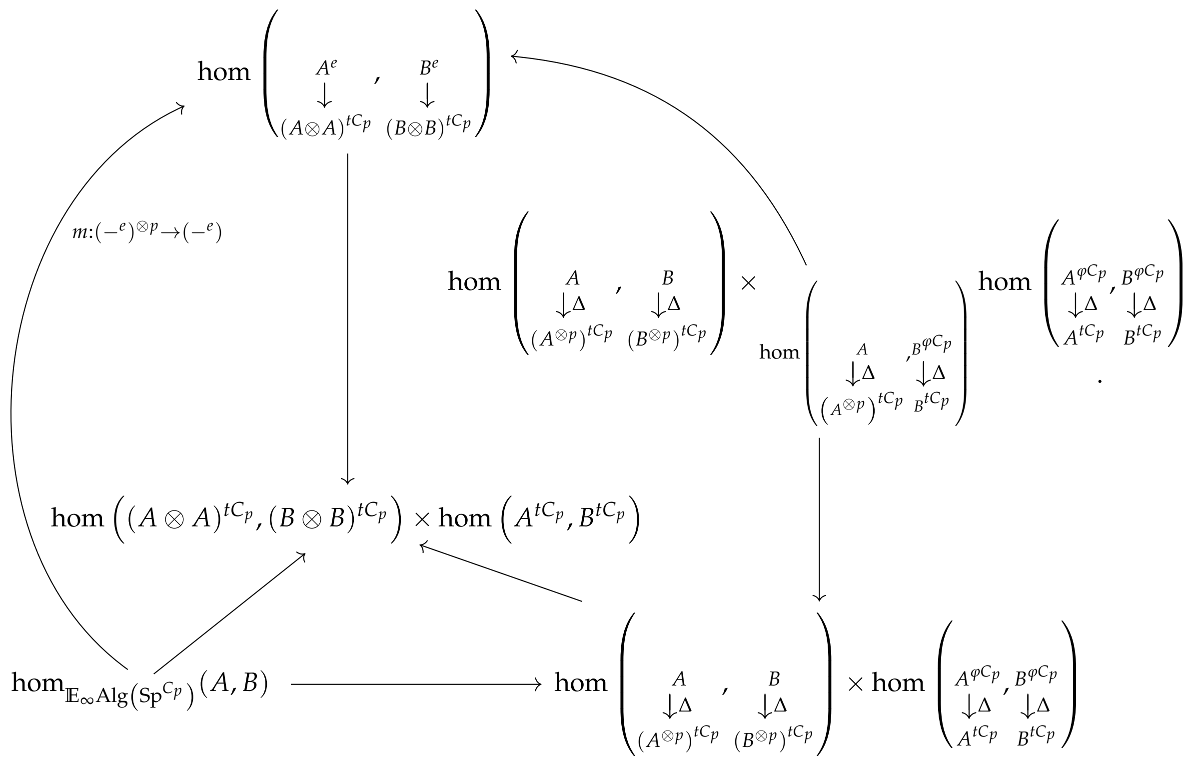
$$\mathrm{fib}_{\{m\}}\left(\hom_{\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{C_p})^{BC_p}}\left(N^{C_p}(A^e), A\right) \xrightarrow{(-)^e} \hom_{\mathbb{E}_\infty\mathrm{AlgSp}^{BC_p\times BC_p}}\left((A^e)^{\otimes^\Delta p}, A^e\right)\right)$$

$$\simeq \mathrm{fib}_{\{m^{tC_p}\}}\left\{\hom_{\mathbb{E}_\infty\mathrm{Alg}^{\Delta^1\times BC_p}}\left(\begin{array}{cc} A^e & A^{\varphi C_p} \\ \downarrow{\scriptstyle\Delta} & \downarrow{\scriptstyle\alpha} \\ \left(A^{\otimes^\tau_{\mathrm{S}} p}\right)^{tC_p}, & A^{tC_p}\end{array}\right) \xrightarrow{\mathrm{ev}_1} \hom_{\mathbb{E}_\infty\mathrm{Alg}^{BC_p}}\left(\left(A^{\otimes^\tau_{\mathrm{S}} p}\right)^{tC_p}, A^{tC_p}\right)\right\}.$$

Observation 3.19 (Morphism spaces in normed algebras)**.** Let $s, t\colon K \to \int\mathcal{N}$ be objects in the limit $N\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{C_p})$, which we identify as spaces of coCartesian sections of $\int\mathcal{N} \to K$ where

$\mathcal{N}\colon K \to \mathcal{C}\mathrm{at}_\infty$ is the diagram defining (3.12). Now by definition of a limit of ∞-categories, we may write the space of morphisms from s to t in $N\mathbb{E}_\infty$ as $\lim_k \hom_{F(k)}(s(k), t(k))$.

Unravelling definitions, given a pair $(A, n_A\colon N^{C_p}A \to A), (B, n_B\colon N^{C_p}B \to B)$ in the limit of (3.12), the morphism space $\mathrm{Hom}_{N\mathbb{E}_\infty}((A, n_A\colon N^{C_p}A \to A), (B, n_B\colon N^{C_p}B \to B))$ is computed as the limit of the diagram



(3.20)

Proposition 3.21. *The forgetful functor $G'\colon N\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) \to \mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)$ of Definition 3.11 is monadic.*

Proof. The functor G' is conservative by inspection.

Recall our notation $p_i\colon N\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{C_p}) \to \mathcal{N}(i)$ for the canonical projection functors. Now suppose given a simplicial object $A\colon \Delta^{\mathrm{op}} \to N\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)$ which is G'-split. Then in particular $p_0 \circ A$ is a colimit diagram of $\mathbb{E}_\infty$-algebras in Sp^{C_p}. Since the norm preserves all colimits of algebras by Lemma 2.22, $p_4 \circ A \simeq (N^{C_p} \times \mathrm{id}) \circ p_0 \circ A$ is a colimit diagram. By [Lur17, Corollary 5.1.2.3(2)] applied to $S = \mathcal{O}_{C_p}$, $p_2 \circ A$ is a colimit diagram. Now by Remark 3.15 and Proposition 5.1.2.2(2) of *loc. cit.* applied to $S = K$, A is a colimit diagram in $N\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{C_p})$, and said colimit is preserved by G'. Thus G' is monadic by the Barr–Beck–Lurie theorem [Lur17, Theorem 4.7.3.5]. $\square$

4 Comparing C_p-$\mathbb{E}_\infty$ and normed rings

In §4.1 we write down a functor from C_p-$\mathbb{E}_\infty$-algebras to normed C_p-algebras. Our proof strategy will be to show that the comparison functor of Corollary 4.7 exhibits both C_p-$\mathbb{E}_\infty$-algebras and normed $\mathbb{E}_\infty$-algebras as categories of algebras over the *same* monad on $\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)$, then appeal to a variant of the Barr–Beck–Lurie theorem. In §4.2 we exhibit a formula for the free C_p-$\mathbb{E}_\infty$-algebra on an $\mathbb{E}_\infty$-algebra, then we show in §4.3 that it induces an equivalence.

4.1 A comparison functor

Since a normed $\mathbb{E}_\infty$-ring is a priori less data than a C_p-$\mathbb{E}_\infty$-algebra, it is most natural to define a 'forgetful' functor from the latter to the former. In order to write down the functor, we need to unpack the definition of a C_2-$\mathbb{E}_\infty$-algebra.

Notation 4.1. Observe that $\mathrm{Span}\left(\mathrm{Fin}_{C_p}^{/V}\right)$ is 0-semiadditive [BH21, Lemma C.3] and define $\underline{\mathrm{Span}}(\mathrm{Fin}_{C_p,*})$ to be the colimit of the functor $V \mapsto \mathrm{Span}\left(\mathrm{Fin}_{C_p}^{/V}\right)$ [Lur09, Corollary 3.3.4.3]. Since 0-semiadditive ∞-categories are closed under all colimits [Har20, Corollary 5.4], $\underline{\mathrm{Span}}(\mathrm{Fin}_{C_p})$ is 0-semiadditive. Moreover, notice that there is an inclusion $\underline{\mathrm{Fin}}_{C_p,*} \subset \underline{\mathrm{Span}}(\mathrm{Fin}_{C_p})$.

Let $\delta : J \to \underline{\mathrm{Fin}}_{C_p,*}$ be a diagram. Under the equivalence of [Har20, Theorem 4.1; BH21, Lemma C.4] the diagram δ classifies a functor $\mathrm{Span}(J^{\sqcup}, \mathrm{fold}, \mathrm{all}) \to \underline{\mathrm{Span}}(\mathrm{Fin}_{C_p})$ which evidently restricts to

$$\iota_J \colon \mathrm{Fin}_* \times J \to \underline{\mathrm{Fin}}_{C_p,*}. \tag{4.2}$$

When $J = \Delta^0$ and δ is the inclusion of a single object $T \in \underline{\mathrm{Fin}}_{C_p,*}$, we write ι_T.

Consider the diagrams $\alpha_2, \alpha_3 \colon \mathcal{O}_{C_p} \to \underline{\mathrm{Fin}}_{C_p,*}$

$$\begin{array}{ccccc} C_p & = & C_p & \longrightarrow & C_p/C_p \\ \downarrow & & \downarrow & & \Vert \\ C_p/C_p & = & C_p/C_p & = & C_p/C_p \end{array} \qquad \begin{array}{ccccc} C_p^{\sqcup p} & = & C_p^{\sqcup p} & \xrightarrow{\nabla} & C_p \\ \downarrow{\scriptstyle\nabla} & & \downarrow{\scriptstyle\nabla} & & \Vert \\ C_p & = & C_p & = & C_p \end{array}$$

resp., where C_p acts on $C_p^{\sqcup p}$ by permuting the terms of the disjoint union. The preceding discussion shows that there are functors

$$\iota_{\alpha_i} := - \times \alpha_i \colon \mathrm{Fin}_* \times \mathcal{O}_{C_p} \to \underline{\mathrm{Fin}}_{C_p,*}. \tag{4.3}$$

By a similar discussion to that of Construction 3.1, the $\iota_{(-)}$ induce functors

$$\iota_J \colon C_p\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) \to \mathrm{Fun}\left(J, \mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)\right). \tag{4.4}$$

Construction 4.5. Recall that the category of C_p-$\mathbb{E}_\infty$-algebras $C_p\mathbb{E}_\infty\mathrm{Alg}$ is given by sections of the fibration $\left(\underline{\mathrm{Sp}}^{C_p}\right)^{\otimes}$ (Definition 2.32). By (4.4), restricting to certain subcategories of $\underline{\mathrm{Fin}}_{C_p,*}$ gives functors:

(a) $\gamma_1 \colon C_p\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) \to \mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)$ given by restriction along ι_T of (4.2) for $T = [C_p/C_p = C_p/C_p]$.

(b) $\gamma_4 \colon C_p\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) \to \mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) \times \mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)$ given by restriction along $\iota_T \times \iota_S$ of (4.2) for $T = [C_p \twoheadrightarrow C_p/C_p]$ and $S = [C_p/C_p = C_p/C_p]$.

(c) $\gamma_5 \colon C_p\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) \to \mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp})^{BC_p \times BC_p} \times \mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp})^{BC_p}$ given by restriction along $\iota_T \times \iota_S$ of (4.2) for $T = \left[C_p^{\sqcup p} \xrightarrow{\nabla} C_p\right]$ and $S = [C_p = C_p]$, resp. Note that in the former case, C_p acts by permuting the factors of $C_p^{\sqcup p} \simeq C_p \times C_p$ cyclically.

(d) $\gamma_2 \colon C_p\mathbb{E}_\infty\mathrm{Alg} \to \mathrm{Fun}\left(\mathcal{O}_{C_p}, \mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{C_p})\right)$ given by restriction along ι_{α_2} of (4.3).

(e) $\gamma_3 \colon C_p\mathbb{E}_\infty\mathrm{Alg} \to \mathrm{Fun}\left(\mathcal{O}_{C_p}, \mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{BC_p})\right)$ given by restriction along ι_{α_3} of (4.3).

Proposition 4.6. *The functors of Construction 4.5 are related in the following way:*

(a) There is an equivalence $m \circ \gamma_1^e \simeq \gamma_3$.

(b) There is an equivalence $\mathrm{ev}_{C_p} \times \mathrm{ev}_{C_p/C_p} \circ \gamma_3 \simeq \gamma_5$.

(c) There is an equivalence $(((-)^e)^{\otimes 2} \times (-)^e) \circ \gamma_1 \simeq \gamma_5$.

(d) There is an equivalence $\left(\mathrm{ev}_{C_p} \times \mathrm{ev}_{C_p/C_p}\right) \circ \gamma_2 \simeq \gamma_4$ *of functors* $C_p\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) \to \mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)^{\times 2}$.

(e) There is an equivalence $\left(N^{C_p} \times id\right) \circ \gamma_1 \simeq \gamma_4$ *of functors* $C_p\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) \to \mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)^{\times 2}$.

(f) There is a commutative diagram

$$\begin{array}{ccc} C_p\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) & \xrightarrow{\gamma_2} & \mathrm{Fun}\left(\mathcal{O}_{C_p}, \mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)\right) \\ & {\scriptstyle\gamma_3}\searrow \quad \swarrow{\scriptstyle(-)^e} & \\ & \mathrm{Fun}\left(\mathcal{O}_{C_p}, \mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{BC_p})\right) & \end{array}$$

Corollary 4.7. *There is a canonical functor*

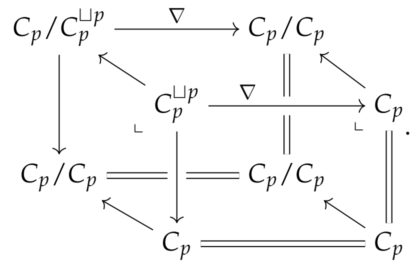
$$\gamma \colon C_p\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) \to N\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right).$$

Proof. The functors of Construction 4.5 may be regarded as

$$\gamma_i : C_p\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) \to \mathcal{N}(i)$$

where $\mathcal{N} : K \to \mathfrak{Cat}_\infty$ is as in Definition 3.11 and Notation 3.10. Proposition 4.6 shows that the functors γ_i commute with the structure maps in the diagram $\mathcal{N}$. By definition of a homotopy limit, the γ_i assemble to the desired functor γ. □

Proof of Proposition 4.6. (a) Consider the diagram $T := \mathcal{O}_{C_p} \times \Delta^1 \to \underline{\mathrm{Fin}}_{C_p,*}$



(4.8)

Note that $(m \circ \gamma_1)^e \simeq m \circ (\gamma_1^e)$. Now notice that $m \circ \gamma_1$ is given by restriction along $\iota_{\nabla_{C_p/C_p}}$ (i.e. the back face), while restriction along the front face implements γ_3. We may regard ι_T (Notation 4.1) as a natural transformation $\beta : (m \circ \gamma_1)^e \implies \gamma_3$ by (2.31). Since the morphisms from the back face to the front face of (4.8) are inert, β is a natural equivalence.

(b) This is evident.

(c) Follows from (a) and (b).

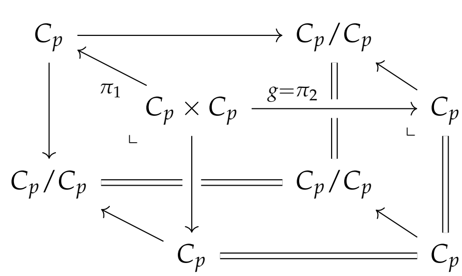
(d) This is evident from the definitions of α_2 and γ_4.

(e) Consider the morphism $w \colon \Delta^1 \to \underline{\mathrm{Fin}}_{C_p,*}$

$$\begin{array}{ccccc} C_p/C_p & \longleftarrow & C_p & = & C_p \\ \| & & \downarrow & & \downarrow \\ C_p/C_p & = & C_p/C_p & = & C_p/C_p \end{array}.$$

Notice that w is inert and recall that morphisms of operads take inert morphisms to inert morphisms. Because a morphism in $\left(\underline{\mathrm{Sp}}^{C_p}\right)^{\otimes}$ factors canonically as a p-cocartesian morphism and a fiberwise morphism, by definition of ζ (2.31) we see that restriction along ι_w gives an equivalence $N^{C_p}(\gamma_1^e) \simeq \pi_1\gamma_4$.

(f) Now consider the diagram $T := \mathcal{O}_{C_p} \times \Delta^1 \to \underline{\mathrm{Fin}}_{C_p,*}$



(4.9)

considered as an inert morphism (in fact, ev_1-cocartesian) from the back face α_2 (Notation 4.1) to the front face.

Identifying the underlying set of C_p with $\{0, 1, \ldots, p-1\}$, notice that the shear equivalence

$$\begin{aligned} sh\colon \{0,1,\ldots,p-1\} \times C_p &\to C_p \times C_p \\ (a,b) &\mapsto (a+b, b) \end{aligned}$$

which is equivariant with respect to the diagonal C_p-action on the target and the action by C_p on the second factor on the source. The shear map identifies g with the fold map $\nabla : C_p^{\sqcup p} \to C_p$, i.e. there is a commutative diagram

$$\begin{array}{ccc} C_p \times C_p & & \\ {\scriptstyle sh}\uparrow\wr & \searrow^{\pi_2 = g} & \\ & & C_p. \\ & \nearrow_{\pi_2 = \nabla} & \\ \{0,1,\ldots,p-1\} \times C_p & & \end{array}$$

Thus we see that the shear map induces an equivalence $\iota_g \simeq \iota_{\alpha_3} \simeq \gamma_3$.

Now restriction along ι_T (Notation 4.1) gives a natural transformation β

$$\begin{array}{ccc} & \nearrow^{\iota_{\alpha_2} \simeq \gamma_2} & \mathrm{Fun}\left(\mathcal{O}_{C_p}, \mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)\right) \\ C_p\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) & \Leftarrow_{\beta} & \downarrow (-)^e \\ & \searrow_{\iota_g} & \mathrm{Fun}\left(\mathcal{O}_{C_p}, \mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{BC_p}\right)\right) \end{array}.$$

Since the back-to-front arrows in (4.9) are inert, β is a natural equivalence. □

4.2 A parametrized monoidal envelope

To apply the Barr–Beck–Lurie theorem [Lur17, Proposition 4.7.3.22], we will need to show that γ of the free C_p-$\mathbb{E}_\infty$-algebra on an $\mathbb{E}_\infty$-algebra A computes the free normed algebra on A. A general strategy for understanding free C_p-$\mathbb{E}_\infty$ algebras is outlined in Remark 4.3.6 of [NS22]; we introduce the ingredients first, then outline the strategy in Recollection 4.13. Then we apply the aforementioned general strategy to exhibit a formula for the free C_p-$\mathbb{E}_\infty$-algebra on an $\mathbb{E}_\infty$-algebra A in Theorem 4.14.

Definition 4.10. [NS22, Definition 2.8.4 & Notation 2.8.3] Let $\mathcal{O}^\otimes$ be a $\mathcal{T}$-operad. let

$$\mathrm{Ar}^{act}_{\mathcal{T}}(\mathcal{O}^\otimes) := \mathcal{T}^{\mathrm{op}} \times_{\mathrm{Ar}(\mathcal{T}^{\mathrm{op}})} \mathrm{Ar}^{act}(\mathcal{O}^\otimes)$$

where $\mathrm{Ar}^{act}(\mathcal{O}^\otimes)$ is the $\mathcal{T}$-full subcategory on the active morphisms.

Suppose given a fibration of $\mathcal{T}$-operads $p\colon \mathcal{C}^\otimes \to \mathcal{O}^\otimes$. The *$\mathcal{O}$-monoidal envelope of $\mathcal{C}^\otimes$* is

$$\pi : \mathrm{Env}_{\mathcal{O},\mathcal{T}}(\mathcal{C})^\otimes := \mathcal{C}^\otimes \times_{\mathcal{O}^\otimes} \mathrm{Ar}^{act}_{\mathcal{T}}(\mathcal{O}^\otimes) \to \mathcal{O}^\otimes.$$

When $\mathcal{O} = \underline{\mathrm{Fin}}_{\mathcal{T},*}$ we drop it from notation.

Remark 4.11. More informally, an object of $\mathrm{Env}_{\mathcal{O},\mathcal{T}}(\mathcal{C})^{\otimes}$ is a pair $(c, g\colon p(c) \to o)$ where $c \in \mathcal{C}^{\otimes}$, $o \in \mathcal{O}^{\otimes}$, g is a fiberwise active arrow in $\mathcal{O}^{\otimes}$. The forgetful map π takes this tuple to o. By [NS22, Remark 2.8.5], the underlying $\mathcal{T}$-∞-category of $\mathrm{Env}_{\mathcal{O},\mathcal{T}}(\mathcal{C})^{\otimes}$ is $\mathrm{Env}_{\mathcal{O},\mathcal{T}}(\mathcal{C}) \simeq \mathrm{Com}^{\otimes}_{\mathcal{T}^{\simeq},act}$.

Proposition 4.12. *[NS22, Proposition 2.8.7] Let $p : \mathcal{C}^{\otimes} \to \mathcal{O}^{\otimes}$ be a fibration of $\mathcal{T}$-∞-operads, and let $\mathcal{D}^{\otimes} \to \mathcal{O}^{\otimes}$ be a cocartesian fibration of $\mathcal{T}$-∞-operads. Let $i : \mathcal{C}^{\otimes} \subseteq \mathrm{Env}_{\mathrm{Com}_{\mathcal{T}}}(\mathcal{C})^{\otimes}$ denote the inclusion of $\mathcal{C}^{\otimes}$ into its monoidal envelope. Then there is an adjunction*

$$i_! : \mathrm{Alg}_{\mathcal{O},\mathcal{T}}(\mathcal{C}, \mathcal{D}) \rightleftarrows \mathrm{Alg}_{\mathcal{O},\mathcal{T}}(\mathrm{Env}_{\mathcal{O},\mathcal{T}}(\mathcal{C})^{\otimes}, \mathcal{D}) : i^*$$

and $i_!$ has essential image the full subcategory of the right-hand side given by $\mathrm{Fun}^{\otimes}_{\mathcal{O},\mathcal{T}}(\mathrm{Env}_{\mathcal{O},\mathcal{T}}(\mathcal{C})^{\otimes}, \mathcal{D})$.

Recollection 4.13. Consider $\mathcal{O} = \underline{\mathrm{Fin}}_{\mathcal{T},*}$, $\mathcal{E} = \left(\underline{\mathrm{Sp}}^{C_2}\right)^{\otimes}$ (Notation 3.10), and $\mathcal{C} = \mathrm{Com}_{\mathcal{T}^{\simeq}}$ (Example 2.28) in Theorem 2.35. Then there is an adjunction

$$F : \mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{C_2}) \leftrightarrows C_2\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{C_2}) : G.$$

where G is from (2.34). By Remarks 2.8.5 & 4.3.6 of [NS22], the free C_2-$\mathbb{E}_\infty$-algebra $F(A)$ on an $\mathbb{E}_\infty$-algebra in Sp^{C_2} is computed by the C_2-left Kan extension of $i_!A^{\otimes}\colon \mathrm{Env}_{\mathcal{T}}(\mathrm{Com}_{\mathcal{T}^{\simeq}})^{\otimes} \to \underline{\mathrm{Sp}}^{C_2}$ along the structure map $\pi : \mathrm{Env}_{\mathcal{T}}(\mathrm{Com}_{\mathcal{T}^{\simeq}})^{\otimes} \to \mathrm{Com}^{\otimes}_{\mathcal{T}}$, where $i_!$ is from Proposition 4.12.

Theorem 4.14. *Let $A \in \mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)$ (also see Lemma 4.30) and consider the adjunction $F \dashv G$ of Recollection 4.13.*

(1) The underlying C_p-spectrum of the free C_p-$\mathbb{E}_\infty$ algebra $F(A)$ on A is given by (via the recollement of Proposition 2.15)

$$F(A) \simeq \begin{array}{ccc} & & A^{\varphi C_p} \otimes A^e_{hC_p} \\ & & \big\downarrow{\scriptstyle s_A \otimes \nu_A} \\ A^e & \longmapsto & A^{tC_p} \end{array} \tag{4.15}$$

where u is the unit, $s_A : A^{\varphi C_p} \to A^{tC_p}$ is the structure map, and ν_A is the twisted Tate-valued Frobenius (Definition 3.8).

(2) There is a canonical $\mathbb{E}_\infty$ ring map $\eta_A\colon A \to GF(A)$ given by $id_{A^{\varphi C_p}} \otimes (\eta_{A^e_{hC_p}} : \mathbb{S}^0 \to A^e_{hC_p})$ on geometric fixed points and the identity on underlying.

Proof. By Recollection 4.13, the C_p-$\mathbb{E}_\infty$-algebra $F(A)$ may be computed as the C_p-left Kan extension of $i_!A^{\otimes}\colon \mathrm{Env}_{\mathcal{T}}(\mathrm{Com}_{\mathcal{T}^{\simeq}})^{\otimes} \to \left(\underline{\mathrm{Sp}}^{C_2}\right)^{\otimes}$ along the structure map $\pi : \mathrm{Env}_{\mathcal{T}}(\mathrm{Com}_{\mathcal{T}^{\simeq}})^{\otimes} \to \mathrm{Com}^{\otimes}_{\mathcal{T}}$.

Denote $x = [C_p/C_p = C_p/C_p] \in \mathrm{Com}^{\otimes}_{\mathcal{T}}$. In particular, the C_p-spectrum underlying $F(A)$ may be computed as the C_p-left Kan extension of $i_!A^{\otimes}_{\underline{x}}\colon \left(\mathrm{Com}^{\otimes}_{\mathcal{T}^{\simeq},act}\right)_{\underline{x}} \to \underline{\mathrm{Sp}}^{C_p}$ along the structure map $\pi_{\underline{x}} : \left(\mathrm{Com}^{\otimes}_{\mathcal{T}^{\simeq},act}\right)_{\underline{x}} \simeq \mathrm{Env}_{\mathcal{T}}(\mathrm{Com}_{\mathcal{T}^{\simeq}})^{\otimes}_{\underline{x}} \to \left(\mathrm{Com}^{\otimes}_{\mathcal{T}}\right)_{\underline{x}} \simeq \mathcal{T}^{\mathrm{op}}$.

Let $I = \left(\mathrm{Com}^{\otimes}_{\mathcal{T}^{\simeq},act}\right)_{\underline{x}} \xrightarrow{q} \mathcal{T}^{\mathrm{op}}$ be shorthand for our indexing diagram and write I_{C_p} and I_{C_p/C_p} for the respective fibers (not parametrized fibers). We will write $F|_{C_p}$ for the restriction of a diagram F defined on I to I_{C_p}.

By definition of a C_2-left Kan extension and Definition 5.2 of [Sha18], we seek a $\mathcal{T}^{\mathrm{op}}$-initial lift

$$\begin{array}{ccc} & & \underline{\mathrm{Fun}}_{\mathcal{T}^{\mathrm{op}}}\left(I \star_{\mathcal{T}^{\mathrm{op}}} \mathcal{T}^{\mathrm{op}}, \underline{\mathrm{Sp}}^{C_p}\right) \\ & \overset{\widetilde{F(A)}}{\nearrow} & \downarrow \\ \mathcal{T}^{\mathrm{op}} & \xrightarrow[i_! A^{\otimes}_{\underline{x}}]{} & \underline{\mathrm{Fun}}_{\mathcal{T}^{\mathrm{op}}}\left(I, \underline{\mathrm{Sp}}^{C_p}\right) \end{array} \quad . \tag{4.16}$$

Informally, a lift $\widetilde{F(A)}$ of (4.16) is the data of

- a cocartesian section $F(A)\colon \mathcal{T}^{\mathrm{op}} \to \underline{\mathrm{Sp}}^{C_p}$
- a morphism β from $i_! A^{\otimes}_{\underline{x}}|_{C_p}$ to the constant I_{C_p}-indexed diagram at $F(A)(C_p)$ in Sp^{BC_p}
- a morphism α from $i_! A^{\otimes}_{\underline{x}}|_{C_p/C_p}$ to the constant I_{C_p/C_p}-indexed diagram at $F(A)(C_p/C_p)$ in Sp^{C_p}
- Choose a functor $R\colon I_{C_p/C_p} \to I_{C_p}$ classified by the map $C_p \twoheadrightarrow C_p/C_p$. Then we require the data of an equivalence $(\alpha)^e \simeq \beta \circ R$ of natural transformations.

Now notice that the diagram $i_! A^{\otimes}_{\underline{x}}|_{C_p}$ is defined on $\left(\mathrm{Com}^{\otimes}_{\mathcal{T}^{\simeq},act}\right)_{\underline{x},C_p}$, which has a final object $[C_p = C_p]$. Thus for $\widetilde{F(A)}(C_p)$ to be an initial object of the C_p-fiber of (4.16), we must have $F(A)^e \simeq A^e$. An initial object of the C_p/C_p-fiber of (4.16) is equivalently an object $F(A) : \mathcal{T}^{\mathrm{op}} \to \underline{\mathrm{Sp}}^{C_p}$ representing the functor

$$\begin{aligned} \underline{\mathrm{Sp}}^{C_p} &\to \mathrm{Spc} \\ B &\mapsto \hom_{\underline{\mathrm{Fun}}_{\mathcal{T}^{\mathrm{op}}}(I, \underline{\mathrm{Sp}}^{C_p})}\left(i_! A^{\otimes}_{\underline{x}}, q^* B\right). \end{aligned}$$

By a similar argument to our earlier discussion of morphisms in categories of cocartesian sections (Observation 3.19) and Proposition 2.15, the space of morphisms from the diagram $i_! A^{\otimes}_{\underline{x}}$ to $q^* B$ sits in a fiber sequence

$$
\begin{array}{c}
\mathrm{fib}\left(\hom_{\mathrm{Fun}\left(I|_{C_p/C_p}, Ar(\mathrm{Sp})\right)}\left(\begin{array}{cc} (i_! A^{\otimes}_{\underline{x}}|_{C_p/C_p})^{\varphi C_p} & (q^* B|_{C_p/C_p})^{\varphi C_p} \\ \downarrow & \downarrow \\ (i_! A^{\otimes}_{\underline{x}}|_{C_p/C_p})^{tC_p} & q^* B|^{tC_p}_{C_p/C_p} \end{array}\right) \to \hom_{\mathrm{Fun}\left(I|_{C_p}, \mathrm{Sp}\right)}\left((i_! A^{\otimes}_{\underline{x}}|_{C_p})^{tC_p}, q^* B|^{tC_p}_{C_p}\right)\right) \\
\downarrow \\
\hom_{\mathrm{Fun}_{\mathcal{T}^{op}}\left(I, \underline{\mathrm{Sp}}^{C_p}\right)}\left(i_! A^{\otimes}_{\underline{x}}, q^* B\right) \simeq \hom_{\mathrm{Fun}\left(I|_{C_p/C_p}, \underline{\mathrm{Sp}}^{C_p}\right)}\left(i_! A^{\otimes}_{\underline{x}}|_{C_p/C_p}, q^* B|_{C_p/C_p}\right) \\
\big\downarrow {\scriptstyle (-)^e} \\
\hom_{\mathrm{Fun}_{BC_p}\left(I|_{C_p}, \underline{\mathrm{Sp}}^{BC_p}\right)}\left(i_! A^{\otimes}_{\underline{x}}|_{C_p}, q^* B|_{C_p}\right)
\end{array}
.
$$

By the previous discussion, we have $\hom_{\mathrm{Fun}_{BC_p}\left(I|_{C_p}, \underline{\mathrm{Sp}}^{BC_p}\right)}(i_! A^{\otimes}_{\underline{x}}|_{C_p}, q^* B^e) \simeq \hom_{\mathrm{Sp}^{BC_p}}(A^e, B^e)$. Thus we see that for $\widetilde{F(A)}(C_p/C_p)$ to be an initial object of the C_p/C_p-fiber of (4.16), it suffices to take $F(A)^{\varphi C_p}$ to be the colimit of the diagram

$$(i_! A^{\otimes}_{\underline{x}})^{\varphi C_p} : \left(\mathrm{Com}^{\otimes}_{\mathcal{T}^{\simeq}, act}\right)_{\underline{x}, C_p/C_p} \to \mathrm{Sp}.$$

By Lemma 4.18, the C_p-left Kan extension of $i_! A^{\otimes}_{\underline{x}}$ along $\pi_{\underline{x}} : \mathrm{Env}(\mathrm{Com}_{\mathcal{T}^{\simeq}})_{\underline{x}} \to (\mathrm{Com}_{\mathcal{T}})_{\underline{x}}$ is computed on C_p geometric fixed points by (4.15).

The existence of the unit η_A follows from monadicity (Proposition 4.29), and its exact form follows from tracing through the definition of C_p-left Kan extension. □

Warning 4.17. The G-∞-category of G-spectra $\underline{\mathrm{Sp}}^G$ is *not* an example of the G-category of objects of Construction 2.6. Thus many of the techniques to compute G-left Kan extensions of [Sha18] do not apply to our proof of Theorem 4.14.

Lemma 4.18. *Consider the fiber* $\left(\mathrm{Com}^{\otimes}_{\mathcal{T}^{\simeq}}\right)_{act, C_p/C_p}$ *(not parametrized fiber) over* C_p/C_p *of* $\left(\mathrm{Com}^{\otimes}_{\mathcal{T}^{\simeq}}\right)_{act}$*. The inclusion*

$$\iota \colon BC_p \sqcup * \hookrightarrow \left(\mathrm{Com}^{\otimes}_{\mathcal{T}^{\simeq}}\right)_{act, C_p/C_p}$$

of the full subcategory spanned by the object

$$
\begin{array}{ccc}
C_p \sqcup C_p/C_p & \longrightarrow & C_p/C_p \\
\downarrow & & \| \\
C_p/C_p & = & C_p/C_p
\end{array}
$$

is cofinal.

Proof. Since we consider the fiber over C_p/C_p, the target is always C_p/C_p and we omit it throughout the following proof. Observe that there is a pullback diagram of simplicial sets

$$\begin{array}{ccc} BC_p \sqcup * & \xrightarrow{\iota} & (\mathrm{Com}^{\otimes}_{\mathcal{T}^{\simeq}})_{act,C_p/C_p} \\ \downarrow & & \downarrow Q \\ \{\langle 2\rangle, \langle 1\rangle, \{*,2\}\} & \longrightarrow & \mathrm{Sub} \end{array} .$$

By Lemma 4.21 and [Lur09, Proposition 4.1.2.15], Q is smooth. By Remark 4.1.2.10 of *loc. cit.* and Lemma 4.20, ι is cofinal. □

Recollection 4.19. Recall the category Sub of [Lur17, Definition 2.2.3.2] which was defined to have

(a) objects of Sub are triples $(\langle n\rangle, S, T)$ where $S, T \subseteq \langle n\rangle$ such that $S \cup T = \langle n\rangle$ and $S \cap T = \langle n\rangle$.

(b) a morphism of Sub from $(\langle n\rangle, S, T)$ to $(\langle n'\rangle, S', T')$ is a pointed map $f : \langle n\rangle \to \langle n'\rangle$ such that $f(S) \subseteq S'$ and $f(T) \subseteq T'$.

The ∞-category Sub is an ∞-operad by Proposition 2.2.3.5 of *loc. cit.* applied to $\mathcal{C}^{\otimes} = \mathcal{D}^{\otimes} = \mathrm{Fin}_*$. Write $\pi : \mathrm{Sub} \to \mathrm{Fin}_*$ for the structure map.

Lemma 4.20. *Let $\mathcal{A} \subseteq \mathrm{Env}_{\mathrm{Fin}_*}(\mathrm{Sub})$ denote the full subcategory on the object $(a, \pi(a) \to \langle 1\rangle)$ for $a = (\langle 2\rangle, \langle 1\rangle, \{2,*\})$. Then the inclusion*

$$\iota\colon \mathcal{A} \longrightarrow \mathrm{Env}_{\mathrm{Fin}_*}(\mathrm{Sub})$$

is cofinal.

Proof. We verify criterion (2) of [Lur09, Theorem 4.1.3.1]. Observe that for every object $(\langle n\rangle, S, T)$ of Sub, there is a unique morphism $(\langle n\rangle, S, T) \to (\langle 2\rangle, \langle 1\rangle, \{2,*\})$ which sends all $s \in S \setminus \{*\}$ to 1 and all $t \in T \setminus \{*\}$ to 2. □

Lemma 4.21. *There is a functor $Q\colon \mathrm{Com}_{\mathcal{O}^{\simeq}_{C_p}} \to \mathrm{Sub} \simeq \mathrm{Fin}_* \boxplus \mathrm{Fin}_*$ which takes a C_p-set T to its set of C_p-orbits grouped by orbit type, i.e. $Q : C_p \mapsto (\langle 1\rangle, \langle 1\rangle, \{*\})$ and $Q : C_p/C_p \mapsto (\langle 1\rangle, \{*\}, \langle 1\rangle)$. The functor Q is a coCartesian fibration classified by the functor*

$$\mathrm{Sub} \to \mathfrak{Cat}$$
$$(\langle n\rangle, S, T) \mapsto \bigsqcup_S BC_p \sqcup \bigsqcup_T * .$$

Construction 4.22. Let $A \in \mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{C_p})$. Given any $(B, n_B\colon N^{C_p}B \to B) \in N\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)$, there is a canonical map

$$f : \hom_{\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{C_p})}(A, B) \to \hom_{N\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{C_p})}(\gamma F(A), (B, n_B\colon N^{C_p}B \to B)).$$

By Observation 3.19 and Corollary 2.18, we may define f 'componentwise.' Denote $\hom_{\mathcal{N}(i)}(p_iF(A), p_i(B))$ by M_i (Definition 3.11). We have

$$M_0 = \hom_{\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{C_p})}(F(A), B) \simeq \hom_{\mathbb{E}_\infty\mathrm{Alg}}(A, B) \underset{\hom\left(A^{tC_p}, B^{tC_p}\right)}{\times} \hom\begin{pmatrix} A^e_{hC_p} & B^{\varphi C_p} \\ \downarrow & \downarrow \\ A^{tC_p}, & B^{tC_p} \end{pmatrix}.$$
$$=: M_0' \times_{M^t} M_0''$$

Take the identity on M_0' and define $\hom_{\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{C_p})}(A,B) \to M_0''$ to be the composite

$$f_0'' \colon \hom_{\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{C_p})}(A,B) \xrightarrow{N^{C_p}} \hom_{\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{C_p})}\left(N^{C_p}A, N^{C_p}B\right) \xrightarrow{g} M'$$

where g takes $h : N^{C_p}A \to N^{C_p}B$ to the outermost trapezoid in the commutative diagram

$$\begin{array}{ccccc}
A^e & \xrightarrow{\quad h \quad} & B^e & \xrightarrow{n_B^{\varphi C_p}} & B^{\varphi C_p} \\
\downarrow{\scriptstyle \Delta} & & \downarrow{\scriptstyle \Delta} & & \\
((A^e)^{\otimes p})^{tC_p} & \xrightarrow{(h^{\otimes p})^{tC_p}} & ((B^e)^{\otimes p})^{tC_p} & \xrightarrow{n_B^{tC_p}} & \downarrow \\
\downarrow{\scriptstyle m^{tC_p}} & & & & \\
A^{tC_p} & & \xrightarrow{\quad h^{tC_p} \quad} & & B^{tC_p}
\end{array}$$

where by definition $n_B^{tC_p} \simeq m_{B^e}^{tC_p}$ and the lower trapezoid is the Tate construction $(-)^{tC_p}$ on m of (3.2) applied to h. Clearly f_0' and f_0'' lift canonically to a functor $f_0 : \hom_{\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{C_p})}(A,B) \to M_0$.

Take $f_4 : \hom_{\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{C_p})}(A,B) \to M_4$ to be the product $N^{C_p}(-^e) \times \mathrm{id}$. The map f_4 clearly lifts to $f_2 : \hom_{\mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp}^{C_p})}(A,B) \to M_2$ and is identified canonically with $(N^{C_p}(-^e) \times \mathrm{id}) \circ f_0$. Since $F(A)^e \simeq A^e$, we may define f_3 and f_5 as $m_{(-)^e}$ and $(-^e)^{\otimes 2} \times (-)^e$, respectively.

The f_i assemble to give the desired map.

4.3 Proof of main theorem

Equipped with an explicit description of the free C_p-$\mathbb{E}_\infty$-algebra on an $\mathbb{E}_\infty$-algebra A in C_p-spectra from the previous section, here we show that γ of the free C_p-$\mathbb{E}_\infty$-algebra on an $\mathbb{E}_\infty$-algebra A computes the free normed algebra on A using our description of mapping spaces in the category of normed $\mathbb{E}_\infty$-algebras. The main result then follows from an application of the Barr–Beck–Lurie theorem.

Theorem 4.23. *The functor $\gamma \colon C_p\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) \to N\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)$ of Corollary 4.7 is an equivalence.*

Proof. Consider the diagram of forgetful functors

$$\begin{array}{ccc}
C_p\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) & \xrightarrow{\qquad \gamma \qquad} & N\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) \\
& {\scriptstyle G}\searrow \qquad \swarrow{\scriptstyle G'} & \\
& \mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) &
\end{array} \tag{4.24}$$

where G' is from Definition 3.11 and G is (2.34). The diagram (4.24) evidently commutes.

The functor G is monadic by Proposition 4.29. The functor G' is monadic by Proposition 3.21. Now for any $A \in \mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_2}\right)$, the unit $A \to \gamma F(A)$ of Theorem 4.14 induces an equivalence $F'(A) \simeq \gamma F(A)$ by Corollary 4.27. The result follows from [Lur17, Proposition 4.7.3.16]. □

Proposition 4.25. *Let A be an $\mathbb{E}_\infty$-ring in Sp^{C_p} and let $(B, n_B\colon N^{C_p}B \to B)$ be a normed $\mathbb{E}_\infty$-ring in Sp^{C_p}. Then precomposition with the $\mathbb{E}_\infty$-map $\eta_A : A \to GF(A)$ of Theorem 4.14 induces an equivalence of morphism spaces*

$$\begin{array}{c} Hom_{N\mathbb{E}_\infty}\Big(\big(\gamma F(A), n_{F(A)}\colon N^{C_p}\gamma F(A) \to \gamma F(A)\big), \big(B, n_B\colon N^{C_p}B \to B\big)\Big) \\ \big\downarrow G' \\ Hom_{\mathbb{E}_\infty}(G'\gamma F(A), G'(B)) \\ \big\downarrow \eta^* \\ Hom_{\mathbb{E}_\infty}(A, G'(B)). \end{array} \qquad \text{(the composite is marked } \wr\text{)} \tag{4.26}$$

where G' is the forgetful functor of Definition 3.11 and γ is the functor of Corollary 4.7. That is, $\eta_{(-)}$ is a unit for the functors $(\gamma \circ F, G')$ in the sense of [Lur09, Definition 5.2.2.7].

Corollary 4.27. *The natural transformation $\eta_{(-)}$ exhibits $\gamma \circ F$ as a left adjoint to G'.*

Proof. Follows from [Lur09, Proposition 5.2.2.8] and Proposition 4.25. □

Proof of Proposition 4.25. By Observation 3.19, the space of morphisms $\mathrm{Hom}_{N\mathbb{E}_\infty}((F(A), n_{F(A)}\colon N^{C_p}F(A) \to F(A)), (B, n_B\colon N^{C_p}B \to B))$ is computed by the limit of the diagram

$$\begin{array}{ccc}
 & \mathrm{hom}\left(\begin{array}{c} A^e \\ \downarrow \\ (A^{\otimes p})^{tC_p}\end{array}, \begin{array}{c} B^e \\ \downarrow \\ (B^{\otimes p})^{tC_p}\end{array}\right) & \longleftarrow \;\mathrm{hom}\left(\begin{array}{c} A \\ \downarrow\Delta \\ (A^{\otimes p})^{tC_p}\end{array}, \begin{array}{c} B \\ \downarrow\Delta \\ (B\otimes p)^{tC_p}\end{array}\right) \times \mathrm{hom}\left(\begin{array}{c} A \\ \downarrow\Delta \\ (A^{\otimes p})^{tC_p}\end{array}, \begin{array}{c} B^{\varphi C_p} \\ \downarrow\Delta \\ B^{tC_p}\end{array}\right) \mathrm{hom}\left(\begin{array}{c} A^{\varphi C_p}\otimes A_{hC_p} \\ \downarrow s_A\otimes \nu_A \\ A^{tC_p}\end{array}, \begin{array}{c} B^{\varphi C_p} \\ \downarrow\Delta \\ B^{tC_p}\end{array}\right). \\
 {\scriptstyle m\colon (-^e)^{\otimes p} \to (-^e)} \nearrow & \downarrow & \downarrow \\
 & \mathrm{hom}\left((A^{\otimes p})^{tC_p}, (B^{\otimes p})^{tC_p}\right) \times \mathrm{hom}\left(A^{tC_p}, B^{tC_p}\right) & \nwarrow \\
 \nearrow & & \\
\mathrm{hom}_{\mathbb{E}_\infty \mathrm{Alg}(\mathrm{Sp}^{C_p})}(F(A), B) & \longrightarrow & \mathrm{hom}\left(\begin{array}{c} A \\ \downarrow\Delta \\ (A^{\otimes p})^{tC_p}\end{array}, \begin{array}{c} B \\ \downarrow\Delta \\ (B^{\otimes p})^{tC_p}\end{array}\right) \times \mathrm{hom}\left(\begin{array}{c} A^{\varphi C_p}\otimes A_{hC_p} \\ \downarrow\Delta \\ A^{tC_p}\end{array}, \begin{array}{c} B^{\varphi C_p} \\ \downarrow\Delta \\ B^{tC_p}\end{array}\right)
\end{array} \tag{4.28}$$

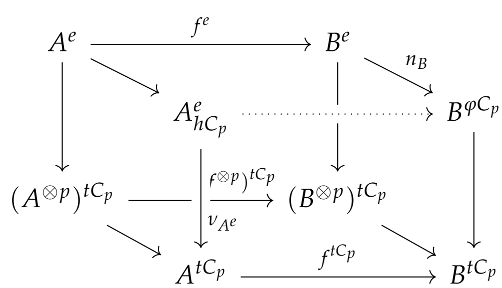
where all morphisms are computed in either $\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{BC_p}\right)$ or $\mathrm{Ar}\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{BC_p}\right)$. Notice that

$$\hom_{\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)}(F(A),B) \simeq \hom_{\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)}(A,B) \underset{\hom\left(A^{tC_p},B^{tC_p}\right)}{\times} \hom\begin{pmatrix} A_{hC_p}, & B^{\varphi C_p} \\ \downarrow \nu_A & \downarrow \Delta \\ A^{tC_p} & B^{tC_p}\end{pmatrix}$$

and moreover the composite

$$\hom_{N\mathbb{E}_\infty\mathrm{Alg}}(F(A),B) \xrightarrow{G'} \hom_{\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)}(F(A),B) \xrightarrow{\pi_1} \hom_{\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)}(A,B)$$

is equivalent to $\eta^* \circ G'$. Unravelling definitions, we see that given a point $f \in \hom_{\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)}(A,B)$, the fiber of $\eta^* \circ G'$ over f is given by the space of fillings of the below diagram to a commutative diagram $\mathcal{O}_{C_p} \times (\Delta^1)^{\times 2} \to \mathbb{E}_\infty\mathrm{Alg}(\mathrm{Sp})$:



wherein all but the top and front face are given. This space is contractible by the adjunction

$$(-)^{\mathrm{triv}} \colon \mathrm{Sp} \leftrightarrows \mathrm{Sp}^{C_p} \colon (-)_{hC_p}.$$

Now by Construction 4.22, $\eta^* \circ G'$ admits a right inverse f, hence it is surjective on connected components. Thus the result follows. □

Proposition 4.29. *The forgetful functor $G : C_p\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) \to \mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right)$ of (2.34) is monadic.*

Proof. We consider the commuting triangle of forgetful functors

$$\begin{array}{ccc} C_p\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) & \xrightarrow{G} & \mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) \\ & \searrow \quad \swarrow & \\ & \mathrm{Sp}^{C_p} & \end{array}.$$

The upper horizontal arrow is given by restricting along the C_p operadic inclusion $\mathrm{Com}^{\otimes}_{\mathcal{T}^{\simeq}} \hookrightarrow \mathrm{Com}^{\otimes}_{\mathcal{T}}$ and applying the equivalence of Lemma 4.30. By [NS22, Corollary 5.1.5], the diagonal arrows are monadic; in particular by the Barr–Beck–Lurie theorem the right diagonal arrow is conservative. By [NS22, Theorem 4.3.4] applied to the morphism $\mathrm{Com}^{\otimes}_{\mathcal{T}^{\simeq}} \hookrightarrow \mathrm{Com}^{\otimes}_{\mathcal{T}}$, the upper horizontal arrow admits a left adjoint. Thus the result follows from [Lur17, Proposition 4.7.3.22.]. □

Lemma 4.30. *For the minimal indexing system $\mathrm{Com}_{\mathcal{T}^{\simeq}}$ (Example 2.28), we have a canonical identification of $\mathrm{Com}_{\mathcal{T}^{\simeq}}$-algebras in $\left(\underline{\mathrm{Sp}}^{C_p}\right)^{\otimes}$ with $\mathcal{O}_{C_p}^{op}$-families of $\mathbb{E}_\infty$-algebras in spectra, or equivalently $\mathbb{E}_\infty$-algebras in Sp^{C_p}.*

Proof. Compare [NS22, Corollary 2.4.15] and [Lur17, Example 2.1.3.5].

Let $A : \mathrm{Com}^{\otimes}_{\mathcal{T}^{\simeq}} \to \mathcal{C}^{\otimes}$ be a section of $p : \mathcal{C}^{\otimes} \to \underline{\mathrm{Fin}}_{\mathcal{T},*}$. Notice that A is a $\mathrm{Com}_{\mathcal{T}^{\simeq}}$-algebra if and only if A is $\mathcal{T}$-right Kan extended from the full subcategory of $\mathrm{Com}^{\otimes}_{\mathcal{T}^{\simeq}}$ spanned by coproducts of $[C_p/C_p = C_p/C_p]$. The result follows from [Lur17, Proposition 4.3.2.15]. □

5 Applications & examples

5.1 Examples

The example which will be used in the author's upcoming work on real (C_2-equivariant) trace theories is

Theorem 5.1. *Let k be a discrete commutative ring. The constant C_p-Mackey functor $\underline{k}$ on k uniquely acquires the structure of a C_p-$\mathbb{E}_\infty$-ring.*

Proof. In view of Theorem 4.23, it suffices to show that $\underline{k}$ can be lifted to an object of Definition 3.11. Note that the isotropy separation sequence for $\underline{k}$ is

$$\begin{array}{ccc} k^{C_p} & \longrightarrow & \underline{k}^{\varphi C_p} \\ {\scriptstyle \tau_{\geq 0}}\downarrow & & \downarrow \\ k^{hC_p} & \longrightarrow & k^{tC_p} \end{array} .$$

The left vertical arrow is a connective cover; hence so is the right vertical arrow and $\underline{k}^{\varphi C_p} = \tau_{\geq 0} k^{tC_p}$. Note that $\tau_{\geq 0} k^{tC_p}$ is an $\mathbb{E}_\infty$-ring in spectra because the Tate construction and connective cover are lax symmetric monoidal functors. By Theorem 4.23 and Remark 3.17, it suffices to exhibit a commutative diagram

$$\begin{array}{ccc} k & \overset{n_{\underline{k}}}{\dashrightarrow} & \underline{k}^{\varphi C_p} \\ {\scriptstyle \text{Tate diagonal}}\downarrow & & \downarrow{\scriptstyle \alpha} \\ (k^{\otimes p})^{tC_p} & \xrightarrow{m^{tC_p}} & k^{tC_p} \end{array} .$$

The dotted arrow and 2-cell making the diagram commute exist up to contractible choice because the inclusion of connective $\mathbb{E}_\infty$-algebra spectra into all $\mathbb{E}_\infty$-algebra spectra admits a right adjoint [Lur17, Proposition 7.1.3.13], and our assumption that k is connective. □

There is a natural class of equivariant C_p-spectra for which the data of (3.18) is no extra data at all.

Recollection 5.2. The ∞-category $\mathrm{Sp}^{C_p,\mathrm{Borel}}$ of *Borel C_p*-spectra is the image of Sp^{BC_p} under the fully faithful right adjoint to the 'underlying' spectrum functor of Proposition 2.15. Write $C_p\mathbb{E}_\infty\mathrm{Alg}^{\mathrm{Borel}}\left(\mathrm{Sp}^{C_p}\right)$

for the pullback

$$C_p\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) \underset{\mathrm{Sp}^{C_p}}{\times} \mathrm{Sp}^{C_p,\mathrm{Borel}}.$$

In words, this is the category of C_p-$\mathbb{E}_\infty$-algebras whose underlying C_p-spectrum is Borel. A C_p-spectrum is Borel if and only if the structure map $A^{\varphi C_p} \to A^{tC_p}$ is an equivalence.

In view of the expected correspondence between the theories of N_∞-algebras of Blumberg–Hill and the C_p-$\mathbb{E}_\infty$-algebras of Nardin–Shah, we have the following analogue of [BH15, Theorem 6.26].

Proposition 5.3. *Every Borel $\mathbb{E}_\infty$-algebra in C_p-spectra admits an essentially unique structure of a $C_p\mathbb{E}_\infty$-algebra. More precisely, there is an equivalence of categories*

$$\mathbb{E}_\infty\mathrm{Alg}^{\mathrm{Borel}}\left(\mathrm{Sp}^{C_p}\right) \xrightarrow{\exists} C_p\mathbb{E}_\infty\mathrm{Alg}^{\mathrm{Borel}}\left(\mathrm{Sp}^{C_p}\right)$$

with inverse the forgetful functor G (2.34).

This result may also be regarded as a special case of [Hil22, Proposition 3.3.6].

Proof. Let $A \in \mathbb{E}_\infty\mathrm{Alg}^{\mathrm{Borel}}\left(\mathrm{Sp}^{C_p}\right)$. Then by Theorem 4.23, it suffices to produce a lift

$$\begin{array}{ccc} A^e & \overset{\exists ?}{\dashrightarrow} & A^{\varphi C_p} \\ \downarrow{\scriptstyle \Delta} & & \downarrow{\scriptstyle s_A} \\ (A^{\otimes p})^{tC_p} & \xrightarrow{m^{tC_p}} & A^{tC_p} \end{array}$$

which is functorial in A. By definition of Borel spectra, s_A is an equivalence, so the space of choices of $\dashrightarrow$ and a 2-cell making the diagram commute is contractible. ☐

Corollary 5.4. *The real bordism spectrum $MU_\mathbb{R}$ admits a unique refinement to C_2-$\mathbb{E}_\infty$-algebra.*

Proof. Follows from [HK01, Theorem 4.1(1)] and Proposition 5.3. ☐

Proposition 5.5. *Let $B \in \mathbb{E}_\infty\mathrm{Alg}\,(\mathrm{Sp})$ be an $\mathbb{E}_\infty$-algebra. Then $N^{C_p}B$ admits a canonical structure of a C_p-$\mathbb{E}_\infty$-algebra. That is, there is a factorization*

$$\begin{array}{ccc} & \overset{\exists}{\nearrow} & N\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) \\ & & \downarrow{\scriptstyle G'} \\ \mathbb{E}_\infty\mathrm{Alg}\,(\mathrm{Sp}) & \xrightarrow{N^{C_p}} & \mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_p}\right) \end{array}.$$

Proof. Then by Theorem 4.23, it suffices to produce a dotted arrow and a commutative diagram $\mathcal{O}_{C_p} \times \Delta^1 \to \mathbb{E}_\infty\mathrm{Alg}\,(\mathrm{Sp})$

$$\begin{array}{ccc} B^{\otimes p} & \overset{\exists ?}{\dashrightarrow} & B \\ {\scriptstyle \Delta}\downarrow & & \downarrow{\scriptstyle \Delta} \\ \left(B^{\otimes p^2}\right)^{tC_p} & \xrightarrow{m^{tC_2}} & (B^{\otimes p})^{tC_p} \end{array}$$

which is functorial in B. We can choose the dotted arrow to be m_B and a commutative diagram to be functorial in B because the Tate diagonal is functorial. ☐

5.2 Real motivic invariants

Here, we briefly recall that algebras with C_2-actions naturally give rise to motivic invariants valued in genuine C_2-spectra. These real motivic invariants and their associated real trace theories provided the impetus for this work.

We only provide brief sketches of the required constructions and definitions; readers who are unfamiliar with the following notions should refer to sources cited below for details.

Recollection 5.6 (Real topological K-theory)**.** [Ati66; Dug05] The space $\mathbb{Z} \times BU$ has a C_2-action coming from complex conjugation on the unitary group U, with C_2-fixed points $\mathbb{Z} \times BO$. Furthermore, there is a C_2-equivariant form of Bott periodicity $\mathbb{Z} \times BU \simeq \Omega^{\rho}(\mathbb{Z} \times BU)$. Real K-theory $KU_{\mathbb{R}}$ is the associated C_2-spectrum (under the equivalence in [GM17, §3]).

By Appendix A (see discussion after Theorem A.5) of [LN14], $KU_{\mathbb{R}}$ is an $\mathbb{E}_\infty$ algebra in C_2-spectra.

Recollection 5.7 (Poincaré ∞-categories)**.** There is an ∞-category $\mathcal{C}\mathrm{at}_\infty^p$ of *Poincaré ∞-categories* ([Cal+20a, Definitions 1.2.7-8]) whose objects are pairs $(\mathcal{C}, \Omega)$ consisting of a small stable ∞-category and a quadratic functor $\Omega : \mathcal{C}^{\mathrm{op}} \to \mathrm{Sp}$, and morphisms are given by duality-preserving exact functors. Moreover, the ∞-category $\mathcal{C}\mathrm{at}_\infty^p$ has a symmetric monoidal structure [Cal+20a, Theorem 5.2.7(iii)] lifting the Lurie tensor product on small stable ∞-categories.

Definition 5.8 (Real algebraic K-theory)**.** Let A be a C_2-$\mathbb{E}_\infty$-algebra. We may associate to A the module with genuine involution $(M = A^e, N = A^{\varphi C_2}, s_A : A^{\varphi C_2} \to A^{tC_2})$ (Definition 3.2.2 of *loc. cit*. To such a module with genuine involution there is an associated Poincaré ∞-category $\left(\mathcal{P}\mathrm{erf}_{A^e}, \Omega^{s_A}_{A^e}\right)$ ([Cal+20a, Construction 3.2.5]). The *real algebraic K-theory* $K_{\mathbb{R}}(A)$ of A is the real algebraic K-theory

$$K_{\mathbb{R}}(A) \simeq \mathrm{GW}^{\mathrm{ghyp}}\left(\mathcal{P}\mathrm{erf}_{A^e}, \Omega^{s_A}_{A^e}\right) \in \mathrm{Sp}^{C_2}$$

in the sense of [Cal+20b, Definition 4.5.1].

Proposition 5.9. *(1) The assignment $A \mapsto \left(\mathcal{P}\mathrm{erf}_{A^e}, \Omega^{s_A}_{A^e}\right)$ of Definition 5.8 (compare examples from §3.2, in particular Example 3.2.11 of [Cal+20a]) promotes to a symmetric monoidal functor*

$$C_2\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_2}\right) \to \mathcal{C}\mathrm{at}_\infty^p.$$

(2) The real algebraic K-theory of a C_2-$\mathbb{E}_\infty$-algebra R canonically refines to an $\mathbb{E}_\infty$-algebra in C_2-spectra.

Proof. To prove (1), it suffices to observe that a morphism of C_2-$\mathbb{E}_\infty$-algebras $\phi\colon A \to B$ induces a canonical triple (δ, γ, σ) in the sense of Corollary 3.3.2 of [Cal+20a] (corresponding to a hermitian functor $\left(\mathcal{P}\mathrm{erf}_{A^e}, \Omega^{s_A}_{A^e}\right) \to \left(\mathcal{P}\mathrm{erf}_{B^e}, \Omega^{s_B}_{B^e}\right)$covering the induction $\phi_*\colon \mathrm{Mod}_{A^e} \to \mathrm{Mod}_{B^e}$). Furthermore, the triple (δ, γ, σ) automatically satisfies the criterion of Lemma 3.3.3 & Definition 3.3.4 of *loc.cit.*, hence the associated hermitian functor is in fact Poincaré.

To prove (2), it suffices to exhibit a composite functor $C_2\mathbb{E}_\infty\mathrm{Alg}\left(\mathrm{Sp}^{C_2}\right) \to \mathcal{C}\mathrm{at}_\infty^p \to \mathrm{Sp}^{C_2}$ which is lax symmetric monoidal. The former functor is lax symmetric monoidal by (1). The latter functor is that of [Cal+20b, Definition 4.5.1]. That it is lax symmetric monoidal will appear in [Cal+]. □

A ring R is said to satisfy the *homotopy limit problem* if its genuine symmetric real K-theory is a Borel C_2-spectrum [Tho83; Cal+21, §3].

Corollary 5.10.
- *Real topological K-theory $KU_{\mathbb{R}}$ admits a unique refinement to a C_2-$\mathbb{E}_\infty$ ring spectrum.*
- *If A satisfies the* homotopy limit problem*, then $K_{\mathbb{R}}(A)$ admits a unique refinement to a C_2-$\mathbb{E}_\infty$ ring spectrum.*

Proof. By [Ati66] (also see [Rog08, proof of Proposition 5.3.1; Dug05, Corollary 7.6]), $KU_{\mathbb{R}}$ is Borel. Both results follow from Proposition 5.3. □

5.3 A relative enhancement

In this section we state a version of our main theorem *relative* to an arbitrary base C_p-$\mathbb{E}_\infty$-algebra A (Example 2.33). In order to make sense of a C_p-$\mathbb{E}_\infty$-algebra over A, we require a C_p-symmetric monoidal structure on the category of A-modules. That this is possible is suggested by the following

Definition 5.11. Let A be a C_p-$\mathbb{E}_\infty$-ring in Sp^{C_p}. The *(A-linear or relative) norm* is the functor

$$\underline{N}_e^{C_p}\colon \mathrm{Mod}_{A^e} \to \mathrm{Mod}_A\left(\mathrm{Sp}^{C_p}\right)$$
$$M \mapsto A \otimes_{N_e^{C_p}(A^e)} N_e^{C_p} M$$

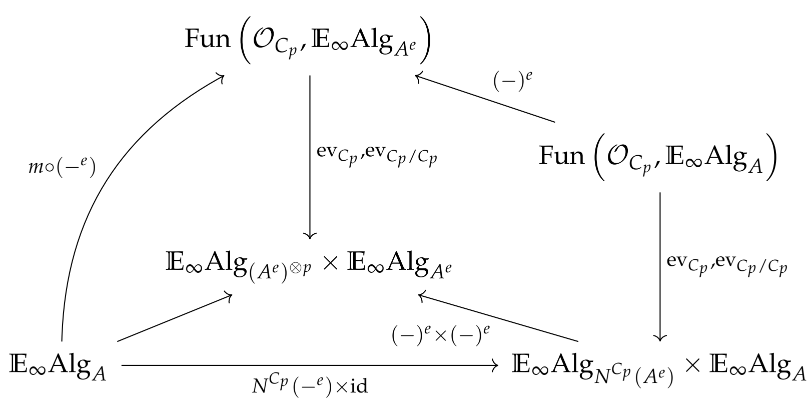
Note that the reasoning of Lemma 2.22 applies to show that $\underline{N}_e^{C_p}$ lifts to a colimit-preserving functor $\mathbb{E}_\infty\mathrm{Alg}_{A^e} \to \mathbb{E}_\infty\mathrm{Alg}_A$.

By Proposition A.9 (communicated by Jay Shah), we may regard the category of A-modules as a C_p-symmetric monoidal ∞-category.

Definition 5.12. Let A be a C_p-$\mathbb{E}_\infty$-algebra (Example 2.33). The ∞-category of C_p-$\mathbb{E}_\infty$-A-algebras is $\mathrm{Alg}_{\underline{\mathrm{Fin}}_{C_p,*}}\left(\underline{\mathrm{Fin}}_{C_p,*}, (\underline{\mathrm{Mod}}_A)^{\otimes}\right) =: C_p\mathbb{E}_\infty\mathrm{Alg}_A$ (Definition 2.32). In other words, it is the category of sections of $\underline{\mathrm{Mod}}_A^{\otimes} \to \underline{\mathrm{Fin}}_{C_p,*}$ which take inert morphisms to inert morphisms.

There is moreover a relative notion of normed algebras over A.

Definition 5.13. Let A be a C_p-$\mathbb{E}_\infty$-ring. We define the category $N\mathbb{E}_\infty\mathrm{Alg}_A$ of *normed $\mathbb{E}_\infty$-A-algebras* to be the limit of the diagram



where we have abbreviated $\mathbb{E}_\infty\mathrm{Alg}_A = \mathbb{E}_\infty\mathrm{Alg}_A\left(\mathrm{Sp}^{C_p}\right)$, $\mathbb{E}_\infty\mathrm{Alg}_{(A^e)^{\otimes p}} = \mathbb{E}_\infty\mathrm{Alg}_{(A^e)^{\otimes p}}\left(\mathrm{Sp}^{BC_p\times BC_p}\right)$, etc.

There is a relative version of the main results of this paper.

Proposition 5.14. *Let A be a C_p-$\mathbb{E}_\infty$-ring. There is a canonical forgetful functor*

$$\gamma_A\colon C_p\mathbb{E}_\infty\mathrm{Alg}_A \to N\mathbb{E}_\infty\mathrm{Alg}_A$$

Proof. Proceeds as in proof of Corollary 4.7. □

Theorem 5.15. *Let A be a C_p-$\mathbb{E}_\infty$-ring. Then the canonical comparison functor γ_A of Proposition 5.14 is an equivalence.*

Proof. Proceeds as in proof of Theorem 4.23. □

A Modules over normed equivariant algebras

In this appendix, we show that the category of modules over a C_p-$\mathbb{E}_\infty$-ring naturally acquires a structure of a C_p-symmetric monoidal ∞-category in the sense of Nardin–Shah via a relative norm (cf. Definition 5.11). The author would like to thank Jay Shah who communicated details of this construction.

Fix κ a regular cardinal and let $\mathcal{K}$ denote the collection of κ-small simplicial sets.

Recollection A.1. [Lur17, Notation 4.8.3.5.] Write $\mathrm{Alg}_{\mathbb{E}_1}(\mathcal{C}\mathrm{at}_\infty)$. It has objects given by monoidal ∞-categories which are compatible with κ-indexed colimits and whose morphisms are monoidal functors $F:\mathcal{C}^\otimes \to \mathcal{D}^\otimes$ whose preserve κ-indexed colimits. Write $U\colon \mathrm{Alg}_{\mathbb{E}_1}(\mathcal{C}\mathrm{at}_\infty) \to \mathcal{C}\mathrm{at}_\infty$ for the forgetful functor which forgets the monoidal structure.

[Lur17, Definition 4.8.3.7.] There is an ∞-category $\mathcal{C}\mathrm{at}_\infty^{\mathrm{Alg}}(\mathcal{K})$. Informally its objects are given by pairs $(\mathcal{C}^\otimes, A)$ where $\mathcal{C}$ is a monoidal ∞-category and A is an algebra object of $\mathcal{C}$. Morphisms from $(\mathcal{C}^\otimes, A)$ to $(\mathcal{D}^\otimes, B)$ are given by monoidal functors $F:\mathcal{C}\to\mathcal{D}$ such that $F(A)\simeq B$.

Similarly, there is an ∞-category $\mathcal{C}\mathrm{at}_\infty^{\mathrm{Mod}}(\mathcal{K})$ whose objects are pairs $(\mathcal{C}^\otimes,\mathcal{M})$ where $\mathcal{C}$ is a monoidal ∞-category and $\mathcal{M}$ is an ∞-category left tensored over $\mathcal{C}$. In particular, there is a forgetful functor

$$\begin{aligned}\Upsilon\colon \mathcal{C}\mathrm{at}_\infty^{\mathrm{Mod}}(\mathcal{K}) &\to \mathcal{C}\mathrm{at}_\infty \\ (\mathcal{C}^\otimes,\mathcal{M}) &\mapsto \mathcal{M}\end{aligned}. \tag{A.2}$$

[Lur17, Construction 4.8.3.24] There is a functor Θ making the following diagram commute:

$$\begin{array}{ccc}\mathcal{C}\mathrm{at}_\infty^{\mathrm{Alg}}(\mathcal{K}) & \xrightarrow{\Theta:(\mathcal{C}^\otimes,A)\mapsto(\mathcal{C}^\otimes,\mathrm{Mod}_A(\mathcal{C}))} & \mathcal{C}\mathrm{at}_\infty^{\mathrm{Mod}}(\mathcal{K}) \\ & {\scriptstyle u_a}\searrow \quad \swarrow{\scriptstyle u_m} & \\ & \mathrm{Alg}_{\mathbb{E}_1}(\mathcal{C}\mathrm{at}_\infty) & \end{array} \tag{A.3}$$

where the vertical arrows are the universal fibrations classifying families of $\mathbb{E}_1$-algebras in $\mathcal{C}$ and modules over said algebras in $\mathcal{C}$, respectively [Lur17, Remarks 4.8.3.8. & 4.8.3.20.].

Notation A.4. Hereafter, we drop $\kappa, \mathcal{K}$ from notation.

Lemma A.5. *Let A be a C_p-$\mathbb{E}_\infty$-algebra object of $\left(\underline{\mathrm{Sp}}^{C_p}\right)^{\otimes}$, and recall the functor $\zeta \colon \mathrm{Span}(\mathrm{Fin}_{C_p}) \to \mathrm{Alg}_{\mathbb{E}_1}(\mathcal{C}\mathrm{at})$ of Recollection 2.30. Then A lifts to a cocartesian section $\tilde{A}$ of $\int \zeta$.*

Proof. Let $T \to C_p/H$ be an object of $\underline{\mathrm{Fin}}_{C_p,*}$. There is a natural functor $\iota_T := - \times T \colon \mathrm{Fin}_* \to \underline{\mathrm{Fin}}_{C_p,*}$. Moreover, $\iota_{(-)}$ assembles to give the functor

$$\begin{aligned} \iota \colon \mathrm{Fin}_* \times \underline{\mathrm{Fin}}_{C_p,*} &\to \underline{\mathrm{Fin}}_{C_p,*} \\ (S, T \to C_p/H) &\mapsto S \times T \to C_p/H \end{aligned}.$$

Consider the restriction $\iota_T^* A$ of A along ι_T. We may further precompose $\iota_T^* A$ with the structure morphism $\mathrm{Assoc}^{\otimes} \to \mathrm{Fin}_*$ where $\mathrm{Assoc}^{\otimes}$ is the $\mathbb{E}_1$ operad of [Lur17, Definition 4.1.1.3]. Then by the characterization of inert morphisms of Theorem 2.3.3 of [NS22], $\iota_T^* A$ and by definition of morphisms of operads (both parametrized and non-parametrized), $\iota_T^* A$ defines an associative algebra object in $\zeta(T)$. Likewise $\iota^* A$ defines a $\underline{\mathrm{Fin}}_{C_p,*}$-family of associative algebra objects, hence the existence of $\tilde{A}$ follows by the universal property characterizing $\mathcal{C}\mathrm{at}_\infty^{\mathrm{Alg}}$. ◻

Variant A.6. Let $\mathcal{K}_0$ denote the full subcategory of the arrow category $\mathrm{Ar}(\mathrm{Fin}_*)$ on those arrows given by the inclusion of the basepoint $\{*\} \hookrightarrow S$. There is a variant functor

$$\begin{aligned} \iota_\eta \colon \mathcal{K}_0 \times \underline{\mathrm{Fin}}_{C_p,*} &\to \underline{\mathrm{Fin}}_{C_p,*} \\ (\{*\} \hookrightarrow S, T) &\mapsto (\{*\} \hookrightarrow S) \times T \end{aligned}$$

which defines a $\Delta^1 \times \underline{\mathrm{Fin}}_{C_p,*}$-family of associative algebra objects.

Now consider the commutative diagram

$$\begin{array}{ccccccc} \int \zeta & \xrightarrow{u_a^*(\zeta)} & \mathcal{C}\mathrm{at}_\infty^{\mathrm{Alg}} & \xrightarrow{\Theta} & \mathcal{C}\mathrm{at}_\infty^{\mathrm{Mod}} & \xrightarrow{\Upsilon} & \mathcal{C}\mathrm{at}_\infty \\ {\scriptstyle \tilde{A}}\uparrow\downarrow & & \downarrow{\scriptstyle u_a} & & \downarrow{\scriptstyle u_m} & & \\ \underline{\mathrm{Fin}}_{C_p,*} & \xrightarrow{\zeta} & \mathrm{Alg}_{\mathbb{E}_1}(\mathcal{C}\mathrm{at}) & = & \mathrm{Alg}_{\mathbb{E}_1}(\mathcal{C}\mathrm{at}) & & \end{array}$$

where $\tilde{A}$ exists by Lemma A.5 and the center square is (A.3).

Definition A.7. Let A be a C_p-$\mathbb{E}_\infty$-algebra in C_p-spectra. Recall the Grothendieck construction [Lur09, Theorem 2.2.1.2]. Let $\underline{\mathrm{Mod}}_A^{\otimes}$ be the C_p-symmetric monoidal ∞-category classified by the morphism $\Upsilon \circ \Theta \circ u_a^*(\zeta) \circ \tilde{A}$. Let $\underline{\mathrm{Mod}}_A$ denote the corresponding underlying C_p-∞-category of $\underline{\mathrm{Mod}}_A^{\otimes}$.

Examples A.8.

(1) When $A = \mathbb{S}^0$, we recover $\underline{\mathrm{Mod}}_A \simeq \underline{\mathrm{Sp}}^{C_p}$.

(2) Suppose A is a C_p-$\mathbb{E}_\infty$-ring. Then $\underline{\mathrm{Mod}}_A$ may be regarded as the $\mathcal{O}_{C_p}$-diagram *of stable ∞-categories*

$$\mathrm{Mod}_A\left(\mathrm{Sp}^{C_p}\right) \xrightarrow{(-)^e} \mathrm{Mod}_{A^e}(\mathrm{Sp}) \circlearrowleft_{\sigma_*}.$$

The morphism $[C_p \to C_p/C_p] \to [C_p/C_p = C_p/C_p]$ in $\underline{\mathrm{Fin}}_{C_p,*}$ classifies the relative norm $\underline{N}^{C_p}$ of Definition 5.11.

The previous discussion shows that

Proposition A.9. *Let A be a C_p-$\mathbb{E}_\infty$-algebra in C_p-spectra. Then the C_p-∞-category of Definition A.7 naturally acquires a C_p-symmetric monoidal structure in the sense of [NS22, Definition 2.2.1].*

Remark A.10. By the proof of Lemma A.5, each A_T for $T \to C_p/H$ an object of $\underline{\mathrm{Fin}}_{C_p,*}$ is in fact an $\mathbb{E}_\infty$-algebra in $\zeta(T)$. Thus we write modules instead of left modules [Lur17, Corollary 4.5.1.6].

Construction A.11 (Parametrized base change)**.** Since $\underline{\mathrm{Fin}}_{C_p,*}$ is unital, the category of C_p-$\mathbb{E}_\infty$-algebras in C_p-spectra has an initial object $\underline{\mathbb{1}}$ [NS22, Definition 5.2.1 & Theorem 5.2.11, resp.] given fiberwise by the sphere spectrum. As in Lemma A.5, $\underline{\mathbb{1}}$ lifts to a coCartesian section $\tilde{\underline{\mathbb{1}}}$ of $\int \zeta$. Suppose A is a C_p-$\mathbb{E}_\infty$-ring spectrum. Variant A.6 shows that the unit map $\eta\colon \underline{\mathbb{1}} \to A$ induces a natural transformation $\tilde{\eta}\colon \tilde{\underline{\mathbb{1}}} \to \tilde{A}$. Under the Grothendieck construction, the unstraightening of $\mathrm{Y} \circ \Theta \circ u_a^*(\zeta)(\eta)$ corresponds to a C_p-functor of C_p-∞-categories which we denote by

$$- \otimes_{\mathbb{S}^0} A\colon \underline{\mathrm{Sp}}^{C_p} \to \underline{\mathrm{Mod}}_A.$$

Categories of modules behave in the expected way.

Proposition A.12. *Let A be a C_p-$\mathbb{E}_\infty$-algebra in C_p-spectra. Then the C_p-functor $- \otimes_{\mathbb{S}^0} A\colon \underline{\mathrm{Sp}}^{C_p} \to \underline{\mathrm{Mod}}_A$ participates in a C_p-adjunction which is fiberwise monadic.*

Proof. Notice that essentially by definition, the C_p-functor $- \otimes_{\mathbb{S}^0} A$ preserves coCartesian arrows. By (the dual to) [Lur17, Proposition 7.3.2.6], it suffices to check that $- \otimes_{\mathbb{S}^0} A$ admits a fiberwise right adjoint, which is classical. □

Remark A.13. The strategy outlined here generalizes straightforwardly to endow the G-∞-category of modules over a normed G-$\mathbb{E}_\infty$-ring spectrum with the structure of a G-symmetric monoidal structure for any finite group G.

Remark A.14. One expects a equivariant form of the Tannaka reconstruction theorem [Lur17, Propositions 7.1.2.6-7] by which a G-$\mathbb{E}_\infty$-ring A can be recovered from its category of modules endowed with its G-symmetric monoidal structure.

Normed equivariant ring spectra and higher Tambara functors

Bastiaan Cnossen, Rune Haugseng, Tobias Lenz, and Sil Linskens

July 11, 2024

Abstract

In this paper we extend equivariant infinite loop space theory to take into account multiplicative norms: For every finite group G, we construct a multiplicative refinement of the comparison between the ∞-categories of connective genuine G-spectra and space-valued Mackey functors, first proven by Guillou–May, and use this to give a description of connective normed equivariant ring spectra as space-valued Tambara functors.

In more detail, we first introduce and study a general notion of homotopy-coherent normed (semi)rings, and identify these with product-preserving functors out of a corresponding ∞-category of bispans. In the equivariant setting, this identifies space-valued Tambara functors with normed algebras with respect to a certain normed monoidal structure on grouplike G-commutative monoids in spaces. We then show that the latter is canonically equivalent to the normed monoidal structure on connective G-spectra given by the Hill–Hopkins–Ravenel norms. Combining our comparison with results of Elmanto–Haugseng and Barwick–Glasman–Mathew–Nikolaus, we produce normed ring structures on equivariant algebraic K-theory spectra.

Contents

1 Introduction

Infinite loop space theory has played an important role in algebraic topology since the 1970's, giving a way to construct interesting examples of spectra from space-level data. At its heart lies the *Recognition Theorem* [May72, BV73, Seg74], which in modern language describes connective spectra as commutative group objects in the ∞-category of spaces, i.e.

$$\mathsf{Sp}^{\geq 0} \simeq \mathsf{CGrp}(\mathsf{Spc}). \tag{1}$$

Such commutative groups arise in nature, for instance, by group-completing the classifying spaces of symmetric monoidal (∞-)categories. As an important example, applying this to the groupoid of finitely generated projective modules over a ring R with symmetric monoidal structure via direct sum yields the algebraic K-theory spectrum of the ring R [May74, Seg74].

In order to obtain spectra with algebraic structures, we need to upgrade (1) to take into account *multiplicative* structures. For 1-categorical inputs, such *multiplicative infinite loop spaces machines* have been considered for example by May [May77, May09] and Elmendorf–Mandell [EM06]. Working in the ∞-categorical framework, Gepner–Groth–Nikolaus [GGN15] both generalized and elucidated these constructions: they show that there is a canonical symmetric monoidal structure on the ∞-category $\mathsf{CMon}(\mathsf{Spc})$ of commutative monoids in spaces, which localizes to commutative groups, and that (1) uniquely upgrades to an equivalence of symmetric monoidal ∞-categories where we equip $\mathsf{Sp}^{\geq 0}$ with the smash product. The tensor product on $\mathsf{CGrp}(\mathsf{Spc})$ is an ∞-categorical analogue of the tensor product of abelian groups, so it is natural to think of a commutative algebra object of $\mathsf{CGrp}(\mathsf{Spc})$ as a commutative ring in Spc; as a direct consequence of the multiplicative comparison, we then have an equivalence

$$\mathsf{CAlg}(\mathsf{Sp}^{\geq 0}) \simeq \mathsf{CAlg}(\mathsf{CGrp}(\mathsf{Spc})) =: \mathsf{CRing}(\mathsf{Spc}) \tag{2}$$

between connective commutative ring spectra and commutative ring spaces.

A multiplicative equivariant recognition theorem

Our first goal is to extend the above story to equivariant spectra over a finite group G. While the study of such *equivariant infinite loop space machines* began in the late 70's (in unpublished work of Segal and Hauschild–May–Waner), the subject has experienced a renaissance in recent years. As part of this, its point-set level foundations have been rewritten and extended by May and his collaborators [GM11, GM17, MMO17], and new ∞-categorical approaches to the subject have been introduced by Barwick and collaborators [Bar17, BDG+16].

In the present paper, we will adopt the latter perspective. For this, recall from [CMNN20, A.1] that the ∞-category Sp_G of G-spectra, defined classically as the Dwyer–Kan localization of a suitable model category of orthogonal or symmetric spectra with G-action, admits a purely ∞-categorical description as

$$\mathsf{Sp}_G \simeq \mathsf{Fun}^{\times}(\mathsf{Span}(\mathbb{F}_G), \mathsf{Sp}),$$

that is, as product-preserving functors from a $(2,1)$-category of spans of finite G-sets to spectra; see also [GM11] for a model-categorical version.

From this equivalence and (1), one immediately obtains an *Equivariant Recognition Theorem*, in the form of a space-level description of connective G-spectra as

$$\mathsf{Sp}_G^{\geq 0} \simeq \mathsf{Fun}^{\times}_{\mathrm{grp}}(\mathsf{Span}(\mathbb{F}_G), \mathsf{Spc}); \tag{3}$$

here the right-hand side consists of functors $F\colon \mathsf{Span}(\mathbb{F}_G) \to \mathsf{Spc}$ that preserve products and that are *grouplike*, in the sense that for every G-set X the commutative multiplication given by

$$F(X) \times F(X) \simeq F(X \amalg X) \longrightarrow F(X)$$

makes $F(X)$ a commutative group. Analogously to the non-equivariant situation, such objects arise naturally from ∞-categorical data, and this provides one possible approach to equivariant algebraic K-theory [BGS20].

To shed some light on this equivalence, recall [Dre71] that a *Mackey functor* M for G consists of abelian groups $M(X)$ for every finite G-set X together with restriction and additive norm (or "transfer") maps

$$f^*\colon M(X) \longrightarrow M(Y), \quad f_{\oplus}\colon M(Y) \longrightarrow M(X)$$

for every morphism $f\colon Y \to X$ of G-sets, such that M takes disjoint unions to products, both restrictions and norms are functorial, and they compose according to a double coset formula. The zeroth homotopy groups of any G-spectrum form a Mackey functor, and Mackey functors are the most general coefficients for ordinary equivariant (co)homology [LMS86, §V.9]. The data of a Mackey functor can be neatly organized into a product-preserving functor

$$\mathsf{Span}(\mathbb{F}_G) \longrightarrow \mathsf{Ab},$$

or equivalently a functor $\mathsf{Span}(\mathbb{F}_G) \to \mathsf{Set}$ that preserves products and such that the induced (commutative) multiplication on the value at every G-set has inverses. Thus we may think of the equivalence (3) as saying that connective G-spectra are *space-valued Mackey functors*.

Just like a space-valued Mackey functor contains more information than a commutative group in the ∞-category of G-spaces (namely, in the form of additive norms), a multiplicative refinement of the equivalence (3) should not just take the ordinary symmetric monoidal structures on both sides into account (arising via the smash product and Day convolution, respectively), but additionally respect suitable *symmetric monoidal norms*. To make this precise, note that if $\mathscr{C}$ is any ∞-category with finite products, we can more generally define a *normed G-monoid* in $\mathscr{C}$ to be a functor

$$M\colon \mathsf{Span}(\mathbb{F}_G) \longrightarrow \mathscr{C}$$

that preserves finite products; this amounts to specifying a commutative monoid $M(G/H)$ with an action of the Weyl group $W_GH := N_GH/H$ for every subgroup H of G, together with restrictions $\mathrm{Res}^K_H\colon M(G/K) \to M(G/H)$ and norm maps $\mathrm{Nm}^K_H\colon M(G/H) \to M(G/K)$ for all subgroups $H \leqslant K \leqslant G$ as well as various coherences. The equivalence (2) can then be restated as saying that genuine G-spectra are normed G-monoids in spectra, while the equivalence (3) says that connective G-spectra are equivalently "grouplike" normed G-monoids in spaces, or *normed G-groups* for short.

On the other hand, taking $\mathscr{C}$ to be Cat_∞, we obtain the notion of a *normed G-∞-category* as the equivariant version of a symmetric monoidal ∞-category. Many important symmetric monoidal ∞-categories studied in equivariant homotopy theory turn out to admit natural refinements to normed G-∞-categories; in particular, there is a normed G-∞-category

$$\underline{\mathsf{Sp}}_G\colon G/H \mapsto \mathsf{Sp}_H$$

whose contravariant functoriality is given by the evident restrictions, and whose covariant functoriality encodes the smash product of equivariant spectra together with the *Hill–Hopkins–Ravenel norms* [HHR16]. We then prove:

Theorem A. (See Theorem 5.6.1) *The G-∞-category*

$$\underline{\mathsf{NMon}}_G(\mathsf{Spc})\colon G/H \mapsto \mathsf{Fun}^\times(\mathsf{Span}(\mathbb{F}_H), \mathsf{Spc})$$

of G-normed monoids in spaces has a canonical normed structure that localizes to $\underline{\mathsf{NGrp}}_G(\mathsf{Spc})$. Furthermore, the equivalence (3) upgrades to an equivalence

$$\underline{\mathsf{Sp}}_G^{\geq 0} \simeq \underline{\mathsf{NGrp}}_G(\mathsf{Spc})$$

of normed G-∞-categories, where the left-hand side carries the restriction of the normed structure described above.

Normed G-ring spectra

As a direct consequence of Theorem A, we obtain equivalences between connective G-spectra equipped with extra "parametrized algebraic structure" and G-commutative groups equipped with the same structure. To make this precise, note that by straightening–unstraightening we can equivalently regard a normed G-∞-category $\mathscr{C}$ as a cocartesian fibration

$$\mathscr{C}^{\otimes} \longrightarrow \mathsf{Span}(\mathbb{F}_G).$$

Following Bachmann–Hoyois [BH21] we define a *G-normed algebra* in $\mathscr{C}$ as a section $\mathsf{Span}(\mathbb{F}_G) \to \mathscr{C}^{\otimes}$ that takes the backward maps to cocartesian morphisms in $\mathscr{C}^{\otimes}$; this amounts to specifying a commutative algebra A in the underlying ∞-category $\mathscr{C}(G/G)$ together with suitably coherent *normed multiplications* $\mathrm{Nm}_H^G \mathrm{Res}_H^G A \to A$ for every $H \leqslant G$.

In particular, we get a notion of G-normed algebras in $\underline{\mathsf{Sp}}_G$, or *normed G-spectra* for short, which are generally expected to be equivalent to the objects obtained as strict commutative algebras in the 1-categories of symmetric or orthogonal G-spectra. Theorem A then shows that *connective* normed G-spectra can equivalently be described as normed algebras in $\underline{\mathsf{NGrp}}_G(\mathsf{Spc})$, i.e. as "normed G-rings." As our second main result, we then build on this comparison to give a space-level description of connective normed G-spectra, generalizing the result for $G = 1$ proven in [CHLL24]:

Theorem B. (See Theorem 5.6.3) *There is an equivalence of ∞-categories*

$$\mathsf{NAlg}_G(\mathsf{Sp}_G^{\geq 0}) \simeq \mathsf{Fun}^{\times}_{\mathrm{grp}}(\mathsf{Bispan}(\mathbb{F}_G), \mathsf{Spc}). \tag{4}$$

Here $\mathsf{Bispan}(\mathbb{F}_G)$ is the $(2,1)$-category of *bispans* of finite G-sets in the sense of [EH23]: its objects are finite G-sets, and morphisms are given by diagrams

$$A \xleftarrow{R} B \xrightarrow{N} C \xrightarrow{T} D; \tag{5}$$

the composition law in $\mathsf{Bispan}(\mathbb{F}_G)$ is somewhat involved and encodes both the Mackey double coset formulas for commuting restrictions past norms and transfers, as well as a distributivity relation between norms and transfers. Moreover, $\mathsf{Fun}^{\times}_{\mathrm{grp}}$ again denotes the full subcategory of those product-preserving functors that are *grouplike* in a suitable sense (see Definition 4.3.5 for details).

Recall [Tam93] that a *Tambara functor* X for a finite group G is an assignment of an abelian group $X(G/H)$ for every subgroup of G together with compatible restriction, transfer, and norm maps for every subgroup inclusion. A Tambara functor is thus a multiplicative enhancement of a Mackey functor, and this is precisely the structure existing on the zeroth equivariant homotopy groups of a strictly commutative G-ring spectrum, see [Bru07, §7.2] and [Ull13]. Tambara functors can equivalently be described [Str12] as grouplike product-preserving functors $\mathsf{Bispan}(\mathbb{F}_G) \to \mathsf{Set}$ (with restrictions, transfers, and norms corresponding to the functoriality in the components R, T, and N of the bispan (5), respectively), and we can therefore think of the equivalence (4) as identifying connective normed G-spectra with *space-valued Tambara functors*.

In fact, we deduce Theorem B from a much more general result: following Bachmann [Bac22], we consider *normed ∞-categories* as functors from suitable span ∞-categories into Cat_∞, and we give a general description of *normed (semi)rings* in this context in terms of product-preserving functors out of an ∞-category of bispans, see Theorems 4.2.4 and 4.3.6. This in particular allows us to deduce a version of Theorem B with fewer normed multiplications, in which case we can describe the corresponding connective normed algebras as a space-valued version of the *incomplete Tambara functors* considered by Blumberg–Hill [BH18].

Multiplicative equivariant K-theory

As a concrete application of Theorem B, we can construct normed multiplicative structures on equivariant algebraic K-theory spectra: Recall that Elmanto and Haugseng [EH23, §4.3] show that if E is a normed G-spectrum, then the assignment

$$H \mapsto \mathsf{Mod}_{E^H}(\mathsf{Sp}_H)$$

extends naturally to a functor

$$\mathsf{Bispan}(\mathbb{F}_G) \longrightarrow \mathsf{Cat}_\infty$$

that preserves products and takes values in the subcategory of stable ∞-categories and polynomial functors. Combining this with the polynomial functoriality of (connective) algebraic K-theory of Barwick, Glasman, Mathew, and Nikolaus [BGMN21], we obtain a space-valued Tambara functor given by

$$H \mapsto \Omega^\infty K(\mathsf{Mod}_{E^H}(\mathsf{Sp}_H)).$$

Now Theorem B identifies this with a normed G-spectrum; as the constructions involved are functorial, we obtain:

Corollary C. *Connective equivariant algebraic K-theory can be enhanced to a functor*

$$K\colon \mathsf{NAlg}_G(\mathsf{Sp}_G) \longrightarrow \mathsf{NAlg}_G(\mathsf{Sp}_G^{\geq 0}).$$

More generally, we obtain normed G-spectra from suitable normed stable ∞-categories [EH23, 4.3.2]. Specializing this as in [EH23, 4.3.9] we in particular obtain a refinement of connective equivariant algebraic K-theory of stable ∞-categories to a functor from symmetric monoidal stable ∞-categories to normed G-spectra. In the case where G is a finite 2-group, an entirely different approach to such a refinement has previously been worked out by Hilman [Hil22b]; to the best of our knowledge, ours is the first construction in this generality.

Related work

During the long history of equivariant infinite loop space theory, a wide range of notions of "G-commutative monoids" have been introduced and studied, for example Shimakawa's *special* Γ-*G-spaces* [Shi89], the operadic models of Guillou–May [GM17], various "ultra-commutative" models [Len20, LS23], and the ∞-categorical model [GM11, Bar17] used in this paper. All of these notions are known to be equivalent to each other [MMO17, Len23, Mar24], and in particular each of them comes with an equivariant recognition theorem relating the corresponding grouplike objects to connective G-spectra.

Since the early days of the subject, much effort went into the search for multiplicative refinements of these comparisons, with several breakthroughs in the last couple of years. In particular, Guillou–May–Merling–Osorno studied multiplicative properties of the operadic machine, culminating in the article [GMMO23] where they refine equivariant infinite loop space theory to an enriched multifunctor, allowing the construction of *non-commutative* G-ring spectra from space-level or categorical data. Yau [Yau24] recently improved this to a *symmetric* enriched multifunctor, which then in particular can also be used to produce *commutative* G-ring spectra.

In contrast to our approach, the aforementioned authors work with *strict* (non-parametrized) algebraic structures on the level of 1-categorical models. While commutative structures on symmetric/orthogonal G-spectra are expected to model ∞-categorical G-normed spectra, a symmetric monoidal or symmetric multifunctor structure on the functor from G-commutative monoids to connective G-spectra does *not* induce any such structure on the inverse functor, and accordingly there is no analogue of our Theorem B known in these settings. In fact, there are serious obstructions to achieving a complete space-level description of connective commutative G-ring spectra along these lines: for example, Lawson [Law09] proved that even for $G = 1$ not all connective commutative ring spectra arise from strictly commutative algebras in Γ-spaces.

Outline

In Section 2 we recall some necessary background about ∞-categories of spans and bispans. We then introduce the framework of *normed monoids*, *normed ∞-categories*, and *normed algebras* in Section 3 as a very mild generalization of work of Bachmann and Hoyois. As the main new result of that section, we construct a *Day convolution* normed structure on certain ∞-categories of product-preserving functors and give a description of normed algebras in it, see Proposition 3.3.1.

Specializing this, we then construct normed ∞-categories of normed monoids in Section 4, which in particular allows us to define *normed (semi)rings*. Combining the description of normed algebras with respect to the Day convolution structure with our results in [CHLL24], we then show that normed rings can be equivalently described as certain higher Tambara functors (Theorem 4.3.6).

In Section 5 we introduce and compare various normed ∞-categories related to equivariant homotopy theory, in particular proving Theorem A. Combining this with the results of the previous section, we then finally deduce Theorem B.

The paper ends with a short appendix on a *Borel construction* due to Hilman [Hil22a] that builds normed G-∞-categories from ordinary symmetric monoidal ∞-categories with G-action, which is used in various constructions in Section 5.

Notations and conventions

- We write $\mathbb{F}$ for the category of finite sets, and $\mathbf{n} := \{1, \ldots, n\}$ for the standard set with n elements. For an ∞-category $\mathscr{C}$, we write $\mathbb{F}[\mathscr{C}]$ for the finite coproduct completion of $\mathscr{C}$. When $\mathscr{C}$ is the orbit category $\mathbf{O}_G$ of a finite group G, we denote the category of finite G-sets by $\mathbb{F}_G = \mathbb{F}[\mathbf{O}_G]$.

- Functors that preserve *finite* products will be referred to as *product-preserving* for short, and similarly for coproducts. We will never speak about arbitrary products and coproducts.

- We write Cat_∞ for the ∞-category of ∞-categories and Spc for the ∞-category of spaces (a.k.a. ∞-groupoids).

- If $\mathscr{C}$ is an ∞-category, then we denote its underlying ∞-groupoid by $\mathscr{C}^{\simeq}$ or $\mathscr{C}_{\mathrm{eq}}$, depending on context.

- We write $\mathsf{Ar}(\mathscr{C}) := \mathsf{Fun}([1], \mathscr{C})$ for the *arrow ∞-category* of $\mathscr{C}$.

- Throughout, we use the word *subcategory* to refer to what is sometimes called a *replete subcategory*: that is, for us a subcategory $\mathscr{C}_0 \subseteq \mathscr{C}$ is always required to contain all equivalences between its objects. A subcategory is called *wide* if it in addition contains all objects.

2 Spans and bispans

The goal of this section is to recall some basic properties of ∞-categories of spans and bispans, and to formulate conditions guaranteeing that a (bi)span ∞-category admits (co)products.

2.1 Spans

Let us begin by recalling some basic definitions and results concerning ∞-categories of spans. Our main references for this are Barwick's original article [Bar17] and the more recent treatment in [HHLN23].

Definition 2.1.1. A *span pair* $(\mathscr{C}, \mathscr{C}_F)$ consists of an ∞-category $\mathscr{C}$ together with a wide subcategory $\mathscr{C}_F$ of "forward" maps, such that base changes of morphisms in $\mathscr{C}_F$ exist in $\mathscr{C}$ and are again contained in $\mathscr{C}_F$. We write $\mathsf{SpanPair}$ for the ∞-category of span pairs; a morphism $(\mathscr{C}, \mathscr{C}_F) \to (\mathscr{D}, \mathscr{D}_F)$ here is a functor $\mathscr{C} \to \mathscr{D}$ that preserves the forward maps as well as pullbacks along forward maps.

Remark 2.1.2. Both [Bar17] and [HHLN23] work more generally with so-called *adequate triples* $(\mathscr{C}, \mathscr{C}_F, \mathscr{C}_B)$. Span pairs correspond to the special case $\mathscr{C}_B = \mathscr{C}$.

Example 2.1.3. For any ∞-category $\mathscr{C}$, we always have the *minimal* span pair $(\mathscr{C}, \mathscr{C}^{\simeq})$. If $\mathscr{C}$ has all pullbacks, then we also have the *maximal* span pair $(\mathscr{C}, \mathscr{C})$.

[HHLN23, 2.12] constructs a functor

$$\mathsf{Span}\colon \mathsf{SpanPair} \longrightarrow \mathsf{Cat}_\infty,$$

sending a span pair $(\mathscr{C}, \mathscr{C}_F)$ to its *span ∞-category*

$$\mathsf{Span}_F(\mathscr{C}) := \mathsf{Span}(\mathscr{C}, \mathscr{C}_F).$$

This ∞-category has the same objects as $\mathscr{C}$, and a map in $\mathsf{Span}_F(\mathscr{C})$ from x to y is given by a *span*

$$x \xleftarrow{\;b\;} z \xrightarrow{\;f\;} y,$$

where f is in $\mathscr{C}_F$ and b is arbitrary; composition is given by taking pullbacks in $\mathscr{C}$. If $\mathscr{C}$ has all pullbacks, we abbreviate $\mathsf{Span}(\mathscr{C})$ for the span category associated to the span pair $(\mathscr{C}, \mathscr{C})$.

Example 2.1.4 ([HHLN23, 2.15])**.** We have $\mathsf{Span}_{\mathrm{eq}}(\mathscr{C}) = \mathsf{Span}(\mathscr{C}, \mathscr{C}^{\simeq}) \simeq \mathscr{C}^{\mathrm{op}}$.

Remark 2.1.5. The ∞-category $\mathsf{SpanPair}$ has limits, which are computed in Cat_∞ [HHLN23, 2.4], and the functor Span preserves these [HHLN23, 2.18].

We will need the following special case of Barwick's "unfurling" theorem:

Proposition 2.1.6. *Suppose $(\mathcal{B}, \mathcal{B}_F)$ is a span pair and $\Phi\colon \mathcal{B} \to \mathsf{Cat}_\infty$ is a functor such that*

- *for every morphism $f\colon b \to b'$ in $\mathcal{B}_F$, the functor $f_! = \Phi(f)$ has a right adjoint f^*,*
- *and for every pullback square*

$$\begin{array}{ccc} a' & \xrightarrow{f'} & b' \\ {\scriptstyle\alpha}\big\downarrow & \lrcorner & \big\downarrow{\scriptstyle\beta} \\ a & \xrightarrow[f]{} & b \end{array}$$

in $\mathcal{B}$ with f in $\mathcal{B}_F$, the induced Beck–Chevalley transformation

$$\alpha_! f'^* \longrightarrow f^* \beta_!$$

is an equivalence.

Let $p\colon \mathcal{E} \to \mathcal{B}$ be the cocartesian fibration for Φ, and write $\mathcal{E}_{F\text{-cart}}$ for the subcategory containing the morphisms that are p-cartesian over morphisms in $\mathcal{B}_F$. Then $(\mathcal{E}, \mathcal{E}_{F\text{-cart}})$ is a span pair, p is a morphism of span pairs, and

$$\mathsf{Span}(p)^{\mathrm{op}}\colon \mathsf{Span}_{F\text{-cart}}(\mathcal{E})^{\mathrm{op}} \longrightarrow \mathsf{Span}_F(\mathcal{B})^{\mathrm{op}}$$

is the cocartesian fibration for a functor $\mathsf{Span}_F(\mathcal{B})^{\mathrm{op}} \to \mathsf{Cat}_\infty$ that restricts to Φ on $\mathcal{B}$ and to the functor obtained by passing to right adjoints from Φ on $\mathcal{B}_F^{\mathrm{op}}$.

Proof. It follows from [Bar17, 11.6] that $(\mathcal{E}, \mathcal{E}_{F\text{-cart}})$ is a span pair, that p is a morphism of span pairs, and that $\mathsf{Span}(p)^{\mathrm{op}}$ is a cocartesian fibration. For the convenience of the reader we recall the proof, giving some additional details. It follows from [Bar17, 11.2] that $(\mathcal{E}, \mathcal{E}_{F\text{-cart}})$ is a span pair, and the pullback

$$\begin{array}{ccc} w & \xrightarrow{\bar{f}'} & z \\ {\scriptstyle\bar{g}'}\big\downarrow & \lrcorner & \big\downarrow{\scriptstyle\bar{g}} \\ x & \xrightarrow[\bar{f}]{} & y \end{array}$$

of $\bar{f}\colon x \to y$ in $\mathcal{E}_{F\text{-cart}}$ over $f\colon a \to b$ along a morphism $\bar{g}\colon z \to y$ over $g\colon c \to b$ is obtained by taking the pullback

$$\begin{array}{ccc} d & \xrightarrow{f'} & c \\ {\scriptstyle g'}\big\downarrow & \lrcorner & \big\downarrow{\scriptstyle g} \\ a & \xrightarrow[f]{} & b \end{array}$$

in $\mathcal{B}$, picking a p-cartesian morphism $\bar{f}'\colon w \to z$ over f', and letting $\bar{g}'$ be the unique factorization of $\bar{g}\bar{f}'$ through the p-cartesian morphism $\bar{f}$.

To show that $\mathsf{Span}(p)^{\mathrm{op}}$ is a cocartesian fibration, it suffices to show that any span

$$x \xleftarrow{f} y \xrightarrow{g} z$$

in $\mathsf{Span}_{F\text{-cart}}(\mathcal{E})^{\mathrm{op}}$, where f is p-cartesian over $\mathcal{B}_F$ and g is p-cocartesian, is a cocartesian morphism, since then $\mathsf{Span}_{F\text{-cart}}(\mathcal{E})^{\mathrm{op}}$ has all cocartesian lifts of morphisms in $\mathsf{Span}_F(\mathcal{B})^{\mathrm{op}}$. To see this we apply [Bar17, 12.2], in the guise of [HHLN23, 3.1]:

- Condition (1) is immediate since p is a cocartesian fibration.
- Unwinding the definitions, condition (2) says that given a pullback square

$$\begin{array}{ccc} a & \xrightarrow{g'} & b' \\ {\scriptstyle f'}\downarrow & \lrcorner & \downarrow{\scriptstyle f} \\ b & \xrightarrow[g]{} & c \end{array}$$

  in $\mathcal{B}$ with f in $\mathcal{B}_F$ and a commutative square

$$\begin{array}{ccc} f'^{*}x & \xrightarrow{\gamma} & y \\ {\scriptstyle \bar{f}'}\downarrow & & \downarrow{\scriptstyle \phi} \\ x & \xrightarrow[\bar{g}]{} & g_! x \end{array}$$

  where $\bar{g}$ is p-cocartesian over g and $\bar{f}'$ is p-cartesian over f', then γ is p-cocartesian if and only if ϕ lies in $\mathcal{E}_{F\text{-cart}}$ and the square is a pullback. Indeed, in the former case ϕ factors as the canonical map $g'_! f'^{*}x \to f^{*}g_! x$ followed by a cartesian morphism over f, while in the latter case γ factors as a cocartesian morphism over g' followed by the same map. Since this Beck–Chevalley map is by assumption invertible, the two conditions are equivalent.

It remains to identify the fibrations we get over $\mathcal{B}$ and $\mathcal{B}_F^{\mathrm{op}}$. Since the functor $\mathsf{Span}(-)$ is compatible with pullbacks, we see that over $\mathcal{B}$ we recover $p\colon \mathcal{E} \to \mathcal{B}$, while over $\mathcal{B}_F$ we get $\mathsf{Span}(\mathcal{E}_F, \mathcal{E}_{F,\mathrm{fw}}, \mathcal{E}_{F\text{-cart}}) \to \mathcal{B}_F^{\mathrm{op}}$, where $\mathcal{E}_F := \mathcal{E} \times_{\mathcal{B}} \mathcal{B}_F$ and $\mathcal{E}_{F,\mathrm{fw}}$ denotes the subcategory of morphisms that map to equivalences in $\mathcal{B}_F^{\mathrm{op}}$. This is the cocartesian fibration that describes the same functor as the cartesian fibration $\mathcal{E}_F \to \mathcal{B}_F$, by [BGN18, 1.4] or [HHLN23, 3.18]. □

2.2 Products in span ∞-categories

In this subsection we provide criteria for ∞-categories of spans to have products and coproducts.

Definition 2.2.1. Recall that an ∞-category $\mathscr{C}$ is called *extensive* if $\mathscr{C}$ has finite coproducts and the coproduct functor

$$\amalg\colon \prod_{i=1}^{n} \mathscr{C}_{/x_i} \longrightarrow \mathscr{C}_{/\coprod_i x_i}$$

is an equivalence for all objects $x_1, \ldots, x_n \in \mathscr{C}$. A span pair $(\mathscr{C}, \mathscr{C}_F)$ is called *extensive* if the following conditions are satisfied:

- $\mathscr{C}$ is extensive,
- the morphisms in $\mathscr{C}_F$ are closed under finite coproducts,
- and for every $x \in \mathscr{C}$, the maps $\emptyset \to x$ and $x \amalg x \to x$ are in $\mathscr{C}_F$.

More generally, we say that $(\mathscr{C}, \mathscr{C}_F)$ is *weakly extensive* if

- $\mathscr{C}$ has finite coproducts,
- the morphisms in $\mathscr{C}_F$ are closed under finite coproducts,
- and the coproduct functor

  $$\amalg\colon \prod_{i=1}^{n} \mathscr{C}^F_{/x_i} \longrightarrow \mathscr{C}^F_{/\amalg_i x_i}$$

  is an equivalence for all $n \geq 0$ and $x_1, \ldots, x_n \in \mathscr{C}$. Here $\mathscr{C}^F_{/y}$ denotes the full subcategory of $\mathscr{C}_{/y}$ spanned by those maps $z \to y$ that belong to F.

If $\mathscr{C}$ is an extensive ∞-category, then a wide subcategory $\mathscr{C}_F \subseteq \mathscr{C}$ is called a *(weakly) extensive subcategory* if the pair $(\mathscr{C}, \mathscr{C}_F)$ is (weakly) extensive span pair.

Remark 2.2.2. Note that a span pair $(\mathscr{C}, \mathscr{C}_F)$ is extensive if and only if $\mathscr{C}$ and $\mathscr{C}_F$ are both extensive ∞-categories and the inclusion $\mathscr{C}_F \hookrightarrow \mathscr{C}$ preserves finite coproducts. Also note that every extensive span pair is weakly extensive.

Remark 2.2.3. Let $(\mathscr{C}, \mathscr{C}_F)$ be a span pair such that the morphisms in $\mathscr{C}_F$ are closed under finite coproducts. Then the coproduct functor $\prod_{i=1}^{n} \mathscr{C}^F_{/x_i} \to \mathscr{C}^F_{/\amalg_i x_i}$ admits a right adjoint $\mathscr{C}^F_{/\amalg_i x_i} \to \prod_{i=1}^{n} \mathscr{C}^F_{/x_i}$ given by pullback along the maps $x_i \to \amalg_i x_i$, see [Lur09, 5.2.5.1], and it follows that $(\mathscr{C}, \mathscr{C}_F)$ is weakly extensive if and only if this functor is an equivalence. In this case, the canonical squares

$$\begin{array}{ccc} y_i & \longrightarrow & \amalg_i y_i \\ {\scriptstyle f_i}\downarrow & & \downarrow{\scriptstyle \amalg_i f_i} \\ x_i & \longrightarrow & \amalg_i x_i \end{array}$$

are pullback squares for all morphisms $f_i\colon y_i \to x_i$ in $\mathscr{C}_F$.

One may similarly characterize extensiveness of $\mathscr{C}$ by means of the right adjoint $\mathscr{C}_{/\amalg_i x_i} \to \prod_{i=1}^n \mathscr{C}_{/x_i}$ to the coproduct functor; in this case we need to assume that the morphism $\emptyset \to x$ is in $\mathscr{C}_F$ for each object x to guarantee that the relevant pullbacks exist.

Proposition 2.2.4. *A span pair $(\mathscr{C}, \mathscr{C}_F)$ is weakly extensive if and only if the following conditions hold:*

- *the ∞-category $\mathscr{C}$ has finite coproducts,*
- *the coproduct functor $\mathscr{C} \times \mathscr{C} \to \mathscr{C}$ is a morphism of span pairs (i.e. morphisms in $\mathscr{C}_F$ are closed under coproducts and coproducts of pullbacks of morphisms in $\mathscr{C}_F$ are again pullbacks),*
- *and the commutative squares*

$$\begin{array}{ccc} x \amalg x & \longrightarrow & y \amalg y \\ \downarrow & & \downarrow \\ x & \longrightarrow & y \end{array} \qquad \begin{array}{ccc} \emptyset & \longrightarrow & \emptyset \\ \downarrow & & \downarrow \\ x & \longrightarrow & y \end{array}$$

are pullbacks for all morphisms $x \to y$ in $\mathscr{C}_F$.

The pair $(\mathscr{C}, \mathscr{C}_F)$ is extensive if and only if in addition we have:

- *the above two squares are pullbacks for* ***any*** *morphism $x \to y$ in $\mathscr{C}$,*
- *the maps $\emptyset \to x$ and $x \amalg x \to x$ are in $\mathscr{C}_F$ for all $x \in \mathscr{C}$.*

Proof. First assume that $(\mathscr{C}, \mathscr{C}_F)$ is weakly extensive. By assumption, $\mathscr{C}$ has finite coproducts and morphisms in $\mathscr{C}_F$ are closed under finite coproducts. For the second condition, consider pullback squares

$$\begin{array}{ccc} x'_i & \xrightarrow{h_i} & x_i \\ {\scriptstyle f'_i}\downarrow & \lrcorner & \downarrow{\scriptstyle f_i} \\ y'_i & \xrightarrow{g_i} & y_i \end{array}$$

for $i = 1, \ldots, n$, with $f_i \in \mathscr{C}_F$. We need to show that their coproduct is again a pullback square, or, equivalently, that the map

$$\amalg_i x'_i \longrightarrow (\amalg_i x_i) \times_{\amalg_i y_i} (\amalg_i y'_i)$$

is an equivalence in $\mathscr{C}^F_{/\amalg_i y'_i}$. But since $(\mathscr{C}, \mathscr{C}_F)$ is weakly extensive, this may be checked after pulling back along each of the maps $y'_i \to \amalg_i y'_i$, where it becomes clear. For the third condition, we must show that the maps $x \amalg x \to (y \amalg y) \times_y x$ in $\mathscr{C}^F_{/y \amalg y}$ and $\emptyset \to \emptyset \times_y x$ in $\mathscr{C}^F_{/\emptyset}$ are equivalences. The latter is clear since

$\mathscr{C}^F_{/\emptyset} \xrightarrow{\sim} *$. For the former, it again suffices to check this after pulling back along the two inclusions $y \to y \amalg y$, where it is also clear.

For the converse, assume that the first three conditions in the proposition are satisfied. We show that $(\mathscr{C}, \mathscr{C}_F)$ is a weakly extensive span pair. It suffices to prove that the pullback functor

$$\mathscr{C}^F_{/\coprod_{i=1}^n x_i} \longrightarrow \prod_{i=1}^n \mathscr{C}^F_{/x_i}$$

is an equivalence when $n = 0$ and $n = 2$. For $n = 0$ we want to show that $\mathscr{C}^F_{/\emptyset} \simeq *$, which follows because for $x \to \emptyset$ in $\mathscr{C}_F$ we have a pullback square

$$\begin{array}{ccc} \emptyset & \longrightarrow & \emptyset \\ \downarrow & \lrcorner & \downarrow \\ x & \longrightarrow & \emptyset, \end{array}$$

so that $\emptyset \to x$ is an equivalence. For $n = 2$, the coproduct functor determines a left adjoint $\amalg \colon \mathscr{C}^F_{/x_1} \times \mathscr{C}^F_{/x_2} \to \mathscr{C}^F_{/x_1 \amalg x_2}$ of the pullback functor by [Lur09, 5.2.5.1], and it will suffice that both the unit and the counit are equivalences. For the counit, consider a map $y \to x_1 \amalg x_2$ in $\mathscr{C}_F$, and let $y_i \to x_i$ be the pullback of y along the inclusion of x_i in the coproduct, which is again in $\mathscr{C}_F$; we must show that the canonical map $y_1 \amalg y_2 \to y$ is an equivalence. To see this, consider the commutative diagram

$$\begin{array}{ccccc} y_1 \amalg y_2 & \longrightarrow & y \amalg y & \longrightarrow & y \\ \downarrow & & \downarrow & & \downarrow \\ x_1 \amalg x_2 & \longrightarrow & (x_1 \amalg x_2) \amalg (x_1 \amalg x_2) & \longrightarrow & x_1 \amalg x_2. \end{array}$$

Here the left square is cartesian since it's a coproduct of two pullback squares along morphisms in $\mathscr{C}_F$, and the right square is cartesian since it's a square of fold maps for a morphism in $\mathscr{C}_F$. The composite square is then cartesian, and the bottom horizontal composite is the identity, which implies that the top horizontal composite is indeed an equivalence.

We now show that the unit of the adjunction is an equivalence. Given morphisms $y_1 \to x_1$ and $y_2 \to x_2$ in $\mathscr{C}_F$, this amounts to showing that the canonical squares

$$\begin{array}{ccc} y_i & \longrightarrow & y_1 \amalg y_2 \\ \downarrow & & \downarrow \\ x_i & \longrightarrow & x_1 \amalg x_2 \end{array}$$

are pullback squares. Writing $x_1 = x_1 \amalg \emptyset$ and similarly for x_2, y_1 and y_2, these squares can be expressed as a coproduct of squares we know are pullbacks along morphisms in $\mathscr{C}_F$, hence are pullback squares by assumption. This finishes the proof of the characterization of being weakly extensive.

The proof for extensive span pairs is identical; the additional assumption that $\mathscr{C}_F$ contains the maps $\emptyset \to x$ and $x \amalg x \to x$ is to ensure that all the relevant pullbacks that appear in the proof exist in $\mathscr{C}$. □

We will now show that the extensiveness properties on a span pair imply good behavior of products and coproducts in the associated span ∞-category.

Proposition 2.2.5 (cf. [BH21, C.3])**.** *Suppose $(\mathscr{C}, \mathscr{C}_F)$ is a span pair.*

(1) If $(\mathscr{C}, \mathscr{C}_F)$ is weakly extensive, then the coproduct in $\mathscr{C}$ gives a product in $\mathsf{Span}_F(\mathscr{C})$.

(2) If $(\mathscr{C}, \mathscr{C}_F)$ is extensive, then the coproduct in $\mathscr{C}$ is also a coproduct in $\mathsf{Span}_F(\mathscr{C})$. Moreover, the ∞-category $\mathsf{Span}_F(\mathscr{C})$ is semiadditive.

For the last statement, recall that an ∞-category $\mathscr{D}$ is called *semiadditive* if it admits finite products and coproducts, the unique morphism $\emptyset \to *$ is an equivalence, and for all $x_1, x_2 \in \mathscr{D}$, the morphism

$$\begin{pmatrix} \mathrm{id}_{x_1} & 0 \\ 0 & \mathrm{id}_{x_2} \end{pmatrix} : x_1 \amalg x_2 \longrightarrow x_1 \times x_2$$

is an equivalence, where 0 denotes the unique map that factors through $*$.

Proof. For the first part apply [BH21, C.21(2)] together with the characterization from Proposition 2.2.4 to the adjunctions

$$\amalg : \mathscr{C} \times \mathscr{C} \rightleftarrows \mathscr{C} : \Delta \qquad \text{and} \qquad \{\emptyset\} : * \rightleftarrows \mathscr{C} : p.$$

For the second part apply part (1) of the same corollary, to see that $\emptyset$ is also initial and $\mathsf{Span}(\amalg)$ is also *left* adjoint to the restriction, so that $\mathsf{Span}_F(\mathscr{C})$ has finite coproducts. It is then clear that $\mathsf{Span}_F(\mathscr{C})$ is pointed. To see that it is semiadditive, we now observe that in any pointed ∞-category with finite (co)products the canonical comparison map $x \amalg y \to x \times y$ factors as

$$x \amalg y \simeq (x \times 0) \amalg (0 \times y) \longrightarrow (x \amalg 0) \times (0 \amalg y) \simeq x \times y,$$

so it is an equivalence in the case of $\mathsf{Span}_F(\mathscr{C})$ as the coproduct functor is a right adjoint by the above, and hence preserves products. □

Remark 2.2.6. Our definition of "extensive span pairs" is closely related to Barwick's *disjunctive triples* [Bar17, 5.2]. Thus, Proposition 2.2.5 is essentially a variant of the proof of semiadditivity in [Bar17, 4.3 and 5.8].

2.3 Bispans

Finally, let us recall ∞-categories of *bispans* from [EH23].

Definition 2.3.1. A *bispan triple* $(\mathscr{C}, \mathscr{C}_F, \mathscr{C}_L)$ consists of an ∞-category $\mathscr{C}$ together with two wide subcategories $\mathscr{C}_F, \mathscr{C}_L \subseteq \mathscr{C}$ such that both $(\mathscr{C}, \mathscr{C}_F)$ and $(\mathsf{Span}_F(\mathscr{C})^{\mathrm{op}}, \mathscr{C}_L)$ are span pairs. In this case, we define

$$\mathsf{Bispan}_{F,L}(\mathscr{C}) := \mathsf{Span}_L(\mathsf{Span}_F(\mathscr{C})^{\mathrm{op}}).$$

For $\mathscr{C}_L = \mathscr{C}$ we abbreviate this to $\mathsf{Bispan}_F(\mathscr{C})$, and if moreover also $\mathscr{C}_F = \mathscr{C}$, we will simply write $\mathsf{Bispan}(\mathscr{C})$.

Remark 2.3.2. By [EH23, 2.5.2(1)], a triple $(\mathscr{C}, \mathscr{C}_F, \mathscr{C}_L)$ is a bispan triple if and only if it satisfies the following more explicit conditions:

(1) Both $(\mathscr{C}, \mathscr{C}_F)$ and $(\mathscr{C}, \mathscr{C}_L)$ are span pairs.

(2) Let $\mathscr{C}^L_{/x} \subseteq \mathscr{C}_{/x}$ again denote the full subcategory spanned by the maps to x that lie in $\mathscr{C}_L$. Then the functor $f^*\colon \mathscr{C}^L_{/y} \to \mathscr{C}^L_{/x}$ given by pullback along f has a right adjoint f_* for every map f in $\mathscr{C}_F$.

(3) For any pullback square

$$\begin{array}{ccc} x' & \xrightarrow{f'} & y' \\ {\scriptstyle\xi}\downarrow & \lrcorner & \downarrow{\scriptstyle\eta} \\ x & \xrightarrow[f]{} & y \end{array}$$

with f a map in $\mathscr{C}_F$, the commutative square

$$\begin{array}{ccc} \mathscr{C}^L_{/y} & \xrightarrow{f^*} & \mathscr{C}^L_{/x} \\ {\scriptstyle\eta^*}\downarrow & & \downarrow{\scriptstyle\xi^*} \\ \mathscr{C}^L_{/y'} & \xrightarrow[f'^*]{} & \mathscr{C}^L_{/x'} \end{array}$$

is *right adjointable*, i.e. the Beck–Chevalley transformation $\eta^* f_* \to f'_* \xi^*$ is invertible.

Note that if $\mathscr{C}_L = \mathscr{C}$, then condition (2) precisely says that $\mathscr{C}$ is locally cartesian closed. In this case, condition (3) is actually automatic as it can be checked after passing to left adjoints.

Definition 2.3.3. Let $(\mathscr{C}, \mathscr{C}_F, \mathscr{C}_L)$ and $(\mathscr{D}, \mathscr{D}_F, \mathscr{D}_L)$ be bispan triples. A *morphism of bispan triples* is a functor $\Phi\colon \mathscr{C} \to \mathscr{D}$ that induces morphisms of span pairs $(\mathscr{C}, \mathscr{C}_F) \to (\mathscr{D}, \mathscr{D}_F)$, $(\mathscr{C}, \mathscr{C}_L) \to (\mathscr{D}, \mathscr{D}_L)$, and

$$(\mathsf{Span}_F(\mathscr{C})^{\mathrm{op}}, \mathscr{C}_L) \longrightarrow (\mathsf{Span}_F(\mathscr{D})^{\mathrm{op}}, \mathscr{D}_L).$$

Remark 2.3.4. In order to unpack the final condition, let us describe pullbacks in $\mathsf{Span}_F(\mathscr{C})^{\mathrm{op}}$ along morphisms in $\mathscr{C}_L$ more concretely, for which it will be enough to describe pullbacks of backwards and forwards maps individually:

- Given a forward map $x \xleftarrow{=} x \xrightarrow{g} y$, its pullback along a map $l\colon z \to y$ in $\mathscr{C}_L$ is given by

  $$\begin{array}{ccccc} d & = & d & \longrightarrow & z \\ \| & & \| & \lrcorner & \| \\ d & = & d & \longrightarrow & z \\ \downarrow & \llcorner & \downarrow & \lrcorner & \downarrow{\scriptstyle l} \\ x & = & x & \xrightarrow{g} & y, \end{array}$$

  see [EH23, 2.5.10].

- Given a backwards map $x \xleftarrow{f} y \xrightarrow{=} y$ with f in $\mathscr{C}_F$, [EH23, 2.5.12] shows that its pullback along $l\colon z \to y$ is of the form

  $$\begin{array}{ccccc} e & \longleftarrow & d & \xrightarrow{\epsilon} & z \\ \| & & \| & \lrcorner & \| \\ e & \longleftarrow & d & \xrightarrow{\epsilon} & z \\ {\scriptstyle f_*l}\downarrow & \llcorner & \downarrow{\scriptstyle f^*f_*l} & & \downarrow{\scriptstyle l} \\ x & \xleftarrow[f]{} & y & = & y, \end{array}$$

  where ϵ is the counit map $f^*f_*l \to l$.

In particular, we see that if $\Phi\colon \mathscr{C} \to \mathscr{D}$ is such that $(\mathscr{C}, \mathscr{C}_L) \to (\mathscr{D}, \mathscr{D}_L)$ and $(\mathscr{C}, \mathscr{C}_F) \to (\mathscr{D}, \mathscr{D}_F)$ are maps of span pairs, then Φ is a a map of bispan triples if and only if the Beck–Chevalley map

$$\Phi \circ f_* \longrightarrow \Phi(f)_* \circ \Phi$$

induced by the commutative square

$$\begin{array}{ccc} \mathscr{C}^L_{/y} & \xrightarrow{f^*} & \mathscr{C}^L_{/x} \\ {\scriptstyle \Phi}\downarrow & & \downarrow{\scriptstyle \Phi} \\ \mathscr{D}^L_{/\Phi(y)} & \xrightarrow[\Phi(f)^*]{} & \mathscr{D}^L_{/\Phi(x)} \end{array}$$

is an equivalence.

Proposition 2.3.5. *Suppose $(\mathscr{C}, \mathscr{C}_F, \mathscr{C}_L)$ is a bispan triple such that both of the span pairs $(\mathscr{C}, \mathscr{C}_F)$ and $(\mathscr{C}, \mathscr{C}_L)$ are weakly extensive. Then the span pair $(\mathsf{Span}_F(\mathscr{C})^{\mathrm{op}}, \mathscr{C}_L)$ is also weakly extensive. In particular, $\mathsf{Bispan}_{F,L}(\mathscr{C})$ has finite products, and these are given by coproducts in $\mathscr{C}$.*

Proof. By Proposition 2.2.5(1), the coproduct in $\mathscr{C}$ gives a product in $\mathsf{Span}_F(\mathscr{C})$ and hence a coproduct in $\mathsf{Span}_F(\mathscr{C})^{\mathrm{op}}$.

We now claim that pullback squares along $\mathscr{C}_L$ are closed under finite coproducts. Using the explicit description of pullbacks from the previous remark, the only non-obvious part of this is that, given $f_i \colon y_i \to x_i$ in $\mathscr{C}_F$ and $l_i \colon z_i \to y_i$ in $\mathscr{C}_L$ for $i = 1, 2$, we have

$$(f_1 \amalg f_2)_*(l_1 \amalg l_2) \simeq f_{1,*}(l_1) \amalg f_{2,*}(l_2).$$

To see this we use Proposition 2.2.4 with the argument from [EH23, 2.6.12]: Given $g \colon a \to x_1 \amalg x_2$ in $\mathscr{C}_L$, if $g_i \colon a_i \to x_i$ for $i = 1, 2$ are the pullbacks along the summand inclusions, we get

$$\begin{aligned}
\mathsf{Map}_{\mathscr{C}^L_{/x_1 \amalg x_2}}(g, f_{1,*}(l_1) \amalg f_{2,*}(l_2)) &\simeq \mathsf{Map}_{\mathscr{C}^L_{/x_1}}(g_1, f_{1,*}(l_1)) \times \mathsf{Map}_{\mathscr{C}^L_{/x_2}}(g_2, f_{2,*}(l_2)) \\
&\simeq \mathsf{Map}_{\mathscr{C}^L_{/y_1}}(f_1^* g_1, l_1) \times \mathsf{Map}_{\mathscr{C}^L_{/y_2}}(f_2^* g_2, l_2) \\
&\simeq \mathsf{Map}_{\mathscr{C}^L_{/y_1 \amalg y_2}}(f_1^* g_1 \amalg f_2^* g_2, l_1 \amalg l_2) \\
&\simeq \mathsf{Map}_{\mathscr{C}^L_{/y_1 \amalg y_2}}((f_1 \amalg f_2)^*(g_1 \amalg g_2), l_1 \amalg l_2) \\
&\simeq \mathsf{Map}_{\mathscr{C}^L_{/x_1 \amalg x_2}}(g, (f_1 \amalg f_2)_*(l_1 \amalg l_2)).
\end{aligned}$$

The remaining part of the conditions for a weakly extensive span pair hold because they by assumption hold for $(\mathscr{C}, \mathscr{C}_L)$. With this established, the final statement is another instance of Proposition 2.2.5(1). □

3 Normed ∞-categories

We recall the definition of normed ∞-categories and normed algebras from [BH21, Bac22] and give various examples of normed ∞-categories.

3.1 Normed monoids

Our starting point is the following generalization of the notion of a commutative monoid:

Definition 3.1.1. Let $F = (\mathscr{F}, \mathscr{F}_N)$ be a weakly extensive span pair and let $\mathscr{C}$ be an ∞-category with finite products. An *F-normed monoid in $\mathscr{C}$* is a product-preserving functor

$$M \colon \mathsf{Span}_N(\mathscr{F}) \longrightarrow \mathscr{C}.$$

We denote its contravariant functoriality by $f^* \colon M(Y) \to M(X)$ for morphisms $f \colon X \to Y$ in $\mathscr{F}$, and refer to these maps as *restriction maps*. We denote its covariant functoriality by either $n_\oplus \colon M(X) \to M(Y)$ or $n_\otimes \colon M(X) \to M(Y)$ for morphisms $n\colon X \to Y$ in $\mathscr{F}_N$, and refer to these maps as *(additive/multiplicative) norm maps*. We write

$$\mathsf{NMon}_F(\mathscr{C}) := \mathsf{Fun}^{\times}(\mathsf{Span}_N(\mathscr{F}), \mathscr{C})$$

for the full subcategory of $\mathsf{Fun}(\mathsf{Span}_N(\mathscr{F}), \mathscr{C})$ spanned by the F-normed monoids.

Observation 3.1.2. If F is actually extensive (and not only weakly so), then semiadditivity of $\mathsf{Span}_N(\mathscr{F})$ implies that all its objects carry unique commutative monoid structures, and so the values $M(X)$ of an F-normed monoid at $X \in \mathscr{F}$ inherit commutative monoid structures in $\mathscr{C}$. In fact, by [GGN15, 2.5] we get an equivalence

$$\mathsf{NMon}_F(\mathscr{C}) \simeq \mathsf{NMon}_F(\mathsf{CMon}(\mathscr{C})) \tag{6}$$

inverse to the forgetful functor.

Observation 3.1.3. If $\mathscr{C}$ is presentable and $\mathscr{F}$ is small, then $\mathsf{NMon}_F(\mathscr{C})$ is an accessible localization of $\mathsf{Fun}(\mathsf{Span}_N(\mathscr{F}), \mathscr{C})$, and so is a presentable ∞-category.

Let us discuss various examples of normed monoids:

Example 3.1.4. Our main example of an extensive span pair is the pair $F = (\mathbb{F}_G, \mathbb{F}_G)$ where $\mathbb{F}_G$ is the category of finite G-sets for a finite group G. In this case, F-normed monoids in $\mathscr{C}$ are also known as $\mathscr{C}$-valued *G-Mackey functors*:

$$\mathsf{Mack}_G(\mathscr{C}) := \mathsf{Fun}^{\times}(\mathsf{Span}(\mathbb{F}_G), \mathscr{C}).$$

More generally, we obtain a notion of *incomplete G-Mackey functors* by taking $F = (\mathbb{F}_G, I)$ for some weakly extensive subcategory $I \subseteq \mathbb{F}_G$:

$$\mathsf{Mack}^I_G(\mathscr{C}) := \mathsf{NMon}_{(\mathbb{F}_G, I)}(\mathscr{C}) = \mathsf{Fun}^{\times}(\mathsf{Span}_I(\mathbb{F}_G), \mathscr{C}).$$

These are most typically considered when $I \subseteq \mathbb{F}_G$ is in fact an extensive subcategory of $\mathbb{F}_G$ (and not only weakly extensive), in which case I is usually called an *indexing system for G* [BH18, 1.2 and 1.4].

Remark 3.1.5. To see how our approach relates to classical equivariant infinite loop space theory, consider an indexing system $I \subseteq \mathbb{F}_G$. By the discussion after [Rub21, 3.9], we can associate to I a so-called *N_∞-operad* $\mathscr{O}$ in G-spaces, and all N_∞-operads arise this way; see also [GW18, BP21]. The main result of [Mar24] connects space-valued Mackey-functors to N_∞-algebras by showing that $\mathsf{Mack}^I_G(\mathsf{Spc})$ is equivalent to the Dwyer–Kan localization of the 1-category of $\mathscr{O}$-algebras in G-spaces at a certain class of equivariant weak equivalences.

Example 3.1.6. Specializing example Example 3.1.4 to the trivial group, we obtain the extensive span pair $(\mathbb{F}, \mathbb{F})$, where $\mathbb{F}$ is the category of finite sets. By [BH21, C.1] there is an equivalence

$$\mathsf{NMon}_{\mathbb{F}}(\mathscr{C}) \simeq \mathsf{CMon}(\mathscr{C})$$

between $\mathbb{F}$-normed monoids in $\mathscr{C}$ and commutative monoids in $\mathscr{C}$, defined as functors $\mathbb{F}_* \to \mathscr{C}$ satisfying the Segal condition.

Example 3.1.7. Let $\mathscr{F}$ be an extensive ∞-category and let $\mathscr{F}_{\text{fold}}$ be the wide subcategory whose morphisms are finite coproducts of fold maps $\coprod_n x \to x$ for $x \in \mathscr{F}$ and $n \geq 0$. Then the pair $(\mathscr{F}, \mathscr{F}_{\text{fold}})$ is an extensive span pair, and [BH21, C.5] provides an equivalence

$$\mathsf{NMon}_{(\mathscr{F},\mathscr{F}_{\text{fold}})}(\mathscr{C}) \simeq \mathsf{Fun}^{\times}(\mathscr{F}^{\text{op}}, \mathsf{CMon}(\mathscr{C})).$$

Example 3.1.8. Given a span pair $F = (\mathscr{F}, \mathscr{F}_N)$ and an object $x \in \mathscr{C}$, we may consider the wide subcategory $\mathscr{F}_{/x,N} := \mathscr{F}_{/x} \times_{\mathscr{F}} \mathscr{F}_N$ of the slice $\mathscr{F}_{/x}$ consisting of those morphisms over x that are contained in $\mathscr{F}_N$. We note that $F_{/x} := (\mathscr{F}_{/x}, \mathscr{F}_{/x,N})$ is again a span pair, which is (weakly) extensive if $(\mathscr{F}, \mathscr{F}_N)$ is so. In particular we may speak of $F_{/x}$-normed monoids in $\mathscr{C}$.

Example 3.1.9. Let T be any small ∞-category, and let $\mathbb{F}[T]$ be the ∞-category obtained by freely adjoining finite coproducts to T, i.e. $\mathbb{F}[T]$ is the full subcategory of the ∞-category of presheaves spanned by finite coproducts of representables. An *orbital subcategory of* T [CLL23a, 4.2.2] is a wide subcategory $P \subseteq T$ such that $(\mathbb{F}[T], \mathbb{F}[P])$ is a span pair. In this case, $(\mathbb{F}[T], \mathbb{F}[P])$ is always extensive: indeed, pullbacks in $\mathbb{F}[T]$ are also pullbacks in $\mathsf{Fun}(T^{\text{op}}, \mathsf{Spc})$ as $\mathbb{F}[T]$ contains all representables, whence it suffices to check the compatibility axioms between coproducts and pullbacks in Spc, which is straightforward.

In particular, if T is any *orbital category* in the sense of [Nar16, 4.1] (i.e. T is orbital as a subcategory of itself), then $(\mathbb{F}[T], \mathbb{F}[T])$ is extensive. Note that for $T = \mathbf{O}_G$ the *orbit category* of G (i.e. the 1-category of finite transitive G-sets), we precisely recover Example 3.1.4.

Remark 3.1.10. If $F_T := (\mathbb{F}[T], \mathbb{F}[T])$ is the extensive span pair arising from an orbital ∞-category T, then our definition of F_T-normed monoids fits into the framework for algebraic structures defined by Segal conditions from [CH21]: We can endow $\mathsf{Span}(\mathbb{F}[T])$ with the structure of an *algebraic pattern* where the inert–active factorization system is that given by the backwards and forwards maps, and the objects of T are the elementary objects. Then a Segal $\mathsf{Span}(\mathbb{F}[T])$-object in $\mathscr{C}$ is a functor $M\colon \mathsf{Span}(\mathbb{F}[T]) \to \mathscr{C}$ such that

$$M(\textstyle\coprod_i t_i) \xrightarrow{\sim} \prod_{i=1}^n M(t_i)$$

for all $t_i \in T$, which is equivalent to M preserving finite products.

3.2 Normed ∞-categories and normed algebras

In this subsection we fix a weakly extensive span pair $F = (\mathscr{F}, \mathscr{F}_N)$. Specializing Definition 3.1.1 to Cat_∞ leads to the following definition:

Definition 3.2.1 (Bachmann)**.** An *F-normed ∞-category* is an F-normed monoid in Cat_∞, i.e. a product-preserving functor $\mathscr{C}\colon \mathsf{Span}_N(\mathscr{F}) \to \mathsf{Cat}_\infty$. We denote its contravariant functoriality by $f^*\colon \mathscr{C}(y) \to \mathscr{C}(x)$ for morphisms $f\colon x \to y$ in $\mathscr{F}$, and denote its covariant functoriality by $f_\otimes\colon \mathscr{C}(x) \to \mathscr{C}(y)$ whenever f is in $\mathscr{F}_N$.

Remark 3.2.2. When F is actually an extensive span pair, our definition of a normed ∞-category is identical to that of Bachmann [Bac22, 3.1].

Remark 3.2.3. Since the product in $\mathsf{Span}_N(\mathcal{F})$ is the coproduct in $\mathcal{F}$, a functor $\mathsf{Span}_N(\mathcal{F}) \to \mathsf{Cat}_\infty$ is an F-normed ∞-category if and only if its restriction to $\mathcal{F}^{\mathrm{op}}$ preserves finite products. We will sometimes refer to product-preserving functors $\mathcal{F}^{\mathrm{op}} \to \mathsf{Cat}_\infty$ as *$\mathcal{F}$-∞-categories*, and refer to the restriction of an F-normed ∞-category $\mathcal{C}$ to $\mathcal{F}^{\mathrm{op}}$ as the *underlying $\mathcal{F}$-∞-category* of $\mathcal{C}$. Similarly, we may sometimes refer to F-normed ∞-categories as *N-normed $\mathcal{F}$-∞-categories* whenever we wish to emphasize the collection of morphisms $\mathcal{F}_N$ along which we have norms.

Note that for $F_T = (\mathbb{F}[T], \mathbb{F}[T])$, T some orbital ∞-category, an $\mathbb{F}[T]$-∞-category is equivalently a functor $T^{\mathrm{op}} \to \mathsf{Cat}_\infty$ by the universal property of finite coproduct completion. This is the definition of a *T-∞-category* used e.g. in [BDG+16, Nar16, CLL23a].

Notation 3.2.4. Given an F-normed structure on an ∞-category $\mathcal{C}$, we will denote the corresponding cocartesian and cartesian fibrations by

$$\mathcal{C}^{\otimes} \longrightarrow \mathsf{Span}_N(\mathcal{F}), \quad \mathcal{C}_{\otimes} \longrightarrow \mathsf{Span}_N(\mathcal{F})^{\mathrm{op}}.$$

We say that a morphism in $\mathcal{C}^{\otimes}$ is *inert* if it is cocartesian over a backwards morphism in $\mathsf{Span}_N(\mathcal{F})$; similarly, a morphism in $\mathcal{C}_{\otimes}$ is *inert* if it is cartesian over a (reversed) backwards morphism in $\mathsf{Span}_N(\mathcal{F})^{\mathrm{op}}$.

Definition 3.2.5. Suppose $\mathcal{C}^{\otimes}, \mathcal{D}^{\otimes} \to \mathsf{Span}_N(\mathcal{F})$ are F-normed ∞-categories. An *F-normed functor* from $\mathcal{C}$ to $\mathcal{D}$ is a commutative triangle

$$\begin{array}{ccc} \mathcal{C}^{\otimes} & \xrightarrow{\quad\Phi\quad} & \mathcal{D}^{\otimes} \\ & \searrow \quad \swarrow & \\ & \mathsf{Span}_N(\mathcal{F}) & \end{array}$$

where Φ preserves cocartesian morphisms. We say that Φ is *lax F-normed* if it instead only preserves inert morphisms. We write

$$\mathsf{Fun}^{\mathrm{lax}}_{/\mathsf{Span}_N(\mathcal{F})}(\mathcal{C}^{\otimes}, \mathcal{D}^{\otimes}) \subseteq \mathsf{Fun}_{/\mathsf{Span}_N(\mathcal{F})}(\mathcal{C}^{\otimes}, \mathcal{D}^{\otimes})$$

for the full subcategory spanned by the lax F-normed functors.

Remark 3.2.6. In the non-parametrized case, i.e. the case $F = (\mathbb{F}, \mathbb{F})$, it follows from [BHS22, 5.1.15] that this definition of lax symmetric monoidal functors agrees with the more standard one, with $\mathbb{F}_*$ in place of $\mathsf{Span}(\mathbb{F})$.

Definition 3.2.7. An *F-normed algebra* in an F-normed ∞-category $\mathcal{C}$ is a lax F-normed functor from $*^{\otimes} = \mathsf{Span}_N(\mathcal{F})$ to $\mathcal{C}$; in other words, it is a section of the cocartesian fibration

$$\mathcal{C}^{\otimes} \longrightarrow \mathsf{Span}_N(\mathcal{F})$$

that takes backward maps in $\mathsf{Span}_N(\mathcal{F})$ to cocartesian morphisms. We write

$$\mathsf{NAlg}_F(\mathcal{C}) := \mathsf{Fun}^{\mathrm{lax}}_{/\mathsf{Span}_N(\mathcal{F})}(\mathsf{Span}_N(\mathcal{F}), \mathcal{C}^{\otimes})$$

for the ∞-category of F-normed algebras in $\mathcal{C}$.

Remark 3.2.8. By an easy extension of [BHS22, 5.2.14], our definitions of F-normed ∞-categories and lax F-normed functors are equivalent to those of Nardin and Shah [NS22] in the case where $F = F_T$ for a so-called "atomic" orbital ∞-category T. In particular, the ∞-categories of F-normed algebras are equivalent, cf. [BHS22, 5.3.17]. For extensive F, our F-normed algebras are also studied in [Bac22], as a generalization of the normed spectra introduced in [BH21, 7.1].

We end this section by considering a construction of normed structures on spans:

Construction 3.2.9. Since the functor $\mathsf{Span}\colon \mathsf{SpanPair} \to \mathsf{Cat}_\infty$ preserves limits, hence in particular finite products, any F-normed monoid in $\mathsf{SpanPair}$ gives rise to an F-normed ∞-category by applying Span pointwise. Observe that an F-normed monoid in $\mathsf{SpanPair}$ is an F-normed ∞-category

$$\mathcal{C}\colon \mathsf{Span}_N(\mathcal{F}) \longrightarrow \mathsf{Cat}_\infty$$

equipped with a subfunctor $\mathcal{C}_Q \subseteq \mathcal{C}$ such that $(\mathcal{C}(X), \mathcal{C}_Q(X))$ is a span pair for every $X \in \mathcal{F}$ and the induced functor $m_\otimes f^*\colon \mathcal{C}(X) \to \mathcal{C}(Y)$ is a map of span pairs for every morphism $X \xleftarrow{f} Z \xrightarrow{m} Y$ in $\mathsf{Span}_N(\mathcal{F})$. In this case, the composite

$$\mathsf{Span}_Q(\mathcal{C}) := \mathsf{Span} \circ (\mathcal{C}, \mathcal{C}_Q)\colon \mathsf{Span}_N(\mathcal{F}) \longrightarrow \mathsf{Cat}_\infty$$

endows $\mathsf{Span}_Q(\mathcal{C})$ with an F-normed structure inherited from that of $\mathcal{C}$.

The following result provides an explicit description of the cocartesian fibrations associated to such normed structures:

Proposition 3.2.10. *Let $p\colon \mathcal{C}_\otimes \to \mathsf{Span}_N(\mathcal{F})^{\mathrm{op}}$ be a cartesian fibration corresponding to an F-normed monoid in $\mathsf{SpanPair}$. Then the cocartesian fibration $\mathsf{Span}_Q(\mathcal{C})^{\otimes} \to \mathsf{Span}_N(\mathcal{F})$ for the induced F-normed structure on spans from Construction 3.2.9 is given by*

$$\mathsf{Span}_Q(\mathcal{C})^{\otimes} \simeq \mathsf{Span}_{Q-\mathrm{fw}}(\mathcal{C}_\otimes),$$

where $(\mathcal{C}_\otimes)_{Q-\mathrm{fw}}$ denotes the subcategory of maps that go to equivalences under p and fiberwise lie in $\mathcal{C}^{\otimes}(-)_Q$.

Proof. This is a special case of [HHLN23, 3.9]. □

3.3 Norms on product-preserving functors

In this subsection we will construct a (low-tech) version of "parametrized Day convolution" for ∞-categories of product-preserving functors. More precisely, we will show the following:

Proposition 3.3.1. *Let $\mathcal{X}$ be a cocomplete ∞-category with finite products, where the product functor preserves colimits in each variable. Suppose $F = (\mathcal{F}, \mathcal{F}_N)$ is a weakly extensive span pair, and consider an F-normed ∞-category $\mathcal{C}\colon \mathsf{Span}_N(\mathcal{F}) \to \mathsf{Cat}_\infty$ such that $\mathcal{C}(X)$ has finite products for every $X \in \mathcal{F}$ (but the morphisms in the diagram need not preserve these).*

(i) There is a functor

$$\mathbb{Q} = \mathsf{Fun}^{\times}(\mathcal{C}(-), \mathcal{X})\colon \mathsf{Span}_N(\mathcal{F}) \longrightarrow \widehat{\mathsf{Cat}}_\infty$$

obtained by left Kan extension from $\mathcal{C}$. This preserves finite products, and so defines another F-normed ∞-category.

(ii) If $\mathcal{C}^{\otimes} \to \mathsf{Span}_N(\mathcal{F})$ is the cocartesian fibration for $\mathcal{C}$, then F-normed algebras in $\mathbb{Q} = \mathsf{Fun}^{\times}(\mathcal{C}(-), \mathcal{X})$ are equivalent to functors

$$A\colon \mathcal{C}^{\otimes} \longrightarrow \mathcal{X}$$

such that

- *for every $X \in \mathcal{F}$ the restriction*

$$A_X\colon \mathcal{C}(X) \longrightarrow \mathcal{X}$$

of A to the fiber over X is a product-preserving functor,

- *and for every morphism $f\colon X \to Y$ in $\mathcal{F}$, viewed as a backward morphism in $\mathsf{Span}_N(\mathcal{F})$, the natural transformation*

$$\begin{array}{ccc} \mathcal{C}(Y) & \xrightarrow{\quad f^* \quad} & \mathcal{C}(X) \\ & \Longrightarrow & \\ {\scriptstyle A_Y} \searrow & & \swarrow {\scriptstyle A_X} \\ & \mathcal{X} & \end{array}$$

exhibits A_X as a left Kan extension of A_Y along f^*.

More precisely, $\mathsf{NAlg}_F(\mathbb{Q})$ is equivalent to the full subcategory $\mathcal{A} \subseteq \mathsf{Fun}(\mathcal{C}^{\otimes}, \mathcal{X})$ of functors that satisfy these conditions, and for every $A \in \mathcal{F}$ this equivalence fits into a commutative diagram

$$\begin{array}{ccc} \mathsf{NAlg}_F(\mathbb{Q}) & \xrightarrow{\quad \simeq \quad} & \mathcal{A}. \\ {\scriptstyle \mathrm{ev}_A} \searrow & & \swarrow {\scriptstyle \mathrm{res}} \\ & \mathsf{Fun}^{\times}(\mathcal{C}(A), \mathcal{X}) & \end{array}$$

The key input to the construction is the following observation about left Kan extensions of product-preserving functors:

Proposition 3.3.2. *Suppose $\mathscr{A}$ and $\mathscr{B}$ are small ∞-categories with finite products, and $\mathscr{C}$ is an ∞-category with small colimits and finite products such that the cartesian product preserves colimits in each variable. If $F\colon \mathscr{A} \to \mathscr{C}$ is a product-preserving functor and $g\colon \mathscr{A} \to \mathscr{B}$ is an arbitrary functor, then the left Kan extension $g_!F$ also preserves finite products. In other words, left Kan extension restricts to a functor*

$$g_!\colon \mathsf{Fun}^{\times}(\mathscr{A}, \mathscr{C}) \longrightarrow \mathsf{Fun}^{\times}(\mathscr{B}, \mathscr{C}).$$

Remark 3.3.3. For 1-categories, a version of this result apparently goes back to Lawvere's thesis [Law04]. See also for instance [Day70, Appendix 2] or [BD77] for generalizations to enriched categories and [Str14] for another variant and a historical discussion.

Proof of Proposition 3.3.2. Our assumptions guarantee that $g_!F$ is computed by the pointwise formula,

$$g_!F(b) \simeq \operatorname{colim}_{\mathscr{A}_{/b}} F.$$

In particular, $g_!F(*)$ is a colimit over $\mathscr{A} \times_{\mathscr{B}} \mathscr{B}_{/*} \simeq \mathscr{A}$; since this has a terminal object $* \to *$, we see

$$g_!F(*) \simeq F(*) \simeq *.$$

For objects $b_1, b_2 \in \mathscr{B}$, consider the functor

$$\pi_{b_1,b_2}\colon \mathscr{A}_{/b_1 \times b_2} \longrightarrow \mathscr{A}_{/b_1} \times \mathscr{A}_{/b_2}$$

given by composition with the projections $b_1 \times b_2 \to b_i$. We claim that this functor has a right adjoint $R = R_{b_1,b_2}$, given on a pair (Φ_1, Φ_2) of objects $\Phi_i := (a_i, \phi_i\colon g(a_i) \to b_i)$ in $\mathscr{A}_{/b_i}$ by $R(\Phi_1, \Phi_2) = (a_1 \times a_2, r(\phi_1, \phi_2))$, where $r(\phi_1, \phi_2)$ is defined as the composite

$$g(a_1 \times a_2) \to g(a_1) \times g(a_2) \xrightarrow{\phi_1 \times \phi_2} b_1 \times b_2.$$

To see this, observe that for an object $\Psi = (x, \psi\colon g(x) \to b_1 \times b_2)$ of $\mathscr{A}_{/b_1 \times b_2}$ the mapping space $\mathsf{Map}_{\mathscr{A}_{/b_1 \times b_2}}(\Psi, R(\Phi_1, \Phi_2))$ sits in a pullback diagram as follows:

$$\begin{array}{ccccc}
\mathsf{Map}_{\mathscr{A}_{/b_1 \times b_2}}(\Psi, R(\Phi_1, \Phi_2)) & \to & \mathsf{Map}_{\mathscr{B}_{/b_1 \times b_2}}(\psi, r(\phi_1, \phi_2)) & \longrightarrow & \{\psi\} \\
\downarrow & \lrcorner & \downarrow & \lrcorner & \downarrow \\
\mathsf{Map}_{\mathscr{A}}(x, a_1 \times a_2) & \xrightarrow{g} & \mathsf{Map}_{\mathscr{B}}(g(x), g(a_1 \times a_2)) & \xrightarrow{r(\phi_1,\phi_2)\circ -} & \mathsf{Map}_{\mathscr{B}}(g(x), b_1 \times b_2).
\end{array}$$

Under the identification of $\mathsf{Map}_{\mathscr{A}}(x, a_1 \times a_2)$ with $\mathsf{Map}_{\mathscr{A}}(x, a_1) \times \mathsf{Map}_{\mathscr{A}}(x, a_2)$ and of $\mathsf{Map}_{\mathscr{B}}(g(x), b_1 \times b_2)$ with $\mathsf{Map}_{\mathscr{B}}(g(x), b_1) \times \mathsf{Map}_{\mathscr{B}}(g(x), b_2)$, the bottom map turns into a product of the two maps

$$\mathsf{Map}_{\mathscr{A}}(x, a_i) \xrightarrow{g} \mathsf{Map}_{\mathscr{B}}(g(x), g(a_i)) \xrightarrow{\phi_i \circ -} \mathsf{Map}_{\mathscr{B}}(g(x), b_i),$$

and so by passing to fibers we obtain a natural equivalence

$$\mathsf{Map}_{\mathcal{A}_{/b_1\times b_2}}(\Psi, R(\Phi_1,\Phi_2)) \xrightarrow{\sim} \mathsf{Map}_{\mathcal{A}_{/b_1}}((x,\mathrm{pr}_1\psi),\Phi_1)\times \mathsf{Map}_{\mathcal{A}_{/b_2}}((x,\mathrm{pr}_2\psi),\Phi_2).$$

Since the target is canonically identified with $\mathsf{Map}_{\mathcal{A}_{/b_1}\times\mathcal{A}_{/b_2}}(\pi_{b_1,b_2}\Psi,(\Phi_1,\Phi_2))$, this shows that R_{b_1,b_2} is the desired right adjoint.

Since right adjoints are cofinal, composition with R_{b_1,b_2} therefore induces an equivalence

$$g_!F(b_1)\times g_!F(b_2) \simeq \mathrm{colim}_{(a,a')\in\mathcal{A}_{/b_1}\times\mathcal{A}_{/b_2}} F(a\times a') \longrightarrow \mathrm{colim}_{x\in\mathcal{A}_{/b_1\times b_2}} F(x)\simeq g_!F(b_1\times b_2).$$

Moreover, these right adjoints are compatible with composition in $\mathcal{B}$, so for maps $b_1\to c_1, b_2\to c_2$ we get a commutative square

$$\begin{array}{ccc} g_!F(b_1)\times g_!F(b_2) & \xrightarrow{\sim} & g_!F(b_1\times b_2) \\ \downarrow & & \downarrow \\ g_!F(c_1)\times g_!F(c_2) & \xrightarrow{\sim} & g_!F(c_1\times c_2). \end{array}$$

Taking $c_1 = b_1$ and $c_2 = *$, we see in particular that projection to $g_!F(b_1)$ on the left corresponds to composition with $b_1\times b_2\to b_1$ on the right, so that the canonical map $g_!F(b_1\times b_2)\to g_!F(b_1)\times g_!F(b_2)$ is an equivalence. In other words, the functor $g_!F$ is product-preserving, as required. □

Lemma 3.3.4. *Suppose $\mathcal{A}_1,\ldots,\mathcal{A}_n$ and $\mathcal{B}$ are ∞-categories with finite products. If $\mathcal{A} := \prod_i \mathcal{A}_i$, then left Kan extension along the projections $\pi_i\colon \mathcal{A}\to\mathcal{A}_i$ gives an equivalence*

$$\mathsf{Fun}^{\times}(\mathcal{A},\mathcal{B}) \xrightarrow{\sim} \prod_i \mathsf{Fun}^{\times}(\mathcal{A}_i,\mathcal{B}),$$

with inverse given by

$$(F_i\colon \mathcal{A}_i\longrightarrow\mathcal{B}) \;\mapsto\; \left(\prod_i F_i\circ\pi_i\colon \mathcal{A}\longrightarrow\mathcal{B}\right)$$

Proof. For $i=0$ we indeed have $\mathsf{Fun}^{\times}(*,\mathcal{B})\simeq *$ as the only product-preserving functor is the one constant at the terminal object. Suppose therefore that $i>1$. The pointwise left Kan extension of $F\colon\mathcal{A}\to\mathcal{B}$ along π_i, if it exists, is given at $x\in\mathcal{A}_i$ by taking a colimit over

$$\mathcal{A}_{/x}\simeq \mathcal{A}_{i/x}\times\prod_{j\neq i}\mathcal{A}_j$$

This has a terminal object, so the colimit (and hence the pointwise Kan extension) always exists, and is given by

$$(\pi_{i,!}F)(x)\simeq F(*,\ldots,*,x,*,\ldots,*).$$

The functor we claim is an equivalence is the composite

$$\mathsf{Fun}^{\times}(\mathscr{A},\mathscr{B}) \longrightarrow \prod_i \mathsf{Fun}^{\times}(\mathscr{A},\mathscr{B}) \xrightarrow{\prod_i \pi_{i,!}} \prod_i \mathsf{Fun}^{\times}(\mathscr{A}_i,\mathscr{B}).$$

Since $\mathsf{Fun}^{\times}(\mathscr{A},\mathscr{B})$ has finite products (computed pointwise), this functor has a right adjoint, given by

$$\prod_i \mathsf{Fun}^{\times}(\mathscr{A}_i,\mathscr{B}) \xrightarrow{\prod \pi_i^*} \prod_i \mathsf{Fun}^{\times}(\mathscr{A},\mathscr{B}) \xrightarrow{\times} \mathsf{Fun}^{\times}(\mathscr{A},\mathscr{B}).$$

To see that this adjunction is in fact an equivalence, it suffices to observe that for $F_i \in \mathsf{Fun}^{\times}(\mathscr{A}_i,\mathscr{B})$ we have

$$\Big(\pi_{j,!}\Big(\prod_i F_i \circ \pi_i\Big)\Big)(x) \simeq F_j(x) \times \prod_{i\neq j} F_i(*) \simeq F_j(x)$$

and that for $F \in \mathsf{Fun}^{\times}(\mathscr{A},\mathscr{B})$ we have

$$F(x_1,\ldots,x_n) \xrightarrow{\sim} \prod_i (\pi_{i,!}F)(x_i),$$

since $(x_1,\ldots,x_n)$ is the finite product

$$(x_1,*,\cdots *) \times (*,x_2,*,\ldots,*) \times \cdots (*,\ldots,*,x_n)$$

in $\mathscr{A}$. ◻

Remark 3.3.5. Let $\mathscr{R}$ be any collection of diagram shapes containing both the empty set and the two-point set. Then the same argument shows that the categories of $\mathscr{R}$-shaped limit preserving functors satisfy $\mathsf{Fun}^{\mathscr{R}\text{-lim}}(\prod_{i=1}^n \mathscr{A}_i,\mathscr{B}) \simeq \prod_{i=1}^n \mathsf{Fun}^{\mathscr{R}\text{-lim}}(\mathscr{A}_i,\mathscr{B})$.

We now come to our main construction:

Construction 3.3.6. Let $\mathfrak{X}$ be a cocomplete ∞-category with finite products, such that the cartesian product preserves colimits in each variable, and let $F\colon \mathscr{I} \to \mathsf{Cat}_\infty$ be a functor such that $F(i)$ has finite products for all $i \in \mathscr{I}$ (but these are not necessarily preserved by the morphisms in the diagram).

Let $p\colon \mathscr{E} \to \mathscr{I}$ be the cartesian fibration for the functor

$$\mathsf{Fun}(F(-),\mathfrak{X})\colon \mathscr{I}^{\mathrm{op}} \longrightarrow \widehat{\mathsf{Cat}}_\infty,$$

and note that by [GHN17, 7.3] there is a natural equivalence

$$\mathsf{Fun}_{/\mathscr{I}}(\mathscr{K},\mathscr{E}) \simeq \mathsf{Fun}(\mathscr{K} \times_{\mathscr{I}} \mathscr{F},\mathfrak{X}), \tag{7}$$

where $\mathscr{F} \to \mathscr{I}$ is the cocartesian fibration for F. Here p is also a cocartesian fibration, since we can left Kan extend functors to $\mathfrak{X}$. Moreover, if we define $\mathscr{E}'$

as the full subcategory containing the functors $F(i) \to \mathfrak{X}$ that preserve products for all i, then Proposition 3.3.2 implies that $\mathscr{E}' \to \mathscr{I}$ is again a cocartesian fibration. Note that for $f: i \to j$ in $\mathscr{I}$, a morphism ϕ in $\mathscr{E}$ over f corresponds under the equivalence (7) to a functor $[1] \times_{\mathscr{I}} \mathscr{F} \to \mathfrak{X}$. Here the source is the cocartesian fibration over $[1]$ encoding the functor $F(f): F(i) \to F(j)$ and so can be described as the pushout $F(i) \times [1] \amalg_{F(i)\times\{1\}} F(j)$, see [GHN17, 3.1]. We can thus identify the morphism ϕ with a natural transformation

$$\begin{array}{ccc} F(i) & \xrightarrow{F(f)} & F(j) \\ & \searrow \;\Longrightarrow\; \swarrow & \\ & \mathfrak{X}, & \end{array}$$

and ϕ is a cocartesian morphism if and only if this diagram exhibits $F(j) \to \mathfrak{X}$ as a left Kan extension of $F(i) \to \mathfrak{X}$ along $F(f)$.

Proof of Proposition 3.3.1. To prove that $\mathbb{Q}$ is F-normed we must show that given a finite coproduct $X \simeq \coprod_i X_i$ in $\mathscr{F}$, with $\iota_j: X_j \to X$ the summand inclusions, the functor

$$(\pi_{j,!})_j : \mathsf{Fun}^\times(\mathscr{C}(X), \mathfrak{X}) \longrightarrow \prod_j \mathsf{Fun}^\times(\mathscr{C}(X_j), \mathfrak{X}),$$

where $\pi_j := \mathscr{C}(\iota_j)$, is an equivalence. This is the content of Lemma 3.3.4.

Part (ii) follows immediately from Construction 3.3.6 specialized to $\mathscr{I} = \mathsf{Span}_N(\mathscr{F})$: note that the straightening of the cocartesian fibration $\mathscr{E} \to \mathscr{I}$ dicussed there agrees by definition with the functor $X \mapsto \mathsf{Fun}(\mathscr{C}(X), \mathfrak{X})$ with functoriality via left Kan extension, so that the cocartesian subfibration $\mathscr{E}' \to \mathscr{I}$ classifies the functor $\mathsf{Fun}^\times(\mathscr{C}(-), \mathfrak{X})$ in question. □

Observation 3.3.7. In the situation above, suppose the functor $f^*: \mathscr{C}(Y) \to \mathscr{C}(X)$ has a right adjoint f_* for every backwards map f. Then the condition for $A: \mathscr{C}^\otimes \to \mathfrak{X}$ to define an F-normed algebra in $\mathbb{Q}$ can be rephrased as requiring an equivalence

$$A_X \simeq A_Y \circ f_*.$$

In this case $\mathscr{C}^\otimes$ also has *cartesian* morphisms over backwards maps, and we can phrase this condition more precisely as: If $\bar{X}$ is in $\mathscr{C}^\otimes_X$ and $\phi: \bar{Y} \to \bar{X}$ is cartesian over a backwards map in $\mathsf{Span}_N(\mathscr{F})$, then $A(\phi)$ is an equivalence.

In the special case $F = (\mathbb{F}, \mathbb{F})$, the resulting normed structure on $\mathsf{Fun}^\times(\mathscr{C}, \mathfrak{X})$ corresponds by Example 3.1.6 to a symmetric monoidal structure. We will now compare it to the Day convolution monoidal structure:

Proposition 3.3.8. *Let $\mathfrak{X}$ be a cocomplete ∞-category with finite products, where the product functor preserves colimits in each variable. Suppose $\mathscr{C}: \mathsf{Span}(\mathbb{F}) \to \mathsf{Cat}_\infty$ is a symmetric monoidal ∞-category whose underlying ∞-category has finite products.*

- *The symmetric monoidal structure on* $\mathsf{Fun}^{\times}(\mathcal{C},\mathcal{X})$ *from Proposition 3.3.1 is a full symmetric monoidal subcategory of the Day convolution on* $\mathsf{Fun}(\mathcal{C},\mathcal{X})$.
- *If* $\mathcal{X}$ *is presentable and the tensor product on* $\mathcal{C}$ *preserves finite products in each variable, it is moreover a symmetric monoidal localization.*

The proof will require some preparations.

Lemma 3.3.9. *Let* $\mathcal{C},\mathcal{D}\to\mathcal{I}$ *be cocartesian fibrations, and let* $F\colon\mathcal{C}\to\mathcal{D}$ *be a functor over* $\mathcal{I}$. *Then the following are equivalent:*

(i) F *preserves cocartesian edges.*

(ii) For every cocartesian edge $[1]\to\mathcal{C}$ *the composite* $[1]\to\mathcal{D}$ *is the relative left Kan extension (over* $\mathcal{I}$*) of its restriction to* 0.

(iii) For every $i\in\mathcal{I}$ *and every* $\mathcal{I}_{i/}\to\mathcal{C}$ *over* $\mathcal{I}$ *landing in the subcategory of cocartesian edges, the composite* $\mathcal{I}_{i/}\to\mathcal{D}$ *is relatively left Kan extended from* $\mathrm{id}_i\in\mathcal{I}_{i/}$.

Proof. Recall that if $\mathcal{J}\to\mathcal{I}$ is arbitrary and $\mathcal{J}$ has an initial object $\emptyset$, then the relative left Kan extension along $\{\emptyset\}\hookrightarrow\mathcal{J}$ exists for every cocartesian fibration $\mathcal{E}\to\mathcal{I}$, and $\mathcal{J}\to\mathcal{E}$ is relatively left Kan extended if and only if it factors through cocartesian edges [Lur24, Tag 043G]. The equivalence between (1) and (2) follows immediately, while for the equivalence between (1) and (3) it suffices to observe in addition that every cocartesian edge $x\to y$ of $\mathcal{C}$ is contained in the image of some cocartesian $\mathcal{I}_{i/}\to\mathcal{C}$: namely, if i is the image of x, then the relative left Kan extension of x along $\{\emptyset\}\hookrightarrow\mathcal{I}_{i/}$ has the required properties. □

Proposition 3.3.10. *Let* $\mathcal{C}\colon\mathsf{Span}(\mathbb{F})\to\mathsf{Cat}_\infty$ *be a symmetric monoidal* ∞*-category, let* $\mathcal{X}$ *be a cocomplete category with finite products such that the product preserves colimits in each variable, and let* $\mathcal{E}'\to\mathsf{Span}(\mathbb{F})$ *denote the cocartesian fibration classifying the functor* $\mathsf{Fun}^{\times}(\mathcal{C}(-),\mathcal{X})$ *with functoriality via left Kan extension.*

If $\mathcal{O}^{\otimes}\to\mathsf{Span}(\mathbb{F})$ *is any symmetric monoidal* ∞*-category, then* $\mathcal{C}^{\otimes}\times_{\mathsf{Span}(\mathbb{F})}\mathcal{O}^{\otimes}$ *has finite products, and a functor* $\mathcal{O}^{\otimes}\to\mathcal{E}'$ *over* $\mathsf{Span}(\mathbb{F})$ *is lax symmetric monoidal if and only if the functor* $\tilde{F}\colon\mathcal{C}^{\otimes}\times_{\mathsf{Span}(\mathbb{F})}\mathcal{O}^{\otimes}\to\mathcal{X}$ *associated to* F *via (7) preserves finite products.*

Proof. We first recall from [Hau23, 2.2.6] that $\mathcal{C}^{\otimes}$ and $\mathcal{O}^{\otimes}$ have finite products and that the maps $\mathcal{C}^{\otimes}\to\mathsf{Span}(\mathbb{F})$ and $\mathcal{O}^{\otimes}\to\mathsf{Span}(\mathbb{F})$ preserve them; thus, $\mathcal{C}^{\otimes}\times_{\mathsf{Span}(\mathbb{F})}\mathcal{O}^{\otimes}$ again has finite products, which are computed componentwise. The cited reference moreover shows that any $X\in\mathcal{O}_{\mathbf{n}}$ is the product of its cocartesian pushforwards along the backwards maps $\mathbf{n}\leftarrow\mathbf{1}=\mathbf{1}$; thus, we see that a functor $\mathcal{C}^{\otimes}\times_{\mathsf{Span}(\mathbb{F})}\mathcal{O}^{\otimes}\to\mathcal{X}$ preserves products if and only if its restriction to $\mathcal{C}^{\otimes}\times_{\mathsf{Span}(\mathbb{F})}(\mathbb{F}_{/\mathbf{n}})^{\mathrm{op}}$ does so for every map $(\mathbb{F}_{/\mathbf{n}})^{\mathrm{op}}\to\mathcal{O}^{\otimes}$ over $\mathsf{Span}(\mathbb{F})$ landing in cocartesian edges.

Write now $\mathcal{E}\to\mathsf{Span}(\mathbb{F})$ for the cocartesian fibration from Construction 3.3.6 classifying $\mathsf{Fun}(\mathcal{C}(-),\mathcal{X})$, of which $\mathcal{E}'\to\mathsf{Span}(\mathbb{F})$ is a subfibration.

We then have for every $\mathbf{n} \in \mathbb{F}$ and $(\mathbb{F}_{/\mathbf{n}})^{\mathrm{op}} \to \mathcal{O}^{\otimes}$ over $\mathsf{Span}(\mathbb{F})$ a commutative diagram

$$\begin{array}{ccc} \mathsf{Fun}_{/\mathsf{Span}(\mathbb{F})}(\mathcal{O}^{\otimes}, \mathcal{E}) & \xrightarrow{\sim} & \mathsf{Fun}(\mathcal{C}^{\otimes} \times_{\mathsf{Span}(\mathbb{F})} \mathcal{O}^{\otimes}, \mathcal{X}) \\ \downarrow & & \downarrow \\ \mathsf{Fun}_{/\mathsf{Span}(\mathbb{F})}((\mathbb{F}_{/\mathbf{n}})^{\mathrm{op}}, \mathcal{E}) & \xrightarrow{\sim} & \mathsf{Fun}(\mathcal{C}^{\otimes} \times_{\mathsf{Span}(\mathbb{F})} (\mathbb{F}_{/\mathbf{n}})^{\mathrm{op}}, \mathcal{X}) \\ \downarrow & & \downarrow \\ \mathsf{Fun}(\{O\}, \mathsf{Fun}(\mathcal{C}_{\mathbf{n}}, \mathcal{X})) & \xrightarrow{\sim} & \mathsf{Fun}(\underbrace{\mathcal{C}^{\otimes} \times_{\mathsf{Span}(\mathbb{F})} \{O\}}_{=\mathcal{C}_{\mathbf{n}}}, \mathcal{X}) \end{array} \tag{8}$$

where the horizontal equivalences are as in Construction 3.3.6 and the vertical maps are the restrictions. By the previous lemma applied to $\mathcal{I} = \mathbb{F}^{\mathrm{op}}$, $F\colon \mathcal{O}^{\otimes} \to \mathcal{E}$ preserves inert edges if and only if restriction to $(\mathbb{F}_{/\mathbf{n}})^{\mathrm{op}}$ is contained in the image of the left adjoint of the lower left vertical map for every $(\mathbb{F}_{/\mathbf{n}})^{\mathrm{op}} \to \mathcal{O}^{\otimes}$ factoring through cocartesian edges. It follows formally from commutativity of (8) that this is equivalent to the restriction of the corresponding functor $\tilde{F}$ to $\mathcal{C}^{\otimes} \times_{\mathsf{Span}(\mathbb{F})} (\mathbb{F}_{/\mathbf{n}})^{\mathrm{op}}$ being left Kan extended from $\mathcal{C}_{\mathbf{n}}$; it remains to show that if F factors through $\mathcal{E}' \subseteq \mathcal{E}$ (i.e. if the restriction of $\tilde{F}$ to $\mathcal{C}^{\otimes} \times_{\mathsf{Span}(\mathbb{F})} \{P\}$ preserves products for every $P \in \mathcal{O}^{\otimes}$), then the latter condition is in turn equivalent to the restriction of $\tilde{F}$ to $\mathcal{C}^{\otimes} \times_{\mathsf{Span}(\mathbb{F})} (\mathbb{F}_{/\mathbf{n}})^{\mathrm{op}} \to \mathcal{X}$ preserving products.

Proposition 3.3.2 shows that the left Kan extension of any product-preserving functor $\mathcal{C}_{\mathbf{n}} \to \mathcal{X}$ to $\mathcal{C}^{\otimes} \times_{\mathsf{Span}(\mathbb{F})} (\mathbb{F}_{/\mathbf{n}})^{\mathrm{op}}$ is again product-preserving, so the above condition is indeed sufficient for $\tilde{F}$ to preserve products. To see that it is also necessary, it will suffice to show that any product-preserving functor $G\colon \mathcal{C}^{\otimes} \times_{\mathsf{Span}(\mathbb{F})} (\mathbb{F}_{/\mathbf{n}})^{\mathrm{op}} \to \mathcal{X}$ whose restriction to $\mathcal{C}_{\mathbf{n}}$ again preserves products is left Kan extended from its restriction to $\mathcal{C}_{\mathbf{n}}$.

If we let $j\colon \mathcal{C}_{\mathbf{n}} \hookrightarrow \mathcal{C}^{\otimes} \times_{\mathsf{Span}(\mathbb{F})} (\mathbb{F}_{/\mathbf{n}})^{\mathrm{op}}$ denote the inclusion, then the counit $j_! j^* G \to G$ is an equivalence for any $(X, \mathrm{id}_n) \in \mathcal{C}^{\otimes} \times_{\mathsf{Span}(\mathbb{F})} (\mathbb{F}_{/\mathbf{n}})^{\mathrm{op}}$ by full faithfulness of j. We claim that it is in fact also an equivalence for every $(X, i\colon \mathbf{1} \to \mathbf{n})$; with this established, the claim will follow as both G (by assumption) and $j_! j^* G$ (by the above) preserve products and every object of $\mathcal{C}^{\otimes} \times_{\mathsf{Span}(\mathbb{F})} (\mathbb{F}_{/\mathbf{n}})^{\mathrm{op}}$ decomposes as a finite product of objects $(X, \mathbf{1} \to \mathbf{n})$.

To prove the claim, note that for any $X_1, \ldots, X_n \in \mathcal{C}_{\mathbf{1}}$

$$\mathcal{C}_{\mathbf{n}} \ni (X_1, \ldots, X_n; \mathrm{id}_{\mathbf{n}}) \simeq \prod_{k=1}^{n} (X_k, k\colon \mathbf{1} \longrightarrow \mathbf{n});$$

thus, the product of the counits $j_! j^* G(X_k, k\colon \mathbf{1} \to \mathbf{n}) \to G(X_k, k\colon \mathbf{1} \to \mathbf{n})$ is an equivalence as G and $j_! j^* G$ preserve products. Specializing to $X_k = *$ for $k \neq i$, it will therefore suffice that $G(*, k\colon \mathbf{1} \to \mathbf{n}) \simeq * \simeq j_! j^* G(*, k\colon \mathbf{1} \to \mathbf{n})$ for every $1 \leq k \leq n$. For this, we further set $X_i = *$ to see that

$$\prod_{k=1}^{n} G(*, k\colon \mathbf{1} \longrightarrow \mathbf{n}) \simeq G(*, \mathrm{id}_{\mathbf{n}}) \simeq j_! j^* G(*, \mathrm{id}_{\mathbf{n}}) \simeq \prod_{k=1}^{n} j_! j^* G(*, k\colon \mathbf{1} \longrightarrow \mathbf{n}).$$

As the restriction of G to $\mathcal{C}_{\mathbf{n}}$ preserves finite products, $G(*, \mathrm{id}_{\mathbf{n}})$ is terminal; since a product is terminal if and only if all of its factors are, this completes the proof of the claim and hence of the proposition. □

Proof of Proposition 3.3.8. Recall first that the Day convolution of $F, G\colon \mathcal{C} \to \mathcal{X}$ is given by the left Kan extension of

$$\mathcal{C} \times \mathcal{C} \xrightarrow{F\times G} \mathcal{X} \times \mathcal{X} \xrightarrow{\prod} \mathcal{X} \tag{9}$$

along $\otimes\colon \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ [Lur17, 2.2.6.17]. If F and G preserve products, so does (9), whence so does the Day convolution by Proposition 3.3.2. On the other hand, the unit is given by the left Kan extension of $*$ along $\{\mathbb{1}\} \hookrightarrow \mathcal{C}$, and the same argument shows that this is again product preserving, i.e. the Day convolution structure indeed restricts to $\mathsf{Fun}^{\times}(\mathcal{C}, \mathcal{X})$. Moreover, we saw in [CHLL24, 3.3.4] that this is also a symmetric monoidal localization when $\mathcal{X}$ is presentable and the tensor product on $\mathcal{C}$ preserves products in each variable.

It remains to compare this symmetric monoidal structure to the one above, for which we will show that both represent the same functor in the ∞-category of symmetric monoidal ∞-categories and *lax* symmetric monoidal functors.

For this we first recall that Day convolution is defined in such a way that lax symmetric monoidal functors $\mathcal{O}^{\otimes} \to \mathsf{Fun}(\mathcal{C}, \mathcal{X})^{\otimes}_{\mathrm{Day}}$ correspond bijectively to lax symmetric monoidal functors $\mathcal{C}^{\otimes} \times_{\mathsf{Span}(\mathbb{F})} \mathcal{O}^{\otimes} \to \mathcal{X}^{\times}$, which are in turn identified with product-preserving functors $\mathcal{C}^{\otimes} \times_{\mathsf{Span}(\mathbb{F})} \mathcal{O}^{\otimes} \to \mathcal{X}$ [CHLL24, 2.4.5 and 2.4.6]. Thus, functors into the restricted Day convolution on $\mathsf{Fun}^{\times}(\mathcal{C}, \mathcal{X})$ correspond bijectively to product-preserving functors $\mathcal{C}^{\otimes} \times_{\mathsf{Span}(\mathbb{F})} \mathcal{O}^{\otimes} \to \mathcal{X}$ such that in addition the restriction $\mathcal{C}_{\mathbf{n}} \simeq \mathcal{C}^{\otimes} \times_{\mathsf{Span}(\mathbb{F})} \{O\} \to \mathcal{X}$ preserves products for all $n \geq 0$, $O \in \mathcal{O}_{\mathbf{n}}$.

On the other hand, we have seen in Construction 3.3.6 that functors $F\colon \mathcal{O}^{\otimes} \to \mathsf{Fun}^{\times}(\mathcal{C}, \mathcal{X})^{\otimes}$ over $\mathsf{Span}(\mathbb{F})$ correspond to functors

$$\tilde{F}\colon \mathcal{C}^{\otimes} \times_{\mathsf{Span}(\mathbb{F})} \mathcal{O}^{\otimes} \longrightarrow \mathcal{X} \tag{10}$$

that preserve products when restricted to each $\mathcal{C}^{\otimes} \times_{\mathsf{Span}(\mathbb{F})} \{O\}$, and Proposition 3.3.10 shows that such a functor F is indeed lax symmetric monoidal if and only if $\tilde{F}$ preserves finite products. □

3.4 The cartesian normed structure on $\mathcal{F}$

Consider an extensive ∞-category $\mathcal{F}$ with pullbacks, taken to be fixed throughout this subsection. We will see that we may equip $\mathcal{F}$ with a "cartesian" normed structure whenever $\mathcal{F}$ is suitably locally cartesian closed.

Notation 3.4.1. We define a parametrized version $\underline{\mathcal{F}}$ of $\mathcal{F}$ as the functor

$$\underline{\mathcal{F}}\colon \mathcal{F}^{\mathrm{op}} \to \mathsf{Cat}_{\infty}, \quad X \mapsto \mathcal{F}_{/X},$$

with functoriality coming from pullbacks. Since $\mathcal{F}$ is extensive, this functor preserves products, and hence defines an $\mathcal{F}$-∞-category.

Definition 3.4.2. Given a weakly extensive subcategory $\mathcal{F}_N \subseteq \mathcal{F}$, we say that $\mathcal{F}$ is *N-locally cartesian closed* if the functor $f^*\colon \mathcal{F}_{/Y} \to \mathcal{F}_{/X}$ given by pullback along $f\colon X \to Y$ in $\mathcal{F}_N$ has a right adjoint f_*.

Proposition 3.4.3. *Let $\mathcal{F}_N \subseteq \mathcal{F}$ be a weakly extensive subcategory and suppose $\mathcal{F}$ is N-locally cartesian closed. Then the following hold:*

- *The pair $(\mathsf{Ar}(\mathcal{F}), \mathsf{Ar}(\mathcal{F})_{N-\mathrm{pb}})$ is a span pair, where $\mathsf{Ar}(\mathcal{F})_{N-\mathrm{pb}}$ consists of the pullback squares along morphisms in $\mathcal{F}_N$.*
- *The functor $\mathrm{ev}_1\colon \mathsf{Ar}(\mathcal{F}) \to \mathcal{F}$ is a morphism of span pairs.*
- *The functor*

$$\mathsf{Span}(\mathrm{ev}_1)^{\mathrm{op}}\colon \mathsf{Span}_{N-\mathrm{pb}}(\mathsf{Ar}(\mathcal{F}))^{\mathrm{op}} \longrightarrow \mathsf{Span}_N(\mathcal{F})^{\mathrm{op}}$$

is the cartesian fibration for an N-normed structure on $\underline{\mathcal{F}}$.

Proof. Consider the cocartesian fibration

$$\mathrm{ev}_1\colon \mathsf{Ar}(\mathcal{F}) \longrightarrow \mathcal{F}$$

classified by the functor $\mathcal{F}_{/(-)}\colon \mathcal{F} \to \mathsf{Cat}_\infty$, with functoriality given by composition. By assumption we have right adjoints (given by pullback) for morphisms in $\mathcal{F}_N$, and by unpacking the definitions and applying the pasting lemma for pullbacks we see that these satisfy base change. Applying Proposition 2.1.6 to this situation, we obtain the first two bullet points, and we get that $\mathsf{Span}(\mathrm{ev}_1)^{\mathrm{op}}$ is a cocartesian fibration. To see that it is also a cartesian fibration, it suffices by [Lur09, 5.2.2.4$^{\mathrm{op}}$] to show that it is a locally cartesian fibration, which we can check separately over $\mathcal{F}$ and $\mathcal{F}_N^{\mathrm{op}}$. Over $\mathcal{F}_N$ we get the cocartesian fibration for the functor $\mathcal{F}_{/(-)}\colon \mathcal{F}_N^{\mathrm{op}} \to \mathsf{Cat}_\infty$, with functoriality given by pullback; since these pullback functors have right adjoints due to N-locally cartesian closedness of $\mathcal{F}$, it is also a cartesian fibration over $\mathcal{F}_N^{\mathrm{op}}$. On the other hand, over $\mathcal{F}$ we get the functor $\mathrm{ev}_1\colon \mathsf{Ar}(\mathcal{F}) \to \mathcal{F}$. Since this is the cartesian fibration for $\underline{\mathcal{F}}$, we indeed get the cartesian fibration for an F-normed structure on $\underline{\mathcal{F}}$. □

Notation 3.4.4. In the context of Proposition 3.4.3, we write

$$\underline{\mathcal{F}}_\times \coloneqq \mathsf{Span}_{N-\mathrm{pb}}(\mathsf{Ar}(\mathcal{F}))^{\mathrm{op}}$$

and refer to it as the *cartesian* normed structure on $\underline{\mathcal{F}}$. In the non-parametrized case, this construction indeed gives the cartesian fibration for the cartesian symmetric monoidal structure on $\mathbb{F}$ by [CHLL24, 3.1.4]. We expect that our construction more generally agrees with [NS22, 2.4.1] whenever the two frameworks overlap; however, as this won't be relevant for the purposes of this paper, we will not prove this here.

4 Normed rings

In this section, we introduce the notion of a *normed ring* and show it may equivalently be encoded as a *space-valued Tambara functor*.

4.1 Normed semirings

We want to consider notions of normed semirings where we have two potentially different families of ("additive" and "multiplicative") norms, generalizing the addition and multiplication operations that exist in an ordinary semiring. To capture such structures, we introduce the following definition:

Definition 4.1.1. A *semiring context* $F = (\mathcal{F}, \mathcal{F}_M, \mathcal{F}_A)$ consists of an extensive ∞-category $\mathcal{F}$ together with two weakly extensive subcategories $\mathcal{F}_M$ and $\mathcal{F}_A$ such that:

(1) $\mathcal{F}$ has pullbacks.

(2) For $m\colon X \to Y$ in $\mathcal{F}_M$, the pullback functor $m^*\colon \mathcal{F}_{/Y} \to \mathcal{F}_{/X}$ has a right adjoint $m_*\colon \mathcal{F}_{/X} \to \mathcal{F}_{/Y}$ which preserves morphisms whose image in $\mathcal{F}$ lies in $\mathcal{F}_A$.

We write $F_M := (\mathcal{F}, \mathcal{F}_M)$ and $F_A := (\mathcal{F}, \mathcal{F}_A)$ for the resulting two weakly extensive span pairs.

Observation 4.1.2. Every semiring context is a bispan triple:

- The Beck–Chevalley condition for the functors m_* is automatically satisfied, since it may be checked after passing to left adjoints.
- For $m\colon X \to Y$ in $\mathcal{F}_M$, the functor $m_*\colon \mathcal{F}_{/X} \to \mathcal{F}_{/Y}$ preserves terminal objects, hence it sends $\mathcal{F}^A_{/X}$ into $\mathcal{F}^A_{/Y}$.

Example 4.1.3. When $\mathcal{F}_A = \mathcal{F}^{\simeq}$, the triple $(\mathcal{F}, \mathcal{F}_M, \mathcal{F}^{\simeq})$ is a semiring context if and only if $\mathcal{F}$ is extensive, admits pullbacks, and is M-locally cartesian closed, in the sense of Definition 3.4.2.

Example 4.1.4. Let $\mathcal{F}$ be an extensive ∞-category that is locally cartesian closed. Then the triple $(\mathcal{F}, \mathcal{F}, \mathcal{F})$ is a semiring context.

Example 4.1.5. For a finite group G, the category $\mathbb{F}_G$ of finite G-sets is extensive and locally cartesian closed, so that the triple $(\mathbb{F}_G, \mathbb{F}_G, \mathbb{F}_G)$ is a semiring context. More generally we obtain a semiring context $(\mathbb{F}_G, I, \mathbb{F}_G)$ for every weakly extensive subcategory $I \subseteq \mathbb{F}_G$.

We fix a semiring context $F = (\mathcal{F}, \mathcal{F}_M, \mathcal{F}_A)$. Our goal in the rest of this subsection is to construct the ∞-category $\mathsf{NRig}_F(\mathcal{X})$ of *F-normed semirings in $\mathcal{X}$* for suitable choices of ∞-categories $\mathcal{X}$. We start by constructing a certain F_M-normed ∞-category $\mathsf{Span}_A(\underline{\mathcal{F}})$ of spans in $\mathcal{F}$.

Construction 4.1.6. As $\mathcal{F}$ admits pullbacks, the evaluation map $\mathrm{ev}_1\colon \mathsf{Ar}(\mathcal{F}) \to \mathcal{F}$ is a cartesian fibration, classifying the functor $\underline{\mathcal{F}}\colon \mathcal{F}^{\mathrm{op}} \to \mathsf{Cat}_\infty$ from Notation 3.4.1. Since morphisms in $\mathcal{F}_A$ are closed under base change, we obtain a functor

$$\mathcal{F}^{\mathrm{op}} \longrightarrow \mathsf{SpanPair}, \qquad X \mapsto (\mathcal{F}_{/X}, \mathcal{F}_{/X,A})$$

where $(\mathcal{F}_{/X}, \mathcal{F}_{/X,A})$ is the span pair from Example 3.1.8; we define the $\mathcal{F}$-∞-category $\mathsf{Span}_A(\underline{\mathcal{F}})$ by composing with the functor $\mathsf{Span}\colon \mathsf{SpanPair} \to \mathsf{Cat}_\infty$. Since limits in $\mathsf{SpanPair}$ are computed in Cat_∞ and $\mathsf{Span}(-)$ preserves limits, this is indeed an $\mathcal{F}$-∞-category.

Lemma 4.1.7. *The F_M-normed ∞-category $\underline{\mathcal{F}}$ from Proposition 3.4.3 induces, via Construction 3.2.9, an F_M-normed structure on $\mathsf{Span}_A(\underline{\mathcal{F}})$.*

Proof. Equipping each $\mathcal{F}_{/X}$ with the span pair structure $(\mathcal{F}_{/X}, \mathcal{F}_{/X,A})$ from Construction 4.1.6, the functors $m_* f^*\colon \mathcal{F}_{/X} \to \mathcal{F}_{/Y}$ are morphisms of span pairs by our assumptions on F, hence we obtain an F_M-normed ∞-category $\mathsf{Span}_A(\underline{\mathcal{F}})^{\otimes}$ using Construction 3.2.9. □

Definition 4.1.8. Let $\mathcal{X}$ be a cocomplete ∞-category with finite products, such that the cartesian product preserves colimits in each variable. We define $\underline{\mathsf{NMon}}_{F_A}(\mathcal{X})$ to be the F_M-normed ∞-category $\underline{\mathsf{Fun}}^{\times}(\mathsf{Span}_A(\underline{\mathcal{F}}), \mathcal{X})$ obtained by applying Proposition 3.3.1 to the F_M-normed structure on $\mathsf{Span}_A(\underline{\mathcal{F}})$ from Construction 4.1.6.

Note that the value of $\underline{\mathsf{NMon}}_{F_A}(\mathcal{X})$ at $X \in \mathcal{F}$ is the ∞-category of $(\mathcal{F}_{/X}, \mathcal{F}_{/X,A})$-normed monoids in $\mathcal{X}$.

Example 4.1.9. Combining Proposition 3.3.8 with [CHLL24, 3.3.5], we see that when $\mathcal{X}$ is a cartesian closed presentable ∞-category, then the symmetric monoidal structure on $\mathsf{NMon}_{\mathbb{F}}(\mathcal{X}) \simeq \mathsf{CMon}(\mathcal{X})$ from Definition 4.1.8 agrees with the "standard" one constructed in [GGN15].

Remark 4.1.10. Let $f\colon X \to Y$ be any map in $\mathcal{F}$. By [BH21, C.21(2)], the adjunction $f_!\colon \mathcal{F}_{/X} \rightleftarrows \mathcal{F}_{/Y} : f^*$ induces a "wrong way" adjunction

$$f^*\colon \mathsf{Span}_A(\mathcal{F}_{/Y}) \rightleftarrows \mathsf{Span}_A(\mathcal{F}_{/X}) : f_!.$$

The underlying $\mathcal{F}$-∞-category of $\underline{\mathsf{NMon}}_{F_A}(\mathcal{X})$ therefore admits the following alternative description: it is given by the composite

$$\mathcal{F}^{\mathrm{op}} \xrightarrow{\mathsf{Span}_A(\mathcal{F}_{/-})} (\mathsf{Cat}_\infty^{\times})^{\mathrm{op}} \xrightarrow{\mathsf{Fun}^{\times}(-,\mathcal{X})} \mathsf{Cat}_\infty,$$

i.e. its functoriality is given via restriction along pushforwards.

Remark 4.1.11. If $\mathcal{X}$ is presentable and $(\mathcal{F}, \mathcal{F}_A) = (\mathbb{F}[T], \mathbb{F}[P])$ for a small ∞-category T and a left-cancellable orbital subcategory $P \subseteq T$ consisting of truncated maps, then the $\mathcal{F}$-∞-category $\underline{\mathsf{NMon}}_{F_A}(\mathcal{X})$ is studied in [CLL24, §9.2] under the name $\underline{\mathsf{Mack}}^P_T(\mathcal{X})$. Corollary 9.9 of said article establishes a universal property for this $\mathcal{F}$-∞-category, and shows that whenever P is a so-called *atomic* orbital subcategory it agrees with the $\mathcal{F}$-∞-category $\underline{\mathsf{CMon}}^P_T(\underline{\mathcal{X}}_T)$ of [CLL23a, §4.8]. In particular, if in addition $P = T$, this further agrees with Nardin's $\underline{\mathsf{CMon}}_T(\underline{\mathcal{X}}_T)$ [Nar16, 4.9].

Definition 4.1.12. Let $\mathcal{X}$ be as in Definition 4.1.8. An *F-normed semiring* in $\mathcal{X}$ is an F_M-normed algebra in $\underline{\mathsf{NMon}}_{F_A}(\mathcal{X})$; we write

$$\mathsf{NRig}_F(\mathcal{X}) := \mathsf{NAlg}_{F_M}\big(\underline{\mathsf{NMon}}_{F_A}(\mathcal{X})\big).$$

Example 4.1.13. Let $F = (\mathbb{F}, \mathbb{F}, \mathbb{F})$. Combining Examples 3.1.6 and 4.1.9, we see that $\mathsf{NRig}_F(\mathcal{X})$ agrees with the ∞-category $\mathcal{R}ig_{\mathbb{E}_\infty}(\mathcal{X})$ of $\mathbb{E}_\infty$-semirings considered by Gepner, Groth, and Nikolaus [GGN15, 7.1].

4.2 The Lawvere theory of normed semirings

Let $F = (\mathcal{F}, \mathcal{F}_M, \mathcal{F}_A)$ be a semiring context. Since F is in particular a bispan triple by Observation 4.1.2, we may form its bispan category $\mathsf{Bispan}_{M,A}(\mathcal{F})$. Our goal in this subsection is to show that the ∞-category $\mathsf{Bispan}_{M,A}(\mathcal{F})$ is the *Lawvere theory for F-normed semirings*: for any ∞-category $\mathcal{X}$ satisfying the conditions from Definition 4.1.8, the ∞-category of F-normed semirings in $\mathcal{X}$ is equivalent to the ∞-category of product-preserving functors $\mathsf{Bispan}_{M,A}(\mathcal{F}) \to \mathcal{X}$. This in particular allows us to think of an F-normed semiring R in $\mathcal{X}$ as a family of objects $R(X)$ for all $X \in \mathcal{F}$ equipped with restrictions $f^*\colon R(Y) \to R(X)$, additive norms $a_\oplus\colon R(X) \to R(Y)$, and multiplicative norms $m_\otimes\colon R(X) \to R(Y)$, which satisfy various compatibility relations exhibited by the respective composition laws in $\mathsf{Bispan}_{M,A}(\mathcal{F})$.

We start with some preliminary statements.

Proposition 4.2.1. *The F_M-normed structure on $\mathsf{Span}_A(\underline{\mathcal{F}})$ induced by the cartesian F_M-normed structure on $\underline{\mathcal{F}}$ is given by*

$$\mathsf{Span}_A(\underline{\mathcal{F}})^\otimes \simeq \mathsf{Bispan}_{M-\mathrm{pb},A-\mathrm{fw}}(\mathsf{Ar}(\mathcal{F})) = \mathsf{Span}_{A-\mathrm{fw}}(\mathsf{Span}_{M-\mathrm{pb}}(\mathsf{Ar}(\mathcal{F}))^{\mathrm{op}})$$

where $\mathsf{Ar}(\mathcal{F})_{M-\mathrm{pb}}$ denotes the wide subcategory of $\mathsf{Ar}(\mathcal{F})$ whose morphisms are pullback squares over $\mathcal{F}_M$, and $\mathsf{Span}_{M-\mathrm{pb}}(\mathsf{Ar}(\mathcal{F}))_{A-\mathrm{fw}}$ denotes the subcategory of morphisms whose image under ev_1 is an equivalence in $\mathsf{Span}_M(\mathcal{F})$ and whose forward part lives over $\mathcal{F}_A$.

Proof. This follows by combining Proposition 3.2.10 with the description of $\underline{\mathcal{F}}_\times$ from Proposition 3.4.3. □

Explicitly this means a morphism in $\mathsf{Span}_A(\underline{\mathcal{F}})^{\otimes}$ is represented by a diagram

$$\begin{array}{ccccccc} X & \longleftarrow & Y & \longrightarrow & X' & \xrightarrow{a} & X'' \\ \downarrow & & \downarrow & \lrcorner & \downarrow & & \downarrow \\ S & \longleftarrow & T & \xrightarrow[m]{} & S' & = & S' \end{array}$$

with m in $\mathcal{F}_M$ and a in $\mathcal{F}_A$; the cocartesian fibration to $\mathsf{Span}_M(\mathcal{F})$ is given by restricting to the bottom row.

Example 4.2.2. For the semiring context $F = (\mathcal{F}, \mathcal{F}_M, \mathcal{F}^{\simeq})$ from Example 4.1.3, we obtain the F_M-normed structure on $\underline{\mathcal{F}}^{\mathrm{op}}$ given by

$$\mathsf{Span}_{M-\mathrm{pb}}(\mathsf{Ar}(\mathcal{F}))^{\mathrm{op}} \simeq (\underline{\mathcal{F}}_{\times})^{\mathrm{op}}.$$

Moreover, the underlying $\mathcal{F}$-∞-category of $\underline{\mathsf{NMon}}_{T_A}(\mathfrak{X})$ is the $\mathcal{F}$-∞-category

$$\underline{\mathfrak{X}}_{\mathcal{F}} := \mathsf{Fun}^{\times}(\underline{\mathcal{F}}^{\mathrm{op}}, \mathfrak{X}) = \mathsf{Fun}^{\times}(-, \mathfrak{X}) \circ \underline{\mathcal{F}}^{\mathrm{op}}$$

of $\mathcal{F}$-objects in $\mathfrak{X}$.

Corollary 4.2.3. *The ∞-category $\mathsf{NRig}_F(\mathfrak{X})$ of F-normed semirings in $\mathfrak{X}$ is naturally equivalent to the full subcategory $\mathcal{R} \subseteq \mathsf{Fun}(\mathsf{Bispan}_{M-\mathrm{pb},A-\mathrm{fw}}(\mathsf{Ar}(\mathcal{F})), \mathfrak{X})$ spanned by functors*

$$\Phi\colon \mathsf{Bispan}_{M-\mathrm{pb},A-\mathrm{fw}}(\mathsf{Ar}(\mathcal{F})) \longrightarrow \mathfrak{X}$$

such that

(1) *For every object $E \to X$ in $\mathsf{Bispan}_{M-\mathrm{pb},A-\mathrm{fw}}(\mathsf{Ar}(\mathcal{F}))$, where E decomposes as a coproduct $\coprod_{i=1}^n E_i$ in $\mathcal{F}$, evaluating Φ at the morphisms*

$$\begin{array}{ccccccc} E & \longleftarrow & E_i & = & E_i & = & E_i \\ \downarrow & & \downarrow & \lrcorner & \downarrow & & \downarrow \\ X & = & X & = & X & = & X \end{array} \qquad (11)$$

gives an equivalence

$$\Phi(E \longrightarrow X) \xrightarrow{\sim} \prod_{i=1}^{n} \Phi(E_i \longrightarrow X).$$

(2) *Φ takes morphisms of the form*

$$\begin{array}{ccccccc} E & = & E & = & E & = & E \\ \downarrow & & \downarrow & \lrcorner & \downarrow & & \downarrow \\ Y & \longleftarrow & X & = & X & = & X \end{array} \qquad (12)$$

in $\mathsf{Bispan}_{M-\mathrm{pb},A-\mathrm{fw}}(\mathsf{Ar}(\mathcal{F}))$ to equivalences in $\mathfrak{X}$.

Moreover, for every $X \in \mathcal{F}$ this equivalence fits into a commutative diagram

$$\begin{array}{ccc} \mathsf{NRig}_F(\mathcal{X}) & \xrightarrow{\simeq} & \mathcal{R} \\ & {\scriptstyle \mathrm{ev}_A} \searrow \quad \swarrow {\scriptstyle \iota_X^*} & \\ & \mathsf{Fun}^\times(\mathsf{Span}_A(\mathcal{F}_{/X}), \mathcal{X}) & \end{array} \tag{13}$$

where ι_X is induced by $(\mathcal{F}_{/X}, (\mathcal{F}_{/X})^{\simeq}, \mathcal{F}_{/X,A}) \hookrightarrow (\mathsf{Ar}(\mathcal{F}), \mathsf{Ar}(\mathcal{F})_{M-\mathrm{pb}}, \mathsf{Ar}(\mathcal{F})_{A-\mathrm{fw}})$.

Proof. In light of Proposition 4.2.1, we only have to show that the description of the full subcategory $\mathcal{R}$ is equivalent to the description given in Proposition 3.3.1.

Since products in $\mathsf{Span}_A(\mathcal{F}_{/X})$ are given by coproducts in $\mathcal{F}$, the first condition amounts to asking for the restriction

$$\Phi_X \colon \mathsf{Span}_A(\mathcal{F}_{/X}) \longrightarrow \mathcal{X}$$

of Φ to preserve products for every $X \in \mathcal{F}$, which is the first condition formulated in Proposition 3.3.1.

We now claim that (12) defines a cartesian edge over $Y \leftarrow X = X$; Observation 3.3.7 will then immediately show that our second condition is indeed equivalent to the second condition of Proposition 3.3.1. For this we observe that restricting in the target to $\mathcal{F}^{\mathrm{op}} = \mathsf{Span}_{\mathrm{eq}}(\mathcal{F})$ recovers the map $\mathsf{Span}_{A-\mathrm{fw}}(\mathsf{Ar}(\mathcal{F})) \to \mathcal{F}^{\mathrm{op}}$ classifying $\mathsf{Span}_A(\underline{\mathcal{F}})$. The subfibration $\mathsf{Ar}(\mathcal{F})^{\mathrm{op}} \to \mathcal{F}^{\mathrm{op}}$ is both cartesian and cocartesian, with cartesian edges given by the squares in question (the *co*cartesian edges of $\mathsf{Ar}(\mathcal{F}) \to \mathcal{F}$). We therefore want to show that this is still cartesian in $\mathsf{Span}_{A-\mathrm{fw}}(\mathsf{Ar}(\mathcal{F}))$. However, this simply means that the adjunction $f^* \colon (\mathcal{F}_{/X})^{\mathrm{op}} \rightleftarrows (\mathcal{F}_{/Y})^{\mathrm{op}} : f_!$ ought to extend to $\mathsf{Span}_A(\mathcal{F}_{/X}) \rightleftarrows \mathsf{Span}_A(\mathcal{F}_{/Y})$, which was observed in Remark 4.1.10 above. ◻

Theorem 4.2.4. *Composition with* $\mathrm{ev}_0 \colon \mathsf{Bispan}_{M-\mathrm{pb},A-\mathrm{fw}}(\mathsf{Ar}(\mathcal{F})) \to \mathsf{Bispan}_{M,A}(\mathcal{F})$ *induces an equivalence*

$$\mathsf{NRig}_F(\mathcal{X}) \xrightarrow{\sim} \mathsf{Fun}^\times(\mathsf{Bispan}_{M,A}(\mathcal{F}), \mathcal{X})$$

fitting into commutative diagrams

$$\begin{array}{ccc} \mathsf{NRig}_F(\mathcal{X}) & \xrightarrow{\simeq} & \mathsf{Fun}^\times(\mathsf{Bispan}_{M,A}(\mathcal{F}), \mathcal{X}) \\ & {\scriptstyle \mathrm{ev}_X} \searrow \quad \swarrow {\scriptstyle p_X^*} & \\ & \mathsf{Fun}^\times(\mathsf{Span}_A(\mathcal{F}_{/X}), \mathcal{X}) & \end{array} \tag{14}$$

where p_X is induced by the forgetful map $(\mathcal{F}_{/X}, (\mathcal{F}_{/X})^{\simeq}, \mathcal{F}_{/X,A}) \to (\mathcal{F}, \mathcal{F}_M, \mathcal{F}_A)$.

Proof. By [CHLL24, 4.2.2], the functor ev_0 on bispans is a localization. Let W be the class of morphisms it takes to equivalences, which we can immediately simplify to those of the form

$$\begin{array}{ccccccc} X & = & X & = & X & = & X \\ \downarrow & & \downarrow \lrcorner & & \downarrow & & \downarrow \\ S & \longleftarrow & T & \longrightarrow & S' & = & S', \end{array}$$

and let $S \subseteq W$ be the morphisms of the form (12). Arguing as in the proof of [CHLL24, 4.3.1], we see that a functor that inverts S must invert all of W. From Corollary 4.2.3 we know that an F-normed semiring inverts the morphisms in S, and it therefore factors through the localization. All that remains for the equivalence $\mathsf{NRig}_F(\mathfrak{X}) \simeq \mathsf{Fun}^{\times}(\mathsf{Bispan}_{M,A}(\mathcal{F}), \mathfrak{X})$ is to show that a functor $\Phi\colon \mathsf{Bispan}_{M,A}(\mathcal{F}) \to \mathfrak{X}$ preserves products if and only if the composite $\Psi := \Phi \circ \mathrm{ev}_0$ satisfies

$$\Psi(E \longrightarrow X) \xrightarrow{\sim} \prod_i \Psi(E_i \longrightarrow X)$$

for $E \simeq \coprod_i E_i$. Since the product in $\mathsf{Bispan}_{M,A}(\mathcal{F})$ is given by the coproduct in $\mathcal{F}$ by Proposition 2.3.5, the condition for Ψ is immediate if Φ preserves products. Conversely, for any coproduct decomposition $E \simeq \coprod E_i$, we can apply the condition for Ψ with $X = E$ to conclude that Φ preserves this product.

Finally, the commutativity of (14) follows at once from the commutativity of (13) and the observation $p_X = \mathrm{ev}_0 \circ \iota_X$. □

Remark 4.2.5. By Theorem 4.2.4, an F-normed semiring in $\mathfrak{X}$ may be identified with a product-preserving functor $R\colon \mathsf{Bispan}_{M,A}(\mathcal{F}) \to \mathfrak{X}$, and thus gives rise to maps $f^*\colon R(Y) \to R(X)$, $a_\oplus\colon R(X) \to R(Y)$ and $m_\otimes\colon R(X) \to R(Y)$ for morphisms $f, a, m\colon X \to Y$ in $\mathcal{F}$ such that $a \in \mathcal{F}_A$ and $m \in \mathcal{F}_M$. Each of these classes of maps are compatible with composition in $\mathcal{F}$. Furthermore, given pullback squares

$$\begin{array}{ccc} X' & \xrightarrow{g} & X \\ {\scriptstyle a'}\downarrow & \lrcorner & \downarrow{\scriptstyle a} \\ Y' & \xrightarrow{f} & Y \end{array} \qquad \text{and} \qquad \begin{array}{ccc} X' & \xrightarrow{g} & X \\ {\scriptstyle m'}\downarrow & \lrcorner & \downarrow{\scriptstyle m} \\ Y' & \xrightarrow{f} & Y \end{array}$$

with $a \in \mathcal{F}_A$ and $m \in \mathcal{F}_M$, the composition relations in $\mathsf{Bispan}_{M,A}(\mathcal{F})$ give rise to relations $f^* a_\oplus \simeq a'_\oplus g^*$ and $f^* m_\otimes \simeq m'_\otimes g^*$ of maps $R(X) \to R(Y')$. Finally, given morphisms $a\colon X \to Y$ in $\mathcal{F}_A$ and $m\colon Y \to Z$ in $\mathcal{F}_M$, we may consider their associated "distributivity diagram" [EH23, 2.4.1]

$$\begin{array}{ccccc} X & \xleftarrow{e} & m^* m_*(X) & \xrightarrow{m'} & m_*(X) \\ & {\scriptstyle a}\searrow & \downarrow{\scriptstyle b'} & \lrcorner & \downarrow{\scriptstyle b = m_*(a)} \\ & & Y & \xrightarrow{m} & Z, \end{array}$$

where e is the counit of the adjunction $m^* \dashv m_*$; we then obtain a distributivity relation $m_\otimes a_\oplus \simeq b_\oplus m'_\otimes e^*$ of maps $R(X) \to R(Z)$.

Example 4.2.6. Specializing Theorem 4.2.4 to $F = (\mathbb{F}, \mathbb{F}, \mathbb{F})$ as in Example 4.1.13, we obtain equivalences $\mathcal{R}ig_{\mathbb{E}_\infty}(\mathcal{X}) \simeq \mathsf{NRig}_F(\mathcal{X}) \simeq \mathsf{Fun}^\times(\mathsf{Bispan}(\mathbb{F}), \mathcal{X})$, recovering the main result of [CHLL24].

Example 4.2.7. Our main interest is the case $F = (\mathbb{F}_G, \mathbb{F}_G, \mathbb{F}_G)$ for a finite group G, which will be discussed extensively in Section 5.

Example 4.2.8. Applying Theorem 4.2.4 to the case for trivial additive norms from Example 4.2.2, we deduce that F-normed monoids in $\mathcal{X}$ admit an interpretation as F-normed algebras:

$$\mathsf{NAlg}_F(\mathsf{Fun}^\times(\underline{\mathcal{F}}^{\mathrm{op}}, \mathcal{X})) \simeq \mathsf{Fun}^\times(\mathsf{Span}_N(\mathcal{F}), \mathcal{X}) = \mathsf{NMon}_F(\mathcal{X}).$$

We may think of this as the normed analogue of the statement that commutative monoids in $\mathcal{X}$ are the commutative algebras with respect to the cartesian symmetric monoidal structure on $\mathcal{X}$.

4.3 Normed rings and Tambara functors

Fix a cocomplete ∞-category $\mathcal{X}$ with finite products such that the cartesian product preserves colimits in each variable. Among the normed semirings in $\mathcal{X}$, we are especially interested in those that behave like *rings*, in the sense that their underlying additive monoid is in fact a group:

Definition 4.3.1. Suppose $F_A = (\mathcal{F}, \mathcal{F}_A)$ is an extensive span pair (and not only a *weakly* extensive one). We then say an F_A-normed monoid $M\colon \mathsf{Span}_A(\mathcal{F}) \to \mathcal{X}$ is *grouplike* if the induced commutative monoid structure on $M(X)$ from Observation 3.1.2 is grouplike in the usual sense for every $X \in \mathcal{F}$. We also refer to grouplike F_A-normed monoids as *F_A-normed groups* and write $\mathsf{NGrp}_{F_A}(\mathcal{X}) \subseteq \mathsf{NMon}_{F_A}(\mathcal{X})$ for the full subcategory of these. Note that under the equivalence (6), the full subcategory $\mathsf{NGrp}_{F_A}(\mathcal{X})$ corresponds to the subcategory

$$\mathsf{NMon}_{F_A}(\mathsf{CGrp}(\mathcal{X})) \subseteq \mathsf{NMon}_{F_A}(\mathsf{CMon}(\mathcal{X})) \simeq \mathsf{NMon}_{F_A}(\mathcal{X}).$$

If $\mathcal{X}$ is presentable, then $\mathsf{NGrp}_{F_A}(\mathcal{X})$ is an accessible localization of $\mathsf{NMon}_{F_A}(\mathcal{X})$, and so is again presentable.

Definition 4.3.2. A *ring context* is a semiring context $F = (\mathcal{F}, \mathcal{F}_M, \mathcal{F}_A)$ such that the span pair $F_A = (\mathcal{F}, \mathcal{F}_A)$ is extensive. An *F-normed ring in $\mathcal{X}$* is an F-normed semiring $R\colon \mathsf{Span}_M(\mathcal{F}) \to \underline{\mathsf{NMon}_{F_A}}(\mathcal{X})^\otimes$ such that for all $X \in \mathcal{F}$ the resulting $F_{/X,A}$-normed monoid $R_X\colon \mathsf{Span}_A(\mathcal{F}_{/X}) \to \mathcal{X}$ is an $F_{/X,A}$-normed group; here $F_{/X,A} = (\mathcal{F}_{/X}, \mathcal{F}_{/X,A})$ denotes the span pair from Example 3.1.8.

Example 4.3.3. The semiring contexts arising in equivariant mathematics, discussed in Example 4.1.5, are always ring contexts.

Warning 4.3.4. In the generality of our setup, the F_M-normed structure on $\underline{\mathsf{NMon}}_{F_A}(\mathcal{X})$ need not descend to grouplike objects: the latter may only form what should be called a F_M-∞-*operad*, and the previous definition could then be more succinctly phrased as saying that an F-normed ring is an F_M-normed algebra in this parametrized ∞-operad.

However, we will show in the next section that such a normed structure *does* exist in the setting of equivariant homotopy theory, which is the main case of interest to us.

Definition 4.3.5. A product-preserving functor $\mathsf{Bispan}_{M,A}(\mathcal{F}) \to \mathcal{X}$ is called an ($\mathcal{X}$-valued) F-*Tambara functor* if its restriction to $\mathsf{Span}_A(\mathcal{F}) \simeq \mathsf{Bispan}_{\mathrm{eq},A}(\mathcal{F})$ is grouplike in the sense of Definition 4.3.1. We write

$$\mathsf{Tamb}_F(\mathcal{X}) \subseteq \mathsf{Fun}^\times(\mathsf{Bispan}_{M,A}(\mathcal{F}), \mathcal{X})$$

for the full subcategory spanned by the Tambara functors.

Theorem 4.3.6. *Let $F = (\mathcal{F}, \mathcal{F}_M, \mathcal{F}_A)$ be a ring context. Then the equivalence $\mathsf{NRig}_F(\mathcal{X}) \simeq \mathsf{Fun}^\times(\mathsf{Bispan}_{M,A}(\mathcal{F}), \mathcal{X})$ constructed in Theorem 4.2.4 restricts to*

$$\mathsf{NRing}_F(\mathcal{X}) \simeq \mathsf{Tamb}_F(\mathcal{X}).$$

Proof. Write $\Phi\colon \mathsf{NRig}_F(\mathcal{X}) \to \mathsf{Fun}^\times(\mathsf{Bispan}_{M,A}(\mathcal{F}), \mathcal{X})$ for the equivalence from Theorem 4.2.4; we have to show that an F-normed semiring $R \in \mathsf{NRig}_F(\mathcal{X})$ is an F-normed ring if and only if $\Phi(R)$ is grouplike.

By commutativity of (14), R is an F-normed ring if and only if $\Phi(R) \circ p_X$ is grouplike for every $X \in \mathcal{F}$; we have to show that this is in turn equivalent to the composite $\phi\colon \mathsf{Span}_A(\mathcal{F}) \to \mathsf{Bispan}_{M,A}(\mathcal{F}) \to \mathcal{X}$ being grouplike. But indeed, if $\hat{\phi}\colon \mathsf{Span}_A(\mathcal{F}) \to \mathsf{CMon}(\mathcal{X})$ is the unique lift of ϕ, its restriction along $\mathsf{Span}_A(\mathcal{F}_{/X}) \to \mathsf{Span}_A(\mathcal{F})$ is a lift of $\Phi(R) \circ p_X$; the claim follows as the functors $\mathsf{Span}_A(\mathcal{F}_{/X}) \to \mathsf{Span}_A(\mathcal{F})$ for varying $X \in \mathcal{F}$ are jointly surjective. □

5 Normed equivariant spectra

In this section, we will prove the main results of our paper: In particular, we will define the G-normed ∞-category of G-spectra, compare it to G-commutative groups, and then finally specialize the results of the previous sections to describe connective normed G-spectra in terms of Tambara functors.

Convention 5.0.1. We will fix the ring context $F = (\mathbb{F}_G, \mathbb{F}_G, \mathbb{F}_G)$ throughout the whole section, write "G-∞-category" instead of "$\mathbb{F}_G$-∞-category", and write "normed" instead of "F-normed." It will be convenient to think of normed G-∞-categories as functors $\mathsf{Span}(\mathbb{F}_G) \to \mathsf{CMon}(\mathsf{Cat}_\infty)$, via Observation 3.1.2. We will furthermore repurpose the notation $\mathcal{C}^\otimes$ to refer to a normed G-∞-category $\mathsf{Span}(\mathbb{F}_G) \to \mathsf{CMon}(\mathsf{Cat}_\infty)$ with underlying G-∞-category $\mathcal{C}\colon \mathbb{F}_G^{\mathrm{op}} \to \mathsf{Cat}_\infty$.

5.1 Presentable G-∞-categories

Unlike in the rest of this paper, we will need a fair bit of parametrized higher category theory [BDG⁺16, MW21] in this section, and we begin by recalling some of the basic terminology. For simplicity, we will restrict to the case of G-∞-categories here, although our references work in much greater generality.

Construction 5.1.1. The ∞-category $\mathsf{Fun}^\times(\mathbb{F}_G^{\mathrm{op}}, \mathsf{Cat}_\infty) \simeq \mathsf{Fun}(\mathbf{O}_G^{\mathrm{op}}, \mathsf{Cat}_\infty)$ of G-∞-categories is cartesian closed. We write $\underline{\mathsf{Fun}}_G$ for the internal hom, and $\mathsf{Fun}_G = \mathrm{ev}_{G/G} \circ \underline{\mathsf{Fun}}_G$ for its underlying ordinary ∞-category.

Using Fun_G, we can view the ∞-category of G-∞-categories as an $(\infty, 2)$-category; all that we will need below is that this enhances the homotopy 1-category to a 2-category. In particular, we obtain a natural notion of *adjunctions* between G-∞-categories. The following recognition principle will be useful:

Lemma 5.1.2 ([MW21, 3.2.9 and 3.2.11])**.** *A functor $F\colon \mathscr{C} \to \mathscr{D}$ of G-∞-categories admits a right adjoint if and only if the following hold:*

(1) For each $X \in \mathbf{O}_G$ (or equivalently for each $X \in \mathbb{F}_G$), the functor $F_X\colon \mathscr{C}(X) \to \mathscr{D}(X)$ admits a right adjoint G_X in the usual sense.

(2) For each $f\colon X \to Y$ in $\mathbf{O}_G$ (or equivalently for f in $\mathbb{F}_G$) the Beck–Chevalley transformation $f^*G_Y \to G_X f^*$ is invertible. □

Definition 5.1.3. A G-∞-category $\mathscr{C}\colon \mathbb{F}_G \to \mathsf{Cat}_\infty$ is called *presentable* if it satisfies all of the following conditions:

(1) It factors through Pr^{L}.

(2) For each $g\colon C \to D$ in $\mathbb{F}_G$ the functor $g^*\colon \mathscr{C}(D) \to \mathscr{C}(C)$ admits a left adjoint $g_!$, and for any pullback square

$$\begin{array}{ccc} A & \xrightarrow{f} & B \\ {\scriptstyle p}\downarrow & \lrcorner & \downarrow{\scriptstyle q} \\ C & \xrightarrow[g]{} & D \end{array}$$

the Beck–Chevalley map $f_!p^* \to q^*g_!$ is invertible.

Corollary 5.1.4 ([MW22, 6.3.1])**.** *A functor $F\colon \mathscr{C} \to \mathscr{D}$ of presentable G-∞-categories is a left adjoint if and only if it* ***preserves G-colimits*** *in the following sense: F is left adjointable, and for every $X \in \mathbf{O}_G$ (or equivalently $\mathbb{F}_G$) the functor $\mathscr{C}(X) \to \mathscr{D}(X)$ preserves ordinary colimits.*

Proof. By the Adjoint Functor Theorem the latter condition is equivalent to each $\mathscr{C}(X) \to \mathscr{D}(X)$ admitting a right adjoint G_X. By passing to total mates, the former condition is then equivalent to the Beck–Chevalley maps $f^*G_Y \to G_X f^*$ being invertible. Thus, the claim follows from Lemma 5.1.2. □

Definition 5.1.5. We denote the ∞-category of presentable G-∞-categories and left adjoint (equivalently: G-cocontinuous) functors by $\mathsf{Pr}^{\mathrm{L}}_{G}$.

Remark 5.1.6. For every $\mathscr{C}, \mathscr{D} \in \mathsf{Pr}^{\mathrm{L}}_{G}$, there is a G-subcategory $\underline{\mathsf{Fun}}^{\mathrm{L}}_{G}(\mathscr{C}, \mathscr{D}) \subseteq \underline{\mathsf{Fun}}_{G}(\mathscr{C}, \mathscr{D})$ of the internal hom, given in degree G/G by the full subcategory of left adjoint functors $\mathscr{C} \to \mathscr{D}$; we refer the reader to [CLL23a, 2.3.22] or [MW21, discussion before 3.3.6] for details. As we will recall in the proof of Theorem 5.4.10 below, this is the internal hom for a parametrized analogue of the Lurie tensor product.

5.2 The G-∞-category of G-spaces

As a warm-up and an ingredient for the construction of the normed G-∞-category of G-spectra, we will recall two equivalent constructions of the G-∞-category of G-*spaces* in this subsection, and show that it admits a unique normed structure interacting suitably with (pointwise) colimits.

We begin with a construction via classical equivariant homotopy theory:

Construction 5.2.1. Let SSet be the 1-category of simplicial sets. Applying Construction A.1.1, we obtain a *Borel G-category* $\mathsf{SSet}^\flat$, given slightly informally as follows: $\mathsf{SSet}^\flat$ sends G/H to the category of simplicial sets with (strict) H-action, with contravariant functoriality via restricting the action.

We now equip each $\mathsf{SSet}^\flat(G/H) = \mathsf{Fun}(BH, \mathsf{SSet})$ with the H-equivariant weak equivalences, i.e. those maps f such that f^K is a weak homotopy equivalence for every $K \leqslant H$. As these are clearly stable under restriction, this defines a lift of $\mathsf{SSet}^\flat$ to a functor from $\mathbf{O}_G^{\mathrm{op}}$ to relative categories. Postcomposing with Dwyer–Kan localization, we therefore obtain a G-∞-category $\underline{\mathfrak{S}}_G$.

We moreover write $\underline{\mathfrak{F}}_G$ for the Borel G-category $\mathbb{F}^\flat$; equivalently, this is the full subcategory of $\underline{\mathfrak{S}}_G$ spanned in degree G/H by the finite H-sets.

Next, let us compare this to a purely ∞-categorical construction.

Construction 5.2.2. We write $\underline{\mathbb{F}}_G$ for the G-∞-category $X \mapsto (\mathbb{F}_G)_{/X}$ and $\underline{\mathsf{Spc}}_G$ for the G-∞-category $\mathscr{P}_\Sigma(\underline{\mathbb{F}}_G) \coloneqq \mathsf{Fun}^\times(\underline{\mathbb{F}}_G^{\mathrm{op}}, \mathsf{Spc})$, with functoriality via left Kan extension (cf. Proposition 3.3.2). By [HHLN23, 8.1] the Yoneda embeddings assemble into a G-functor $\underline{\mathbb{F}}_G \hookrightarrow \underline{\mathsf{Spc}}_G$, exhibiting the target as the pointwise sifted cocompletion.

Remark 5.2.3. Equivalently, $\underline{\mathsf{Spc}}_G$ is obtained from the "co-G-∞-category" $\mathbb{F}_G \to \mathsf{Cat}_\infty, X \mapsto (\mathbb{F}_G)_{/X}$ (functoriality via pushforward) by applying the *contravariant* functor $\mathsf{Fun}^\times(-, \mathsf{Spc})$. As the inclusion $(\mathbf{O}_G)_{/X} \hookrightarrow (\mathbb{F}_G)_{/X}$ is the finite coproduct completion for every $X \in \mathbf{O}_G$, we can also describe this as the functor $\mathbf{O}_G^{\mathrm{op}} \to \mathsf{Cat}_\infty, X \mapsto \mathsf{Fun}((\mathbf{O}_G)_{/X}^{\mathrm{op}}, \mathsf{Spc})$. The latter description serves as the definition of $\underline{\mathsf{Spc}}_G$ in [CLL23b].

Theorem 5.2.4. *There are unique equivalences $\underline{\mathfrak{S}}_G \simeq \underline{\mathsf{Spc}}_G$ and $\underline{\mathfrak{F}}_G \simeq \underline{\mathbb{F}}_G$ of G-∞-categories. Moreover, these equivalences fit into a commutative diagram*

$$\begin{array}{ccc} \underline{\mathfrak{F}}_G & \hookrightarrow & \underline{\mathfrak{S}}_G \\ {\scriptstyle\simeq}\downarrow & & \downarrow{\scriptstyle\simeq} \\ \underline{\mathbb{F}}_G & \underset{\text{Yoneda}}{\hookrightarrow} & \underline{\mathsf{Spc}}_G. \end{array}$$

Proof. By [CLL23b, 5.12] there exists a unique equivalence $\Phi\colon \underline{\mathfrak{S}}_G \xrightarrow{\sim} \underline{\mathsf{Spc}}_G$. By virtue of being an equivalence, this preserves (levelwise) terminal objects and G-colimits.

Let now $K \leqslant H \leqslant G$. Then both the restriction $i^*\colon \mathsf{Fun}(BH, \mathsf{SSet}) \to \mathsf{Fun}(BK, \mathsf{SSet})$ as well as its 1-categorical left adjoint $i_!$ are homotopical; thus, the ∞-categorical left adjoint $i_!\colon \underline{\mathfrak{S}}_G(G/K) \to \underline{\mathfrak{S}}_G(G/H)$ can simply be computed by the 1-categorical left adjoint. In the same way, we see that terminal objects and coproducts in $\underline{\mathfrak{S}}_G$ can be computed in the 1-category SSet. In particular, we have $H/K = i_!i^*(1_K)$ in $\underline{\mathfrak{S}}_G$, whence

$$\Phi(H/K) \simeq i_!i^*(\mathrm{id}_{G/H}) \simeq (G/K \twoheadrightarrow G/H) \in (\mathbb{F}_G)_{/(G/H)}.$$

It follows by direct inspection that Φ maps $\mathbf{O}_H \subseteq \underline{\mathfrak{F}}_G(G/H)$ essentially surjectively into $(\mathbf{O}_G)_{/(G/H)} \subseteq \underline{\mathbb{F}}_G(G/H)$, and closing up under finite coproducts we see that the equivalence Φ restricts to a functor $\phi\colon \underline{\mathbb{F}}_G \to \underline{\mathfrak{F}}_G$ that is essentially surjective, and hence itself an equivalence.

Finally, $\underline{\mathbb{F}}_G$ has no non-trivial automorphisms by [CLL23a, 4.2.17], which completes the proof of the proposition. □

Remark 5.2.5. As recalled in [CLL23a, 2.4.11], $\underline{\mathsf{Spc}}_G$ is the *free presentable G-∞-category on a point* in the following sense: for any $\mathscr{C} \in \mathsf{Pr}^{\mathrm{L}}_G$ evaluation at the terminal object of $\mathsf{Spc}_G(G/G)$ defines an equivalence $\underline{\mathsf{Fun}}^{\mathrm{L}}_G(\underline{\mathsf{Spc}}_G, \mathscr{C}) \xrightarrow{\sim} \mathscr{C}$.

We can also give a pointed version of the above comparison:

Construction 5.2.6. Consider the category SSet_* of pointed simplicial sets. As before, we can associate to this a G-1-category $\mathsf{SSet}^\flat_*$, $G/H \mapsto \mathsf{Fun}(BH, \mathsf{SSet}_*)$, which we then localize at the (underlying) equivariant weak equivalences to obtain a G-∞-category $\underline{\mathfrak{S}}_{G,*}$. As the equivariant weak equivalences are part of a left proper model structure, we get a natural equivalence $\underline{\mathfrak{S}}_{G,*} \simeq (\underline{\mathfrak{S}}_G)_*$ compatible with the forgetful functors.

We further write $\underline{\mathfrak{F}}_{G,*}$ for the full subcategory spanned in degree G/H by the finite pointed H-sets, so that $\underline{\mathfrak{F}}_{G,*} \simeq (\underline{\mathfrak{F}}_G)_*$.

Corollary 5.2.7. *There is a commutative diagram*

$$\begin{array}{ccc} \underline{\mathfrak{F}}_{G,*} & \hookrightarrow & \underline{\mathfrak{S}}_{G,*} \\ {\scriptstyle\simeq}\downarrow & & \downarrow{\scriptstyle\simeq} \\ (\underline{\mathbb{F}}_G)_* & \hookrightarrow & (\underline{\mathsf{Spc}}_G)_*. \end{array}$$

in which the vertical maps are equivalences and the top and bottom vertical arrow exhibit their targets as sifted cocompletion of the respective sources.

Proof. In light of Theorem 5.2.4, the only non-trivial statement is that the horizontal maps define sifted cocompletions. For this it will be enough to consider the bottom arrow, where this is an immediate consequence of [BH21, 4.1] as every $(Y \to X \to Y) \in \left((\mathbb{F}_G)_{/Y}\right)_*$ is disjointly based. □

Next, we turn our attention to normed structures on these G-∞-categories; we restrict to the pointed case here (as this is the only one we will need below), although the unbased case is analogous.

Proposition 5.2.8. *There exists a unique normed structure on $\underline{\mathfrak{F}}_{G,*}$ with unit S^0 such that the symmetric monoidal product on $\underline{\mathfrak{F}}_{G,*}(G/e) = \mathbb{F}_*$ preserves finite coproducts in each variable.*

Proof. By Corollary A.2.4, it will suffice that $\mathbb{F}_*$ (with trivial G-action) has a unique lift to $\mathsf{Fun}(BG, \mathsf{CMon}(\mathsf{Cat}_\infty))$ with unit S^0 and for which the tensor product preserves finite coproducts in each variable. Consider for this the version of the Lurie tensor product on $\mathsf{Cat}^{\amalg}$ representing functors that preserve finite coproducts in each variable. Then $(\mathbb{F}_*, S^0)$ is an idempotent object for this tensor product by e.g. [CLL23a, 4.7.6], whence it is also idempotent in $\mathsf{Fun}(BG, \mathsf{Cat}^{\amalg})$ with the levelwise symmetric monoidal structure. The claim now follows from [Lur17, 4.8.2.9]. □

Combining this with Corollary 5.2.7 and the universal property of sifted cocompletion, we get:

Corollary 5.2.9. *There exists a unique G-normed structure on $\underline{\mathfrak{S}}_{G,*}$ together with a lift of $\underline{\mathfrak{F}}_{G,*} \hookrightarrow \underline{\mathfrak{S}}_{G,*}$ to a normed G-functor such that the following two conditions are satisfied:*

(1) For each $X \in \mathbb{F}_G$, $\underline{\mathfrak{S}}_{G,*}(X)$ is presentably symmetric monoidal.

(2) For each $f: X \to Y$ in $\mathbb{F}_G$, the functor $f_\otimes: \underline{\mathfrak{S}}_{G,*}(X) \to \underline{\mathfrak{S}}_{G,*}(Y)$ preserves sifted colimits.

The analogous statement for $\underline{\mathbb{F}}_{G,*} \hookrightarrow \underline{\mathsf{Spc}}_{G,*}$ holds, and for these normed structures there is a unique normed equivalence $\underline{\mathfrak{S}}^{\otimes}_{G,*} \simeq \underline{\mathsf{Spc}}^{\otimes}_{G,*}$. □

Let us make the normed structure from Corollary 5.2.9 explicit for our favorite model:

Construction 5.2.10. We equip SSet_* with the symmetric monoidal structure coming from the smash product. This then yields a normed structure on the Borel G-category $\mathsf{SSet}^\flat_*$ via Proposition A.2.1. The symmetric monoidal structure on the individual categories $\mathsf{SSet}^\flat_*(G/H)$ is then given by the usual smash product (Observation A.2.5), while Corollary A.3.6 shows that the map

$i_\otimes\colon \mathsf{Fun}(BK, \mathsf{SSet}_*) \to \mathsf{Fun}(BH, \mathsf{SSet}_*)$ for subgroups $K \leqslant H \leqslant G$ is given by the classical *symmetric monoidal norm*, i.e. it sends a K-simplicial set X to $X^{\wedge n}$ where $n = |H/K|$ and H acts on $X^{\wedge n}$ by restricting the natural $\Sigma_n \wr K$-action along a certain homomorphism $H \to \Sigma_n \wr K$; see Construction A.3.4 for details.

Proposition 5.2.11. *The previous construction localizes to a normed structure on $\underline{\mathfrak{S}}_{G,*}$, and this is the normed structure from Corollary 5.2.9.*

Proof. Since $\mathsf{SSet}^\flat_*$ comes with a normed G-functor $\mathbb{F}^\flat_* \to \mathsf{SSet}^\flat_*$ by construction, the only non-trivial statement is that this localizes to a normed structure satisfying the assumptions (1) and (2) of Corollary 5.2.9.

It is clear that the smash product of pointed H-simplicial sets preserves weak equivalences in each variable and is a left Quillen bifunctor (with respect to the model structures where cofibrations are levelwise injections). Thus, it descends to make each $\underline{\mathfrak{S}}_{G,*}(G/H)$ into a presentably symmetric monoidal ∞-category. It remains to show that for every $K \leqslant H$ the symmetric monoidal norm functor $i_\otimes\colon \mathsf{Fun}(BK, \mathsf{SSet}_*) \to \mathsf{Fun}(BH, \mathsf{SSet}_*)$ preserves weak equivalences, and that the resulting functor on localizations preserves sifted colimits.

For the first statement, let f be a K-equivariant weak equivalence; we have to show that for any $j\colon L \hookrightarrow H$ the map $(j^*i_\otimes f)^L$ is a weak equivalence. Rewriting the cospan $G/H \to G/K \leftarrow G/L$ as a span, we see that this splits as a smash product of maps $(i'_\otimes j'^* f)^L$, i.e. after renaming we are reduced to showing that $(i_\otimes f)^H$ is a weak equivalence. But this map agrees with f^K by direct inspection.

For the second statement, we claim that the functor of 1-categories $X \mapsto X^{\wedge n}$ preserves filtered colimits and geometric realization up to *isomorphism*: the first statement is clear, while the second one follows from the fact that geometric realization is given by taking the diagonal of the associated bisimplicial set. As both of these operations are homotopical by [Len20, 1.1.2 and 1.2.57], it follows that $i_\otimes\colon \underline{\mathfrak{S}}_{G,*}(G/K) \to \underline{\mathfrak{S}}_{G,*}(G/H)$ commutes with filtered colimits and Δ^{op}-shaped colimits, hence with all sifted colimits as claimed. □

5.3 Norms on G-Mackey functors

As a next step, we will show that also the G-∞-category of normed G-monoids/G-Mackey functors from Example 3.1.4 admits a unique normed structure. As a special case of Definition 4.1.8, we obtain one such normed structure

$$\underline{\mathsf{NMon}}_G \coloneqq \underline{\mathsf{NMon}}_G(\mathsf{Spc}) = \mathsf{Fun}^\times(\mathsf{Span}(\underline{\mathbb{F}}_G), \mathsf{Spc}).$$

We begin by relating it to the unstable world:

Proposition 5.3.1. *There exists a unique G-left adjoint $\mathbb{P}\colon \underline{\mathfrak{S}}_{G,*} \to \underline{\mathsf{NMon}}_G$ sending S^0 to $\mathsf{Map}(1, -)$. Moreover, this functor upgrades (canonically) to a normed G-functor.*

Proof. For the first statement, we may equivalently consider $\underline{\mathsf{Spc}}_{G,*} = \underline{\mathsf{Spc}}_G \otimes \mathsf{Spc}_*$ in lieu of $\underline{\mathfrak{S}}_{G,*}$. In this case, the existence and uniqueness of the G-left adjoint $\mathbb{P}$

follows via [CLL24, 7.39] from the universal property of $\underline{\mathsf{Spc}}_G$ (Remark 5.2.5) and the fact that the non-parametrized presentable ∞-category Spc_* is the mode for pointed presentable ∞-categories [Lur17, 4.8.2.11].

To complete the proof, we will now construct a G-left adjoint normed G-functor $\underline{\mathfrak{S}}^{\otimes}_{G,*} \to \underline{\mathsf{NMon}}^{\otimes}_G$. For this, note first that by [CLL23a, 4.7.6] the inclusion $\mathbb{F} \hookrightarrow \mathsf{Span}(\mathbb{F})$ extends (uniquely) to a coproduct-preserving functor $j\colon \mathbb{F}_* \to \mathsf{Span}(\mathbb{F})$, and as both sides are idempotents in $\mathsf{Cat}^{\amalg}$ (see [Har20, 5.3] for the target) this uniquely upgrades to a symmetric monoidal functor. Passing to Borel G-∞-categories we obtain a normed G-functor

$$\underline{\mathfrak{F}}_{G,*} = \underline{\mathbb{F}}_G^{\flat} \longrightarrow \mathsf{Span}(\mathbb{F})^{\flat} \simeq \mathsf{Span}(\underline{\mathbb{F}}_G)$$

sending S^0 to $\mathbf{1}$; here the final equivalence uses that $\mathsf{Span}(\underline{\mathbb{F}}_G) \simeq \mathsf{Span} \circ \underline{\mathfrak{F}}_{G,*}$ is a Borel G-∞-category as postcomposing with the limit preserving functor Span preserves right Kan extensions. Passing to sifted cocompletions and using that

$$\mathsf{Fun}^{\times}(\mathsf{Span}(\underline{\mathbb{F}}_G), \mathsf{Spc}) \simeq \mathsf{Fun}^{\times}(\mathsf{Span}(\underline{\mathbb{F}}_G)^{\mathrm{op}}, \mathsf{Spc}) = \mathcal{P}_{\Sigma}(\mathsf{Span}(\mathbb{F}_G)),$$

we then get a normed G-functor $\underline{\mathfrak{S}}^{\otimes}_{G,*} \to \underline{\mathsf{NMon}}^{\otimes}_G$, whose underlying G-functor agrees up to equivalence with $\mathcal{P}_{\Sigma}(j^{\flat})\colon \mathcal{P}_{\Sigma}(\mathbb{F}_*^{\flat}) \to \mathcal{P}_{\Sigma}(\mathsf{Span}(\mathbb{F})^{\flat})$, i.e. it is the restriction of the left Kan extension along $(j^{\flat})^{\mathrm{op}}$ to product-preserving functors.

To see that this is a G-left adjoint, we first note that each $\mathcal{P}_{\Sigma}(j^{\flat})(G/H)$ admits a right adjoint (given by restriction); it therefore only remains to check the Beck–Chevalley condition of Corollary 5.1.4. For this we observe that for any inclusion $i\colon K \hookrightarrow H$ of subgroups of G, the functors $i^*\colon \mathsf{Fun}(BH, \mathbb{F}_*) \to \mathsf{Fun}(BK, \mathbb{F}_*)$ and $\mathsf{Fun}(BH, \mathsf{Span}(\mathbb{F})) \to \mathsf{Fun}(BK, \mathsf{Span}(\mathbb{F}))$ admit left adjoints $i_!$, given non-equivariantly by an $|H/K|$-fold coproduct. Thus, we may check the Beck–Chevalley condition before passing to sifted cocompletions, i.e. we want to show that $i_! \circ \mathsf{Fun}(BK, j) \to \mathsf{Fun}(BH, j) \circ i_!$ is an equivalence of functors $\mathsf{Fun}(BK, \mathbb{F}_*) \to \mathsf{Fun}(BH, \mathsf{Span}(\mathbb{F}))$. But this may be checked after forgetting to $\mathsf{Span}(\mathbb{F})$, where this follows from the fact that j preserves finite coproducts by construction. □

Restricting, we in particular get a normed structure on the G-functor $\underline{\mathfrak{F}}_{G,*} \to \underline{\mathsf{NMon}}_G$. In fact, this once again uniquely characterizes the normed structure if we in addition impose compatibility with colimits:

Proposition 5.3.2. *There exists a unique pair of a normed structure on $\underline{\mathsf{NMon}}_G$ and a normed structure on the G-functor $\underline{\mathfrak{F}}_{G,*} \to \underline{\mathsf{NMon}}_G$ such that the following conditions are satisfied:*

(1) For each $H \leqslant G$, the symmetric monoidal ∞-category $\underline{\mathsf{NMon}}_G(G/H)$ is presentably symmetric monoidal.

(2) For each $K \leqslant H \leqslant G$ the norm $\underline{\mathsf{NMon}}_G(G/H) \to \underline{\mathsf{NMon}}_G(G/K)$ preserves sifted colimits.

Proof. We will first prove this statement with $\underline{\mathfrak{F}}_{G,*}$ replaced by $\mathsf{Span}(\underline{\mathfrak{F}}_G)$. As $\underline{\mathsf{NMon}}_G$ is defined as the sifted cocompletion of the latter, the same argument as in Corollary 5.2.9 reduces this to showing that $(\mathsf{Span}(\mathbb{F}), 1)$ is idempotent in $\mathsf{Cat}^{\amalg}$, which was already recalled above.

To complete the proof, we now observe that the data in question is equivalent to a normed structure on $\underline{\mathsf{NMon}}_G$ (satisfying the above two axioms) that preserves the full subcategory $\mathsf{Span}(\underline{\mathfrak{F}}_G)$, together with a lift of $\underline{\mathfrak{F}}_{G,*} \to \mathsf{Span}(\underline{\mathfrak{F}}_G)$ to a normed G-functor. The former is no data by the above, while Corollary A.2.2 together with the idempotency of $\mathbb{F}_*$ and $\mathsf{Span}(\mathbb{F})$ shows that also the latter is unique. □

5.4 G-spectra and their symmetric monoidal structure

Let us begin by giving two equivalent descriptions of the G-∞-category of G-spectra:

Construction 5.4.1. We define the G-∞-category $\underline{\mathsf{Sp}}_G$ of G-spectra as the pointwise stabilization of $\underline{\mathsf{NMon}}_G$, i.e. it is the G-∞-category

$$X \mapsto \mathsf{Fun}^{\times}(\mathsf{Span}((\mathbb{F}_G)_{/X}), \mathsf{Sp})$$

with functoriality via restriction along pushforwards. This comes with a natural *stabilization map* $\ell\colon \underline{\mathsf{NMon}}_G \to \underline{\mathsf{Sp}}_G$, induced by the usual stabilization/delooping map $\mathsf{CMon}(\mathsf{Spc}) \to \mathsf{Sp}$. We write $\mathbb{S}_G$ for the image of $\mathsf{Map}(1, -) \in \underline{\mathsf{NMon}}_G(G/G)$ under ℓ.

Construction 5.4.2. Write Sp^{Σ} for the 1-category of symmetric spectra in simplicial sets. For each finite group H, the category Sp^{Σ} carries an *equivariant flat model structure* [Haus17, 4.7] whose weak equivalences are the so-called H-equivariant weak equivalences and whose cofibrations are the so-called *flat cofibrations*; the latter are independent of the group H. We write $\mathsf{Sp}^{\Sigma}_{\text{flat}}$ for the full subcategory of flat spectra (i.e. those X for which $\emptyset \to X$ is a flat cofibration).

We now consider the Borel G-category $(\mathsf{Sp}^{\Sigma}_{\text{flat}})^{\flat}$, and we equip each category $(\mathsf{Sp}^{\Sigma}_{\text{flat}})^{\flat}(G/H) = \mathsf{Fun}(BH, \mathsf{Sp}^{\Sigma}_{\text{flat}})$ with the H-equivariant weak equivalences. By [Haus17, §5.2] these are preserved under restriction, so we can Dwyer–Kan localize this to obtain a G-∞-category $\underline{\mathfrak{Sp}}_G$.

Remark 5.4.3. The inclusion $(\mathsf{Sp}^{\Sigma}_{\text{flat}})^{\flat} \hookrightarrow (\mathsf{Sp}^{\Sigma})^{\flat}$ induces an equivalence of Dwyer–Kan localizations (being pointwise the inclusion of the cofibrant objects of a model category), so we could equivalently have worked without restricting to flat spectra. However, flatness will come in handy below to define the symmetric monoidal and normed structures on $\underline{\mathfrak{Sp}}_G$.

Theorem 5.4.4. *There is a unique equivalence $\underline{\mathfrak{Sp}}_G \simeq \underline{\mathsf{Sp}}_G$ sending $\mathbb{S}_G$ to $\mathbb{S}_G$.*

Proof. Combine [CLL23b, 9.13] with [CLL24, 9.9]. □

Our goal is to make both sides into normed ∞-categories and then upgrade the above equivalence to a normed equivalence. As a stepping stone for this, we will first prove a comparison that does not take norms into account. We therefore introduce:

Definition 5.4.5. A (naïve) *symmetric monoidal G-∞-category* is a functor $\mathbb{F}_G^{\mathrm{op}} \to \mathsf{CMon}(\mathsf{Cat}_\infty)$.

Equivalently, we can view a symmetric monoidal G-∞-category as a commutative monoid in the (ordinary) ∞-category of G-∞-categories with respect to the cartesian product. Restricting along $\mathbb{F}_G^{\mathrm{op}} \hookrightarrow \mathsf{Span}(\mathbb{F}_G)$, every normed G-∞-category has an underlying symmetric monoidal G-∞-category.

We will be particularly interested in the case where the underlying G-∞-category $\mathscr{C}$ is presentable and the tensor product $- \otimes -\colon \mathscr{C} \times \mathscr{C} \to \mathscr{C}$ preserves G-colimits in each variable, i.e. for each G/H the symmetric monoidal structure on $\mathscr{C}(G/H)$ is closed, and for all $i\colon H \hookrightarrow K$ the *projection map*

$$i_!(X \otimes i^*Y) \longrightarrow i_!X \otimes Y$$

(the Beck–Chevalley map associated to $i^*X \otimes i^*Y \simeq i^*(X \otimes Y)$) is invertible. We call a symmetric monoidal G-∞-category *G-presentably symmetric monoidal* in this case. Similarly we say that a normed G-∞-category is *G-presentably normed* if the underlying symmetric monoidal G-∞-category is G-presentably symmetric monoidal.

Example 5.4.6. We have already seen that the normed structure on $\underline{\mathfrak{S}}_{G,*}$ coming from the smash product is presentably symmetric monoidal in each degree. As all functors in sight are homotopical, the projection formula can be checked on the pointset level, where it is a trivial computation.[1]

Example 5.4.7. The usual smash product of (H-)symmetric spectra is homotopical when restricted to flat spectra [Haus17, 6.1], making $\underline{\mathfrak{Sp}}_G$ into a symmetric monoidal G-∞-category. This is again G-presentably symmetric monoidal: the statement for the levelwise tensor product is again clear, while for the projection map we observe that the corresponding non-derived map is again an isomorphism by direct inspection, and that all functors in sight are homotopical on flat spectra.

Example 5.4.8. Also the normed structure on $\underline{\mathsf{NMon}}_G$ is G-presentably symmetric monoidal. For this note first that Proposition 3.3.8 shows that each $\underline{\mathsf{NMon}}_G(X)$ is presentably symmetric monoidal. For the projection formula $i_!(X \otimes i^*Y) \simeq i_!X \otimes Y$ we observe that both sides preserve colimits in X and Y, so we may assume that X and Y are both in the image of the free functor $\mathbb{P}\colon \underline{\mathfrak{S}}_{G,*} \to \underline{\mathsf{NMon}}_G$. In this case, the claim follows by Proposition 5.3.1 together with Example 5.4.6.

[1] This isomorphism of pointed G-(simplicial) sets is sometimes referred to as the *shearing isomorphism*.

Example 5.4.9. As Sp is idempotent, $\underline{\mathsf{Sp}}_G = \mathsf{Sp} \otimes \underline{\mathsf{NMon}}_G$ inherits a symmetric monoidal structure from $\underline{\mathsf{NMon}}_G$ such that each $\underline{\mathsf{Sp}}_G(X)$ is presentably symmetric monoidal, see [GGN15, 5.1]. This is again G-presentably symmetric monoidal: by the universal property of stabilization, the projection formula can be checked after restricting along $\underline{\mathsf{NMon}}_G \to \underline{\mathsf{Sp}}_G$, where this was verified in the previous example.

In fact, the G-presentably symmetric monoidal structures considered in the above examples are unique:

Theorem 5.4.10.

(1) The G-∞-categories $\underline{\mathsf{Spc}}_{G,*}$ and $\underline{\mathfrak{S}}_{G,*}$ admit unique G-presentably symmetric monoidal structures with unit S^0.

(2) The G-∞-category $\underline{\mathsf{NMon}}_G$ admits a unique G-presentably symmetric monoidal structure with unit $\mathsf{Map}(1,-)$.

(3) The G-∞-categories $\underline{\mathsf{Sp}}_G$ and $\underline{\mathfrak{Sp}}_G$ admit unique G-presentably symmetric monoidal structures with unit $\mathbb{S}_G$.

Moreover, the G-functors $\underline{\mathfrak{S}}_{G,*} \to \underline{\mathsf{NMon}}_G \to \underline{\mathsf{Sp}}_G$ considered above enhance uniquely to maps of symmetric monoidal G-∞-categories, as do the equivalences $\underline{\mathsf{Spc}}_{G,*} \simeq \underline{\mathfrak{S}}_{G,*}$ and $\underline{\mathsf{Sp}}_G \simeq \underline{\mathfrak{Sp}}_G$.

Proof. By [MW22, §8.2], the ∞-category of presentable G-∞-categories comes with a *parametrized Lurie tensor product*, corepresenting bifunctors that preserve G-colimits in each variable. The unit is the G-∞-category $\underline{\mathsf{Spc}}_G$, and the tensor product can be computed by the formula

$$\mathscr{C} \otimes \mathscr{D} = \underline{\mathsf{Fun}}^{\mathrm{R}}_G(\mathscr{C}^{\mathrm{op}}, \mathscr{D}) \simeq \underline{\mathsf{Fun}}^{\mathrm{L}}_G(\mathscr{C}, \mathscr{D}^{\mathrm{op}})^{\mathrm{op}}$$

with functoriality in $\mathscr{C}$ given via precomposition, see [MW22, 8.2.11].

It now suffices to show that $(\underline{\mathsf{Spc}}_{G,*}, S^0)$, $(\underline{\mathsf{NMon}}_G, \mathsf{Map}(1,-))$, and $(\underline{\mathfrak{Sp}}_G, \mathbb{S}_G)$ are all idempotent with respect to this tensor product. By the above explicit formula for the tensor product, the statement for $\underline{\mathfrak{Sp}}_G$ is an instance of [CLL23b, 9.13(2)], while the statement for $\underline{\mathsf{NMon}}_G$ follows by combining [CLL23a, 4.8.11] with [CLL24, 9.9].

Finally, for $\underline{\mathsf{Spc}}_{G,*} = \underline{\mathsf{Spc}}_G \otimes \mathsf{Spc}_*$, we recall that $\underline{\mathsf{Spc}}_G \otimes -\colon \mathsf{Pr}^{\mathrm{L}} \to \mathsf{Pr}^{\mathrm{L}}_G$ admits a strong symmetric monoidal structure [MW22, end of 8.3.8]. In particular, it sends the idempotent Spc_* to an idempotent, finishing the proof. □

5.5 Normed structures on G-spectra

In this subsection we will finally construct the G-normed structure on $\underline{\mathsf{Sp}}_G$; in particular, we will show:

Theorem 5.5.1. *There exists a unique pair of a normed structure on $\underline{\mathsf{Sp}}_G$ together with a lift of $\ell\colon \underline{\mathsf{NMon}}_G \to \underline{\mathsf{Sp}}_G$ to a normed G-functor $\ell^{\otimes}\colon \underline{\mathsf{NMon}}_G^{\otimes} \to \underline{\mathsf{Sp}}_G^{\otimes}$ that satisfies the following two properties:*

(1) For each $X \in \mathbb{F}_G$, $\underline{\mathsf{Sp}}_G^{\otimes}(X)$ is presentably symmetric monoidal.

(2) For each $f\colon X \to Y$ in $\mathbb{F}_G$, the norm functor $f_{\otimes}\colon \underline{\mathsf{Sp}}_G^{\otimes}(X) \to \underline{\mathsf{Sp}}_G^{\otimes}(Y)$ preserves sifted colimits.

This will require some further preparations.

Lemma 5.5.2. *Let $\mathcal{J}$ be a small ∞-category with finite coproducts equipped with a symmetric monoidal structure that preserves coproducts in each variable. Then the Day convolution on $\mathsf{Fun}(\mathcal{J}^{\mathrm{op}}, \mathsf{Spc})$ restricts to a symmetric monoidal structure on $\mathcal{P}_{\Sigma}(\mathcal{J}) = \mathsf{Fun}^{\times}(\mathcal{J}^{\mathrm{op}}, \mathsf{Spc})$. Moreover, this is a presentably symmetric monoidal structure, and the tensor product of compact objects is compact again.*

Proof. The fact that this restricts is the content of Proposition 3.3.8, where it is also shown that this is equivalently the localization of the Day convolution structure, whence in particular presentably symmetric monoidal.

For the second statement, we now claim that any compact object in $\mathcal{P}_{\Sigma}(\mathcal{J})$ is a retract of a finite colimit of representables. To prove the claim, consider any $X \in \mathcal{P}_{\Sigma}(\mathcal{J})$, and write it as a colimit $\mathrm{colim}_{i\in I}\, x_i$ in $\mathcal{P}(\mathcal{J}) = \mathsf{Fun}(\mathcal{J}^{\mathrm{op}}, \mathsf{Spc})$ of representables. Applying the localization functor $\mathcal{P}(\mathcal{J}) \to \mathcal{P}_{\Sigma}(\mathcal{J})$ we then also get such a colimit decomposition in $\mathcal{P}_{\Sigma}(\mathcal{J})$. Restricting along a cofinal functor, we may assume that I is a poset [Lur09, 4.2.3.15], and filtering it by its finite subsets, we can express X as a filtered colimit in $\mathcal{P}_{\Sigma}(\mathcal{J})$ of finite colimits of representables, i.e. we have an equivalence

$$\phi\colon X \xrightarrow{\simeq} \mathrm{colim}_{J\subseteq I \text{ finite}}\, \mathrm{colim}_{j\in J}\, x_j.$$

By compactness of X, ϕ has to factor through a map $\psi\colon X \to \mathrm{colim}_{j\in J}\, x_j$ for some finite $J \subseteq I$. The composite $\mathrm{colim}_{j\in J}\, x_j \to \mathrm{colim}_{J\subseteq I \text{ finite}}\, \mathrm{colim}_{j\in J}\, x_j \simeq X$ is then a retraction of ψ, finishing the proof of the claim.

With this, we can now easily prove the second statement: if X and Y are compact, then the above shows that $X \otimes Y$ is again a retract of a finite colimit of representables (using that $\otimes$ preserves colimits in each variable). As representables are compact in $\mathcal{P}$, and hence also in $\mathcal{P}_{\Sigma}$ (using that the latter is closed under filtered colimits), this immediately implies that $X \otimes Y$ is compact, as desired. □

Lemma 5.5.3. *Let $\mathcal{D}$ be presentably symmetric monoidal and pointed. Then the stabilization map $\Sigma^{\infty}\colon \mathcal{D} \to \mathsf{Sp}(\mathcal{D})$ lifts uniquely to a map in $\mathsf{CAlg}(\mathsf{Pr}^{\mathrm{L}})$, and this lift is symmetric monoidal inversion of $\Sigma\mathbb{1}$.*

Proof. The existence and uniqueness of the symmetric monoidal structure follows from idempotency of $(\mathsf{Sp}, \mathbb{S})$ in Pr^{L}, see [GGN15, 5.1]. It therefore only remains to prove that this map is symmetric monoidal inversion.

As the symmetric monoidal product $\otimes$ preserves colimits in each variable, $\Sigma\mathbb{1} \otimes -$ is equivalent to the suspension functor Σ. Expressing $\Sigma^\infty\colon \mathscr{D} \to \mathsf{Sp}(\mathscr{D})$ as the sequential colimit in Pr^{L} along Σ, the claim is therefore an instance of [GM23, C.6] once we show that $\Sigma\mathbb{1}$ is a *symmetric object*, in the sense that for some $n \geq 2$ the automorphism of $(\Sigma\mathbb{1})^{\otimes n}$ induced by the permutation $\sigma :=$ $(1\ 2\ \ldots\ n) \in \Sigma_n$ is trivial. This is in fact true for any odd n as in this case σ has sign $+1$, so that the induced automorphism of S^n also has degree 1. □

Proposition 5.5.4. *For any $X \in \mathbb{F}_G$, the functor $\ell\colon \underline{\mathsf{NMon}}_G(X) \to \underline{\mathsf{Sp}}_G(X)$ is symmetric monoidal inversion of the object $\Sigma\mathbb{1}$ in both $\mathsf{CAlg}(\mathsf{Pr}^{\mathrm{L}})$ and $\mathsf{CAlg}(\mathsf{Cat}^{\mathrm{sifted}})$.*

Proof. Observe first that $\mathbb{1} = \mathsf{Map}(1, -)$ is compact, whence so is $\Sigma\mathbb{1}$. Moreover, we have seen in the proof of Lemma 5.5.3 that $\Sigma\mathbb{1}$ is a symmetric object, while Lemma 5.5.2 shows that the the symmetric monoidal product preserves compact objects and colimits in each variable. Thus, [BH21, 4.1] shows that the universal map in $\mathsf{CAlg}(\mathsf{Pr}^{\mathrm{L}})$ inverting $\Sigma\mathbb{1}$ agrees with the universal map in $\mathsf{CAlg}(\mathsf{Cat}^{\mathrm{sifted}})$. The claim therefore follows from the previous lemma. □

Lemma 5.5.5. *Let $f\colon X \to Y$ be any map in $\mathbb{F}_G$. Then the symmetric monoidal functor $\ell\colon \underline{\mathsf{NMon}}_G(Y) \to \underline{\mathsf{Sp}}_G(Y)$ sends $f_\otimes(\Sigma\mathbb{1})$ to an invertible object.*

Proof. Consider first the special case that f is the projection $G/H \to G/K$ for some $H \leqslant K$. By Theorem 5.4.10, it will be enough to show that the composite

$$\mathfrak{L}\colon \underline{\mathsf{NMon}}_G \xrightarrow{\ell} \underline{\mathsf{Sp}}_G \xrightarrow{\sim} \underline{\mathfrak{Sp}}_G$$

sends $f_\otimes \Sigma\mathsf{Map}(1, -)$ to an invertible object (with respect to the derived smash product of K-equivariant symmetric spectra). For this we compute

$$\mathfrak{L}(f_\otimes \Sigma\mathsf{Map}(1, -)) = \mathfrak{L} f_\otimes \Sigma\mathbb{P}(S^0) \simeq (\mathfrak{L}\mathbb{P})(f_\otimes S^1) \simeq (\mathfrak{L}\mathbb{P})(S^{K/H})$$

where $\mathbb{P}\colon \underline{\mathfrak{S}}_{G,*} \to \underline{\mathsf{NMon}}_G$ is the normed G-left adjoint from Proposition 5.3.1, and the last equation uses the explicit description of the normed structure on $\underline{\mathfrak{S}}_{G,*}$. Now $\mathfrak{L} \circ \mathbb{P}\colon \underline{\mathfrak{S}}_{G,*} \to \underline{\mathfrak{Sp}}_G$ is a G-left adjoint sending S^0 to $\mathbb{S}_G$, so it is necessarily the suspension spectrum functor. But the representation sphere $\Sigma^\infty S^{K/H}$ is invertible with respect to the smash product of K-spectra by [Haus17, 4.9(i)], finishing the proof of the special case.

In the case of a general map $f\colon X \to Y$ in $\mathbb{F}_G$, we first note that an object is invertible in $\underline{\mathsf{Sp}}_G(Y)$ if and only if it is so after restricting to each orbit. By the double coset formula, we may therefore assume that $Y = G/H$. Decomposing X into its orbits then provides a factorization of $X \to G/H$ as

$$X = \coprod_{i=1}^r X_i \xrightarrow{\amalg f_i} \coprod_{i=1}^r G/H \xrightarrow{\nabla} G/H,$$

whence $\ell(f_\otimes \Sigma\mathsf{Map}(1, -)) \simeq \ell\big(\bigotimes_{i=1}^r f_{i\otimes} \Sigma(\mathsf{Map}(1, -))\big) \simeq \bigotimes_{i=1}^r \ell f_{i\otimes}(\Sigma\mathsf{Map}(1, -))$. As invertible elements are closed under tensor product, this completes the proof of the lemma. □

Proof of Theorem 5.5.1. By Theorem 5.4.10, ℓ lifts uniquely to a natural transformation of functors into the ∞-category of presentably symmetric monoidal ∞-categories and sifted-colimit-preserving functors, and by Proposition 5.5.4 this map is pointwise given by symmetric monoidal inversion of $\Sigma\mathbb{1}$. This then uniquely extends to the desired map of normed G-∞-categories (viewed as functors $\mathsf{Span}(\mathbb{F}_G) \to \mathsf{CMon}(\mathsf{Cat}_\infty)$ as per our standing convention) by the universal property of symmetric monoidal inversion combined with the previous lemma. □

Let us now give alternative interpretations of this normed G-∞-category:

Proposition 5.5.6 (cf. [BH21, 9.11 and 9.13])**.** *For every $H \leqslant G$, the symmetric monoidal functor $(\ell \circ \mathbb{P})(G/H)\colon \underline{\mathsf{Spc}}^{\otimes}_{G,*}(G/H) \to \underline{\mathsf{Sp}}^{\otimes}_G(G/H)$ is given by universally inverting the objects of the form $f_\otimes\Sigma\mathbb{1}$ in $\mathsf{CAlg}(\mathsf{Pr}^{\mathrm{L}})$, or equivalently in $\mathsf{CAlg}(\mathsf{Cat}^{\mathrm{sifted}})$.*

Note that Nardin and Shah use this as the *definition* of the normed structure on $\underline{\mathsf{Sp}}_G$ [NS22, 2.4.2], following [BH21, §9.2]. Thus, this result in particular shows that our approach agrees with their construction.

Proof. First note that this holds for $\Sigma^\infty\colon \underline{\mathfrak{S}}_{G,*}(G/H) \to \underline{\mathfrak{Sp}}_G(G/H)$ by [GM23, C.7] together with [Haus17, 7.5].[2] Thus, it will suffice to lift the commutative triangle

$$\begin{array}{ccc} & \underline{\mathfrak{S}}_{G,*} & \\ {}^{\Sigma^\infty}\swarrow & & \searrow^{\ell\circ\mathbb{P}} \\ \underline{\mathfrak{Sp}}_G & \xrightarrow[\simeq]{} & \underline{\mathsf{Sp}}_G \end{array} \tag{15}$$

observed in the proof of Theorem 5.5.1 to a commutative diagram of symmetric monoidal G-∞-categories with respect to the symmetric monoidal structures inherited from the normed structures considered above. This is however clear from Theorem 5.4.10 (using that all of these structures are indeed G-presentably symmetric monoidal by the above). □

Finally, we can also describe the normed structure in terms of models:

Proposition 5.5.7. *The normed structure on $(\mathsf{Sp}^{\Sigma}_{\mathrm{flat}})^\flat$ given by the smash product localizes to a G-presentably normed structure on $\underline{\mathfrak{Sp}}_G$ such that the norm $f_\otimes\colon \underline{\mathfrak{Sp}}^{\otimes}(X) \to \underline{\mathfrak{Sp}}^{\otimes}(Y)$ preserves sifted colimits for every $f\colon X \to Y$ in $\mathbb{F}_G$.*

Proof. In view of Example 5.4.7 it only remains to show that the symmetric monoidal norms $N_K^H\colon \mathsf{Fun}(BK, \mathsf{Sp}^{\Sigma}_{\mathrm{flat}}) \to \mathsf{Fun}(BH, \mathsf{Sp}^{\Sigma}_{\mathrm{flat}})$ (known as the *Hill–Hopkins–Ravenel norms*) are homotopical and that the resulting functors on localizations preserve sifted colimits.

[2] Hausmann a priori just provides a Quillen equivalence without referring to the symmetric monoidal structures on both sides, but the left Quillen functor from symmetric to orthogonal spectra is strong symmetric monoidal with respect to Day convolution, so this automatically gives an equivalence of symmetric monoidal ∞-categories.

The first statement is [Haus17, 6.8]. For the second statement we first observe that both filtered colimits and geometric realization in Sp^Σ are homotopical: namely, both are left Quillen (with respect to the projective model structures on the respective source functor categories) and moreover preserve levelwise weak equivalences (maps $f\colon X \to Y$ such that each $f(A)$ is a $(G \times \Sigma_A)$-weak equivalences) as observed in the proof of Proposition 5.2.11. We moreover claim that both of these constructions preserve flat spectra. To see this, we recall that a symmetric spectrum X is flat if and only if for each finite set A a certain natural *latching map* $L_A(X) \to X(A)$ is levelwise injective, see [Haus17, 2.18]; all that we will need to know is that L_A is defined as a certain colimit, and in particular commutes with geometric realization and all colimits. The two claims now immediately follow as injections of simplicial sets are preserved by filtered colimits and geometric realization.

With this established, it will be enough to show that N_H^G commutes with geometric realization and filtered colimits on the point-set level, up to *isomorphism*. In particular, we can forget about all the actions and simply consider the endofunctor $X \mapsto X^{\wedge n}$ of $\mathsf{Sp}^\Sigma \supseteq \mathsf{Sp}^\Sigma_{\text{flat}}$. The statement about filtered colimits is then clear as the smash product preserves colimits in each variable. Similarly, the statement about geometric realizations reduces to showing that for any $X_\bullet\colon \Delta^{\text{op}} \to \mathsf{Sp}^\Sigma_{\text{flat}}$ and $n \geq 1$ the map

$$\int^{[k]\in\Delta^{\text{op}}} X_k \wedge \Delta^k_+ \longrightarrow \int^{[k_1],\dots,[k_n]\in(\Delta^{\text{op}})^n} X_{k_1} \wedge \cdots \wedge X_{k_n} \wedge \Delta^{k_1}_+ \wedge \cdots \wedge \Delta^{k_n}_+$$

induced by the diagonal embedding is an isomorphism. By induction, we reduce to proving this for the map

$$\int^{[k]} Y_{k,k} \wedge \Delta^k_+ \longrightarrow \int^{[k_1]}\int^{[k_2]} Y_{k_1,k_2} \wedge \Delta^{k_1}_+ \wedge \Delta^{k_2}_+$$

for any bisimplicial object Y in Sp^Σ. Arguing levelwise, this follows at once from the fact that the geometric realization of a simplicial object in (pointed) simplicial sets is just given by its diagonal. □

Theorem 5.5.8. *The equivalence $\underline{\mathfrak{Sp}}_G \simeq \underline{\mathsf{Sp}}_G$ of G-∞-categories upgrades canonically to an equivalence $\underline{\mathfrak{Sp}}^\otimes_G \simeq \underline{\mathsf{Sp}}^\otimes_G$ of normed G-∞-categories.*

Proof. Of the maps of G-∞-categories comprising the diagram (15), all except for the lower one have been lifted to maps in $\mathsf{NAlg}_G(\mathsf{Cat}_\infty)$ above. As Σ^∞ is given by universally inverting representation spheres, and we have shown that they become invertible in $\underline{\mathsf{Sp}}_G$, there is then a unique normed pointwise left adjoint $\underline{\mathfrak{Sp}}^\otimes_G \to \underline{\mathsf{Sp}}^\otimes_G$ making the diagram commute. It only remains to show that this map forgets to our equivalence $\underline{\mathfrak{Sp}}_G \simeq \underline{\mathsf{Sp}}_G$.

For this we simply note that after forgetting to symmetric monoidal G-∞-categories there is still a unique map making the diagram commute, and we have lifted the equivalence $\underline{\mathfrak{Sp}}_G \simeq \underline{\mathsf{Sp}}_G$ to such a map in the proof of Proposition 5.5.6. □

5.6 The multiplicative equivariant recognition theorem

As an upshot of all the hard work done in the previous subsections, we can now easily prove Theorem A from the introduction:

Theorem 5.6.1.

(1) *The normed structure on* $\underline{\mathsf{NMon}}_G$ *localizes to a normed structure on* $\underline{\mathsf{NGrp}}_G$.

(2) *The normed structure on* $\underline{\mathfrak{Sp}}_G$ *restricts to a normed structure on the full G-subcategory* $\underline{\mathfrak{Sp}}_G^{\geq 0}$ *spanned by the connective equivariant spectra.*

(3) *The delooping functor* $\underline{\mathsf{NMon}}_G \to \underline{\mathfrak{Sp}}_G$ *acquires a canonical normed structure, and this restricts to a normed equivalence* $\underline{\mathsf{NGrp}}_G^{\otimes} \simeq (\underline{\mathfrak{Sp}}_G^{\geq 0})^{\otimes}$.

Proof. By Theorem 5.5.8, we may replace $\underline{\mathfrak{Sp}}_G$ by $\underline{\mathsf{Sp}}_G$; under this identification, the G-subcategory $\underline{\mathfrak{Sp}}_G^{\geq 0}$ corresponds to $\underline{\mathsf{Sp}}_G^{\geq 0} := \mathsf{Fun}(\mathsf{Span}((\mathbb{F}_G)_{/-}), \mathsf{Sp}^{\geq 0})$.

We now observe that the essential image of $\ell\colon \underline{\mathsf{NGrp}}_G \to \underline{\mathsf{Sp}}_G$ is precisely $\underline{\mathsf{Sp}}_G^{\geq 0}$. As we have lifted ℓ to a normed functor in Theorem 5.5.1, this shows that $\underline{\mathsf{Sp}}_G^{\geq 0}$ is indeed a normed subcategory. Since ℓ factors as the localization functor $\underline{\mathsf{NMon}}_G \to \underline{\mathsf{NGrp}}_G$ followed by an equivalence $\underline{\mathsf{NGrp}}_G \simeq \underline{\mathsf{Sp}}_G^{\geq 0}$, this then immediately implies the remaining statements. □

Corollary 5.6.2. *The cocartesian fibration* $\underline{\mathsf{NMon}}_G^{\otimes} \to \mathsf{Span}(\mathbb{F}_G)$ *restricts to a cocartesian fibration* $\underline{\mathsf{NGrp}}_G^{\otimes} \to \mathsf{Span}(\mathbb{F}_G)$*, and the inclusion* $\iota\colon \underline{\mathsf{NGrp}}_G^{\otimes} \hookrightarrow \underline{\mathsf{NMon}}_G^{\otimes}$ *is lax normed.*

Proof. For each $X \in \mathbb{F}_G$, the functor $\ell\colon \underline{\mathsf{NMon}}_G(X) \to \underline{\mathsf{Sp}}_G^{\geq 0}(X)$ has a fully faithful right adjoint, induced by the right adjoint $\mathsf{Sp}^{\geq 0} \to \mathsf{CMon}$ of the delooping functor, and this induces a relative adjunction of cocartesian fibrations over $\mathbb{F}_G^{\mathrm{op}}$. As a consequence of [Lur17, 7.3.2.6] (parallel to [Lur17, 7.3.2.8]), the right adjoint ι then canonically lifts to a lax normed functor $\iota^{\otimes}\colon (\underline{\mathsf{Sp}}_G^{\geq 0})^{\otimes} \hookrightarrow \underline{\mathsf{NMon}}_G^{\otimes}$, which is fully faithful with essential image the subcategory $\underline{\mathsf{NGrp}}_G$. □

We now immediately obtain the following generalization of Theorem B from the introduction:

Theorem 5.6.3. *For a weakly extensive subcategory* $I \subseteq \mathbb{F}_G$*, there is an equivalence between*

- *the* ∞*-category* $\mathsf{NAlg}_I((\underline{\mathfrak{Sp}}_G^{\geq 0})^{\otimes}) := \mathsf{NAlg}_{(\mathbb{F}_G, I)}((\underline{\mathfrak{Sp}}_G^{\geq 0})^{\otimes})$ *of connective* ***I-normed G-spectra****, and*
- *the* ∞*-category* $\mathsf{Tamb}_{(\mathbb{F}_G, I)}(\mathsf{Spc}) \subseteq \mathsf{Fun}^{\times}(\mathsf{Bispan}_I(\mathbb{F}_G), \mathsf{Spc})$ *of space-valued* $(\mathbb{F}_G, I)$*-Tambara functors.*

Proof. By Theorem 5.6.1, $\mathsf{NAlg}_{(\mathbb{F}_G,I)}((\underline{\mathfrak{Sp}}_G^{\geq 0})^{\otimes})$ is equivalent to $\mathsf{NAlg}_{(\mathbb{F}_G,I)}(\underline{\mathsf{NGrp}}_G^{\otimes})$. The inclusion $\mathsf{NAlg}_{(\mathbb{F}_G,I)}(\underline{\mathsf{NGrp}}_G^{\otimes}) \hookrightarrow \mathsf{NAlg}_{(\mathbb{F}_G,I)}(\underline{\mathsf{NMon}}_G^{\otimes}) = \mathsf{NRig}_{(\mathbb{F}_G,I)}(\mathsf{Spc})$ identifies its source with the subcategory $\mathsf{NRing}_{(\mathbb{F}_G,I)}(\mathsf{Spc}) \subseteq \mathsf{NRig}_{(\mathbb{F}_G,I)}(\mathsf{Spc})$ of normed G-rings in the ∞-category of spaces. By Theorem 4.3.6, the equivalence between $\mathsf{NRig}_{(\mathbb{F}_G,I)}(\mathsf{Spc}) \simeq \mathsf{Fun}^{\times}(\mathsf{Bispan}_I(\mathbb{F}_G), \mathsf{Spc})$ of Theorem 4.2.4 restricts to an equivalence between $\mathsf{NRing}_{(\mathbb{F}_G,I)}(\mathsf{Spc})$ and $\mathsf{Tamb}_{(\mathbb{F}_G,I)}(\mathsf{Spc})$. Combining these three equivalences gives the result. □

If $I \subseteq \mathbb{F}_G$ is even an extensive subcategory (i.e. an indexing system), then set-valued $(\mathbb{F}_G, I)$-Tambara functors are known under the name *incomplete Tambara functors* [BH18, 4.1]; thus, we may think of the right-hand side of the theorem as "higher" incomplete Tambara functors.

Remark 5.6.4. Let $I \subseteq \mathbb{F}_G$ be an indexing system and $\mathscr{C}^{\otimes}$ an I-normed G-∞-category. As we will now explain, the ∞-category $\mathsf{NAlg}_I(\mathscr{C})$ can be identified with that of algebras for the G-∞-operad $\mathrm{Com}_I^{\otimes}$ as defined by Nardin and Shah [NS22, 2.4.10]: By definition, the ∞-category $\mathsf{NAlg}_I(\mathscr{C}^{\otimes})$ is that of sections $\mathsf{Span}_I(\mathbb{F}_G) \to \mathscr{C}^{\otimes}$ that are cocartesian over $\mathbb{F}_G^{\mathrm{op}}$. Here the inclusion $\mathsf{Span}_I(\mathbb{F}_G) \to \mathsf{Span}(\mathbb{F}_G)$ exhibits $\mathsf{Span}_I(\mathbb{F}_G)$ as an equivariant ∞-operad when these are defined over the base $\mathsf{Span}(\mathbb{F}_G)$ (see [BHS22, §5.2]), and I-normed algebras in $\mathscr{C}^{\otimes}$ are precisely algebras for this ∞-operad. In [NS22] the theory of equivariant ∞-operads is instead developed over a different base $\underline{\mathbb{F}}_{G,*}$ (a specific model of the cocartesian unstraightening of the functor $\underline{\mathbb{F}}_{G,*}\colon \mathbb{F}_G \to \mathsf{Cat}_{\infty}$ considered above), but these two versions of G-∞-operads were shown to be equivalent under pullback along a certain functor $\underline{\mathbb{F}}_{G,*} \to \mathsf{Span}(\mathbb{F}_G)$ in [BHS22, 5.2.14]. It is clear from the definitions that $\mathrm{Com}_I^{\otimes}$ is precisely the pullback $\underline{\mathbb{F}}_{G,*} \times_{\mathsf{Span}(\mathbb{F}_G)} \mathsf{Span}_I(\mathbb{F}_G)$, so by [BHS22, 5.3.17] we get an equivalence between the ∞-category of $\mathsf{Span}_I(\mathbb{F}_G)$- and $\mathrm{Com}_I^{\otimes}$-algebras in $\mathscr{C}^{\otimes}$. In particular, our I-normed G-spectra are equivalently $\mathrm{Com}_I^{\otimes}$-algebras in $\underline{\mathsf{Sp}}_G^{\otimes}$ in the sense of [NS22].

Remark 5.6.5. Recall from Remark 3.1.5 that any indexing system $I \subseteq \mathbb{F}_G$ has an associated N_{∞}-operad $\mathcal{O}$ in G-spaces. It is generally expected that the ∞-category of $\mathrm{Com}_I^{\otimes}$-algebras in $\underline{\mathsf{Sp}}_G^{\otimes}$ is modelled by $\mathcal{O}$-algebras in a good model category of G-spectra, like G-symmetric spectra; however, to our knowledge no rigorous proof of this comparison has appeared in the literature.

A The Borel construction

In this appendix, we recall from [Hil22a] how any ∞-category with G-action gives rise to a G-∞-category and how similarly any symmetric monoidal ∞-category with G-action yields a normed G-∞-category.

A.1 Borel G-∞-categories

We start by constructing the functor

$$(-)^\flat \colon \mathsf{Fun}(BG, \mathsf{Cat}_\infty) \longrightarrow \mathsf{Fun}^\times(\mathbb{F}_G^{\mathrm{op}}, \mathsf{Cat}_\infty)$$

from ∞-categories with G-action to G-∞-categories, which is used, for instance, to define the G-∞-categories $\underline{\mathfrak{S}}_G$ and $\underline{\mathfrak{Sp}}_G$.

Construction A.1.1. Write $k\colon (BG)^{\mathrm{op}} \hookrightarrow \mathbb{F}_G$ for the inclusion of the full subcategory on the free G-set G. Then k is fully faithful, so $k^*\colon \mathsf{Fun}(\mathbb{F}_G^{\mathrm{op}}, \mathsf{Cat}_\infty) \to \mathsf{Fun}(BG, \mathsf{Cat}_\infty)$ has a fully faithful right adjoint $(-)^\flat$, which is uniquely characterized by demanding that we have a counit equivalence $\epsilon\colon k^*(-)^\flat \to \mathrm{id}$ and that each individual $\mathscr{C}^\flat$ be right Kan extended.

We will now give an explicit construction of $(-)^\flat$. For this we note that the inclusion $\mathsf{Fun}(BG, \mathsf{Spc}) \hookrightarrow \mathsf{Fun}(BG, \mathsf{Cat}_\infty)$ is cocontinuous, hence (by the universal property of presheaves) left Kan extended from the functor $(BG)^{\mathrm{op}} \to \mathsf{Fun}(BG, \mathsf{Cat}_\infty)$ classifying the right G-set G. Restricting to a full subcategory, we see that also the inclusion $i\colon \mathbb{F}_G \hookrightarrow \mathsf{Fun}(BG, \mathsf{Cat}_\infty)$ is left Kan extended from the same functor. Thus, $\mathsf{Fun}_G(i(-), \mathscr{C})$ is right Kan extended, and we see that $(-)^\flat$ is given by the assignment $\mathscr{C} \mapsto \mathsf{Fun}_G(i(-), \mathscr{C})$, where the right-hand side denotes the internal hom in $\mathsf{Fun}(BG, \mathsf{Cat}_\infty)$; the counit is the evident equivalence $\mathsf{Fun}_G(G, \mathscr{C}) \simeq \mathscr{C}$. Note that $(-)^\flat$ lands in the ∞-category $\mathsf{Fun}^\times(\mathbb{F}_G^{\mathrm{op}}, \mathsf{Cat}_\infty)$ of G-∞-categories, so that we obtain an adjunction

$$k^*\colon \mathsf{Fun}^\times(\mathbb{F}_G^{\mathrm{op}}, \mathsf{Cat}_\infty) \rightleftarrows \mathsf{Fun}(BG, \mathsf{Cat}_\infty) : (-)^\flat.$$

Definition A.1.2. We will refer to G-∞-categories in the essential image of $(-)^\flat$ as *Borel G-∞-categories*.

Remark A.1.3. In all of our examples, we apply the above right adjoint $(-)^\flat$ to an ordinary ∞-category, which is then to be understood as coming equipped with the trivial G-action. By adjointness, the resulting functor is given by

$$\begin{aligned} \mathsf{Cat}_\infty &\longrightarrow \mathsf{Fun}^\times(\mathbb{F}_G^{\mathrm{op}}, \mathsf{Cat}_\infty) \simeq \mathsf{Fun}(\mathbf{O}_G^{\mathrm{op}}, \mathsf{Cat}_\infty) \\ \mathscr{C} &\longmapsto \mathsf{Fun}(i(-)_{hG}, \mathscr{C}). \end{aligned}$$

In particular, the value of $\mathscr{C}^\flat$ on an orbit G/H is the ∞-category $\mathscr{C}^{BH} := \mathsf{Fun}(BH, \mathscr{C})$ of objects of $\mathscr{C}$ with an H-action, with the evident restriction functoriality. This suggests the following alternative description of the Borel G-∞-category $\mathscr{C}^\flat$ that connects it to the constructions of [CLL23a, CLL23b]:

Write Orb for the ∞-category of finite connected groupoids and faithful functors: in other words, the objects are groupoids of the form BH for a finite group H, and the morphisms $BK \to BH$ are those induced by *injective* group homomorphisms $K \to H$. By [CLL23b, 5.10] there is an equivalence $\mathbf{O}_G \simeq \mathsf{Orb}_{/BG}$ sending G to the homomorphism $1 \to BG$; postcomposing with the forgetful functor and the inclusion yields a functor $v\colon \mathbf{O}_G \to \mathsf{Cat}_\infty$. We claim that v agrees with $i(-)_{hG}$. For this we observe that both agree on the full subcategory spanned by the object G (where they are constant with value the terminal object), so it suffices that both are left Kan extended from this subcategory.

For $i(-)_{hG}$ this is clear since it is the restriction of a cocontinuous functor $\mathsf{Fun}(BG, \mathsf{Spc}) \to \mathsf{Cat}_\infty$. For v, it suffices that $\mathsf{Orb}_{/BG} \to \mathsf{Cat}_\infty$ is left Kan extended. But $\mathsf{Orb}_{/BG}$ is a full subcategory of $(\mathsf{Spc})_{/BG}$, so it will be enough that the forgetful functor $\mathsf{Spc}_{/BG} \to \mathsf{Cat}_\infty$ is left Kan extended from the full subcategory spanned by $1 \to BG$. However, straightening–unstraightening provides an equivalence $\mathsf{Spc}_{/BG} \simeq \mathsf{Fun}(BG, \mathsf{Spc})$ sending $1 \to BG$ to the corepresented functor $G = \mathsf{Map}_{BG}(*, -)$ so this follows again from cocontinuity.

A.2 Normed structures on Borel G-∞-categories

Recall from Definition 3.2.1 that a *normed structure* on a G-∞-category $\mathbb{F}_G^{\mathrm{op}} \to \mathsf{Cat}_\infty$ is an extension to a product-preserving functor $\mathsf{Span}(\mathbb{F}_G) \to \mathsf{Cat}_\infty$. Given a symmetric monoidal ∞-category $\mathscr{C}$ with G-action, the Borel G-∞-category $\mathscr{C}^\flat$ comes equipped with a canonical normed structure that we will refer to as the *Borel normed structure*:

Proposition A.2.1 ([Pü24, 3.4 and 3.6], [Hil22a, 3.3.3])**.** *The adjunction from Construction A.1.1 lifts to an adjunction*

$$\mathsf{Fun}^\times(\mathsf{Span}(\mathbb{F}_G), \mathsf{Cat}_\infty) \rightleftarrows \mathsf{Fun}(BG, \mathsf{CMon}(\mathsf{Cat}_\infty)) : (-)^\flat,$$

i.e. the forgetful functor $\mathsf{Fun}^\times(\mathsf{Span}(\mathbb{F}_G), \mathsf{Cat}_\infty) \to \mathsf{Fun}(BG, \mathsf{CMon}(\mathsf{Cat}_\infty))$ *has a right adjoint* $(-)^\flat$*, and the Beck–Chevalley transformation*

$$\begin{array}{ccc} \mathsf{Fun}(BG, \mathsf{CMon}(\mathsf{Cat}_\infty)) & \xrightarrow{(-)^\flat} & \mathsf{Fun}^\times(\mathsf{Span}(\mathbb{F}_G), \mathsf{Cat}_\infty) \\ {\scriptstyle \mathbb{U}}\downarrow & \swarrow\!\!\!\!\swarrow & \downarrow{\scriptstyle \mathbb{U}} \\ \mathsf{Fun}(BG, \mathsf{Cat}_\infty) & \xrightarrow[(-)^\flat]{} & \mathsf{Fun}^\times(\mathbb{F}_G^{\mathrm{op}}, \mathsf{Cat}_\infty) \end{array}$$

is invertible. □

Corollary A.2.2. *The right adjoint*

$$(-)^\flat\colon \mathsf{Fun}(BG, \mathsf{CMon}(\mathsf{Cat}_\infty)) \longrightarrow \mathsf{Fun}^\times(\mathsf{Span}(\mathbb{F}_G), \mathsf{Cat}_\infty)$$

is fully faithful, with essential image those normed G-∞-categories whose underlying G-∞-category is Borel.

Proof. As $\mathbb{U}$ is conservative, the Beck–Chevalley condition readily implies that the counit is invertible, as it is so for the original adjunction $\mathsf{Fun}^\times(\mathbb{F}_G^{\mathrm{op}}, \mathsf{Cat}_\infty) \rightleftarrows \mathsf{Fun}(BG, \mathsf{Cat}_\infty)$, proving full faithfulness. Arguing in the same way about the units yields the characterization of the essential image. □

Corollary A.2.3. *Let* $F\colon \mathsf{Fun}(BG, \mathsf{CMon}(\mathsf{Cat}_\infty)) \to \mathsf{Fun}^\times(\mathsf{Span}(\mathbb{F}_G), \mathsf{Cat}_\infty)$ *be any functor equipped with a natural equivalence* $\epsilon\colon \mathrm{ev}_G \circ F \to \mathrm{id}$*, and assume that* F *takes values in Borel* G*-*∞*-categories. Then* F *is right adjoint to the evaluation functor, with counit given by* ϵ*.*

Proof. By adjointness, there is a unique natural transformation $F \to (-)^\flat$ that upon evaluation at $G \in \mathbb{F}_G$ recovers ϵ. As this evaluation functor is conservative on Borel G-∞-categories, this map is then an equivalence as desired. ◻

In the same way one shows the following pointwise version:

Corollary A.2.4. *If the* G*-*∞*-category* $\mathscr{C}\colon \mathbb{F}_G^{\mathrm{op}} \to \mathsf{Cat}_\infty$ *is Borel, then any* G*-equivariant symmetric monoidal structure on* $\mathscr{C}(G) \in \mathsf{Fun}(BG, \mathsf{Cat}_\infty)$ *lifts uniquely to a normed structure on* $\mathscr{C}$*.* ◻

Observation A.2.5. If $\mathscr{C}$ is a symmetric monoidal ∞-category with G-action, then we get two natural symmetric monoidal structures on $\mathscr{C}^{hH} \simeq \mathscr{C}^\flat(G/H)$ for any $H \leqslant G$: on the one hand, we can equip $\mathscr{C}^{hH}$ with the symmetric monoidal structure obtained from the one on $\mathscr{C}$ by taking homotopy fixed points; on the other hand, we can restrict $\mathscr{C}^\flat$ along the functor $\mathsf{Span}(\mathbb{F}) \to \mathsf{Span}(\mathbb{F}_G)$ induced by $G/H \times -$. The Eckmann–Hilton argument then shows that these two structures agree, i.e. the covariant functoriality of $\mathscr{C}^\flat$ in fold maps is induced by the given symmetric monoidal structure by passing to homotopy fixed points.

A.3 The classical case

Let $\mathscr{C}$ be a symmetric monoidal ∞-category with G-action. So far, we have completely described the contravariant functoriality of $\mathscr{C}^\flat$, as well as the covariant functoriality with respect to fold maps. The goal of this final subsection is to provide the only missing piece of information, namely the covariant functoriality with respect to maps $G/K \to G/H$ for $K \leqslant H \leqslant G$, when $\mathscr{C}$ is a 1-category.

It turns out that the hardest part of this is actually not understanding the ∞-categorical side, but rather translating this back through the equivalence between (classical, biased) symmetric monoidal 1-categories and the ∞-category of commutative monoids in Cat [SS79, Sha20]. We therefore take a somewhat different route here: namely, we will give a general result characterizing the structure maps $\mathscr{C}^{hK} \to \mathscr{C}^{hH}$ uniquely, and then give a (classical) construction satisfying these assumptions. As an upshot, we will never need to recall *how* the functor Φ from symmetric monoidal 1-categories to symmetric monoidal ∞-categories actually works, except for the following basic facts:

- Φ is fully faithful with essential image those symmetric monoidal ∞-categories whose underlying category is a 1-category.
- Φ preserves underlying categories, and for every $\mathscr{C}$ the maps $* \to \mathscr{C}$ and $\mathscr{C}^{\times 2} \to \mathscr{C}$ obtained via the functoriality of $\Phi(\mathscr{C})$ in $\mathbf{0} \to \mathbf{1}$ and $\mathbf{2} \to \mathbf{1}$ are given by the inclusion of the unit and the tensor product, respectively.

For definiteness, we fix Φ to be the equivalence from [Sha20, 6.19] between $\mathsf{CMon}(\mathsf{Cat})$ and the ∞-category obtained from the 1-category $\mathsf{PermCat}_1^{\text{strict}}$ of *permutative categories* (i.e. symmetric monoidal categories in which associativity and unitality hold on the nose) and *strict* symmetric monoidal functors by Dwyer–Kan localizing at the underlying equivalences of categories. Below, we will frequently and implicitly extend Φ to the analogous localizations of the 1-categories $\mathsf{SymMonCat}_1^{\text{strict}}$ of symmetric monoidal categories and *strict* symmetric monoidal functors as well as $\mathsf{SymMonCat}_1^{\text{strong}}$ using the following reformulation of Mac Lane's coherence theorem, as refined symmetrically in [May74, 4.2]:

Lemma A.3.1. *The inclusions*

$$\mathsf{PermCat}_1^{\text{strict}} \hookrightarrow \mathsf{SymMonCat}_1^{\text{strict}} \hookrightarrow \mathsf{SymMonCat}_1^{\text{strong}}$$

induce equivalences on Dwyer–Kan localizations.

Proof. For the composite $\mathsf{PermCat}_1^{\text{strict}} \hookrightarrow \mathsf{SymMonCat}_1^{\text{strong}}$ this appears for example as [Len21, 1.19]. As part of the proof, the reference constructs a functor $\Pi\colon \mathsf{SymMonCat}_1^{\text{strong}} \to \mathsf{PermCat}_1^{\text{strict}}$ together with a natural *strong* symmetric monoidal equivalence $\nu\colon \mathscr{C} \to \Pi\mathscr{C}$ for any symmetric monoidal category $\mathscr{C}$. It will therefore suffice to show that there exists a natural zig-zag of *strict* symmetric monoidal equivalences between $\mathscr{C}$ and $\Pi\mathscr{C}$.

This is actually an instance of a general construction: Define $\Xi\mathscr{C}$ to be the category with objects triples of an object $X \in \mathscr{C}$, an object $Y \in \Pi\mathscr{C}$, and an isomorphism $\sigma\colon \nu(X) \xrightarrow{\sim} Y$. A morphism in $(X, Y, \sigma) \to (X', Y', \sigma')$ is given by a pair of a map $X \to X'$ and a map $Y \to Y'$ making the obvious diagram commute. This becomes a functor in $\mathscr{C}$ in the obvious way, and the forgetful maps provide natural equivalences $\mathscr{C} \xleftarrow{\sim} \Xi\mathscr{C} \xrightarrow{\sim} \Pi\mathscr{C}$.

We now make $\Xi\mathscr{C}$ into a symmetric monoidal category as follows: the tensor product of objects is given by

$$(X, Y, \sigma) \otimes (X', Y', \sigma') = \big(X \otimes X', Y \otimes Y', (\sigma \otimes \sigma') \circ \psi^{-1}\big)$$

where $\psi\colon \nu(X) \otimes \nu(X') \xrightarrow{\sim} \nu(X \otimes X')$ denotes the structure isomorphism of the symmetric monoidal functor ν. The unit is given by the inverse structure isomorphism $\nu(\mathbb{1}) \xrightarrow{\sim} \mathbb{1}$ of ν, while the tensor product of morphisms as well as the associativity, unitality, and symmetry isomorphisms for $\Xi\mathscr{C}$ are simply given pointwise. We omit the straightforward verification that this is well-defined and a symmetric monoidal category. It is then clear from the definitions that the projections $\mathscr{C} \leftarrow \Xi\mathscr{C} \to \Pi\mathscr{C}$ are strict symmetric monoidal. By direct inspection, they are still natural when considered as maps in $\mathsf{SymMonCat}_1^{\text{strong}}$, which then completes the proof of the lemma. ◻

We can now state our key technical lemma, whose proof will be given below after some preparations.

Proposition A.3.2. *Let $K \leqslant H \leqslant G$, and let $h_1, \ldots, h_r$ be orbit representatives for H/K. Then there exists a **unique** natural transformation*

$$\nu \colon \mathscr{C}^{hK} \longrightarrow \mathscr{C}^{hH}$$

of functors $\mathsf{Fun}(BG, \mathsf{SymMonCat}_1^{\mathrm{strict}}) \to \mathsf{Cat}$ *lifting* $\mathscr{C} \to \mathscr{C}, X \mapsto \bigotimes_{i=1}^r h_i.X$.

Example A.3.3. If $\mathscr{C}$ is any symmetric monoidal ∞-category with G-action, then the structure map $\mathscr{C}^\flat(G/K = G/K \to G/H) \colon \mathscr{C}^{hK} \to \mathscr{C}^{hH}$ lifts the twisted r-fold tensor product $X \mapsto \bigotimes_{i=1}^r h_i.X$: this follows at once by computing the composition

$$\begin{array}{ccccccc} & G/K & & & & G & \\ /\!\!/ & & \searrow & & \swarrow & & \backslash\!\!\backslash \\ G/K & & & G/H & & & G \end{array}$$

in $\mathsf{Span}(\mathbb{F}_G)$, cf. [Hil22a, 3.2.1].

Construction A.3.4. Let $\mathscr{C}$ be a symmetric monoidal 1-category with G-action. Recall that the *symmetric monoidal norm* $\mathrm{Nm}_K^H \colon \mathscr{C}^{hK} \to \mathscr{C}^{hH}$ is given as follows: we send a K-homotopy fixed point X (with structure isomorphisms $\phi_k \colon X \to k.X$) of $\mathscr{C}$ to $\bigotimes_{i=1}^r h_i.X$ with structure isomorphisms

$$\psi_h \colon \bigotimes_{i=1}^r h_i.X \longrightarrow \bigotimes_{i=1}^r hh_i.x$$

given as follows: if $\sigma \in \Sigma_n$ and $\ell_1, \ldots, \ell_r \in K$ satisfy $hh_i = h_{\sigma(i)}\ell_i$ for $i = 1, \ldots, r$, then ψ_h is given as the composite

$$\bigotimes_{i=1}^r h_i.X \xrightarrow{\sim} \bigotimes_{i=1}^r h_{\sigma(i)}.X \xrightarrow{\bigotimes h_{\sigma(i)}.\phi_{\ell_i}} \bigotimes_{i=1}^r h_{\sigma(i)}\ell_i.X = \bigotimes_{i=1}^r hh_i.x$$

where the unlabelled isomorphism is given by permuting the tensor factors according to σ; on morphisms, Nm_H^K is simply given by $f \mapsto \bigotimes_{i=1}^r h_i.f$.

We omit the straightforward but rather lengthy verification that this is well-defined. Note that this is clearly natural in *strict* symmetric monoidal functors, and hence also satisfies the assumptions of the proposition.

Observation A.3.5. If $\mathscr{C}$ carries the trivial G-action, the above construction simplifies as follows: the assignment $h \mapsto (\sigma; \ell_1, \ldots, \ell_r)$ defines a homomorphism $\iota \colon H \to \Sigma_r \wr K$, and the H-object $\mathrm{Nm}_K^H X$ is given by equipping $\bigotimes_{i=1}^r X$ with the restriction of the natural $\Sigma_r \wr K$-action on X (by permuting the factors and via the individual K-actions) along ι.

The uniqueness part of Proposition A.3.2 now immediately implies:

Corollary A.3.6. *Let $\mathscr{C}$ be a symmetric monoidal 1-category with G-action. Then the structure map $\mathscr{C}^{hK} = \mathscr{C}^\flat(G/K) \to \mathscr{C}^\flat(G/H) = \mathscr{C}^{hH}$ of the associated Borel G-∞-category is given by the classical symmetric monoidal norm of Construction A.3.4.* $\square$

It remains to prove the proposition.

Lemma A.3.7. *Let* $\mathbb{P}\colon \mathsf{Fun}(BG, \mathsf{Cat}_\infty) \to \mathsf{Fun}(BG, \mathsf{CMon}(\mathsf{Cat}_\infty))$ *denote the left adjoint of the forgetful functor. Then the restriction of* $\mathbb{P}$ *to* $\mathbb{F}_G$ *is given by* $X \mapsto (\mathbb{F}_{/X})^{\simeq}$*, with functoriality and* G*-action via postcomposition. The unit is given by* $X \to (\mathbb{F}_{/X})^{\simeq}, x \mapsto (x\colon \{*\} \to X)$.

Proof. Note that the claim is clear for $G = 1$ and $X = \{*\}$. For trivial G and general X, we now observe that since $\mathbb{P}$ is a left adjoint, it in particular preserves finite coproducts. As $\mathsf{CMon}(\mathsf{Cat}_\infty)$ is semiadditive, it therefore suffices that $\prod_{x\in X} \mathbb{F}_{/\{x\}} \simeq \mathbb{F}_{/X}$ via the coproduct functor, which is simply the statement that $\mathbb{F}$ is extensive.

This finishes the proof for trivial G. The lemma follows as the left adjoint for general G is simply given by taking the non-equivariant left adjoint and equipping it with the induced G-action. □

Proof of Proposition A.3.2. The existence of such a map was observed in Example A.3.3, so it only remains to prove uniqueness.

As both $(-)^{hK}$ and $(-)^{hH}$ preserve underlying equivalences of categories, we may replace the source by its Dwyer–Kan localization. Combining the above with [Len20, 4.1.36], we see that this localization is given by $\mathsf{Fun}(BG, \mathsf{CMon}(\mathsf{Cat}))$ (with the evident localization functor).

On the other hand, we observe that since the forgetful functor $\mathscr{C}^{hH} \to \mathscr{C}$ is faithful (here it is crucial that $\mathscr{C}$ is a 1-category!), a functor $f\colon \mathscr{C}^{hK} \to \mathscr{C}^{hH}$ is uniquely described by its effect on cores together with the composition $\mathscr{C}^{hK} \to \mathscr{C}^{hH} \to \mathscr{C}$. Thus, we are altogether reduced to showing that there is at most one natural transformation $((-)^{hK})^{\simeq} \to ((-)^{hH})^{\simeq}$ of functors $\mathsf{CMon}(\mathsf{Cat}) \to \mathsf{Spc}$ lifting the twisted r-fold tensor product.

Combining the Yoneda lemma with the representability result proven in Lemma A.3.7, this translates to saying that the object

$$\bigotimes_{i=1}^{r} h_i.(1 \longrightarrow G/K) \cong (H/K \hookrightarrow G/K)$$

of $\mathbb{F}^{\simeq}_{/(G/K)}$ admits at most one lift to an H-homotopy fixed point. But this is immediate since it admits no non-trivial automorphisms. □

Part IV

The global equivariant setting

PARAMETRIZED STABILITY AND THE UNIVERSAL PROPERTY OF GLOBAL SPECTRA

BASTIAAN CNOSSEN, TOBIAS LENZ, AND SIL LINSKENS

Abstract. We develop a framework of parametrized semiadditivity and stability with respect to so-called atomic orbital subcategories of an indexing ∞-category T, extending work of Nardin. Specializing this framework, we introduce *global ∞-categories* and the notions of equivariant semiadditivity and stability, yielding a higher categorical version of the notion of a Mackey 2-functor studied by Balmer-Dell'Ambrogio. As our main result, we identify the free presentable equivariantly stable global ∞-category with a natural global ∞-category of global spectra for finite groups, in the sense of Schwede and Hausmann.

Contents

1. Introduction

Equivariant homotopy theory combines classical homotopy theory with ideas from representation theory to study geometric objects with symmetries. Many constructions from homotopy theory carry over to the equivariant setting, leading for example to equivariant analogues of important cohomology theories like topological K-theory and (stable) bordism. The resulting tools and methods have been successfully applied to various other branches of mathematics, for example in the proof of the *Atiyah-Segal Completion Theorem* [AS69], Carlson's proofs of the *Segal* [Car84] and *Sullivan Conjecture* [Car91], or in the resolution of the Kervaire invariant one problem by Hill, Hopkins, and Ravenel [HHR16].

While one can study equivariant homotopy theory for a single group G at a time, there are many equivariant phenomena which occur uniformly and compatibly in large families of groups, such as the families of all finite groups or all compact Lie groups. The study of such phenomena is known as *global homotopy theory* [GH07, Boh14, Sch18, Hau19, Len20, LNP22]. This framework has led to improved understanding of a variety of equivariant phenomena, where previously a direct description for each individual group was either much more opaque or not available, for example for equivariant stable bordism and equivariant formal group laws [Hau22]. The study of global homotopy theory moreover admits connections to the geometry of stacks [GH07, Jur20, Par20, SS20].

Just like non-equivariant and G-equivariant homotopy theory, global homotopy theory comes in various different flavours: *unstable global homotopy theory* studies *global spaces* [GH07] while *stable global homotopy theory* is concerned with so-called *global spectra* [Sch18]; in-between, one can also consider a variety of algebraic structures on global spaces [Bar21], with the most prominent example being *ultra-commutative monoids* or the equivalent notion of *special global* Γ*-spaces* [Len20]. The goal of this article is to understand the relationship between these different variants.

Stability and equivariant semiadditivity. Classically the passage from the homotopy theory of spaces to the homotopy theory of spectra is known as *stabilization.* More generally, a homotopy theory $\mathcal{C}$ (e.g. given in the form of a model category or an ∞-category) is said to be *stable* if it is pointed and the suspension-loop adjunction in $\mathcal{C}$ is an equivalence. Stability of a homotopy theory leads to a lot of algebraic structure: for example, its homotopy category $\mathrm{Ho}(\mathcal{C})$ is additive, and it canonically admits the structure of a triangulated category. If $\mathcal{C}$ is not yet (known to be) stable, there is a universal way to stabilize it by forming a homotopy theory $\mathrm{Sp}(\mathcal{C})$ of suitable *spectrum objects* in $\mathcal{C}$.

Although one may apply this stabilization procedure to the homotopy theory of global spaces, the resulting theory is in many ways not sufficient, and in particular does not yield the homotopy theory of global spectra. This issue in fact already arises in the case of equivariant homotopy theory for a fixed group G: applying the general stabilization procedure to the homotopy theory of G-spaces for some finite group G only results in the homotopy theory of *naive G-spectra*, which for example does not support a good theory of duality. Instead, one defines the homotopy theory of *genuine G-spectra* by stabilizing more generally with respect to the *representation spheres* S^V for each finite-dimensional G-representation V. This genuine stabilization leads to a much richer algebraic structure on the associated homotopy category than naive stabilization: for example, the homotopy category of genuine G-spectra admits a canonical enrichment in *Mackey functors*, refining the enrichment in abelian groups.

Non-equivariantly, the algebraic structure on hom sets in a stable homotopy theory comes from semiadditivity: finite coproducts agree with finite products. In a similar way, the Mackey enrichment of the homotopy theory of genuine G-spectra comes from a form of *equivariant semiadditivity.* To explain what this means, consider a subgroup H of the finite group G; the restriction functor from genuine G-spectra to genuine H-spectra then admits both a left adjoint ind_H^G and a right adjoint coind_H^G, called *induction* and *coinduction*, respectively. From the perspective of this article, the main feature of genuine equivariant spectra is that there is a natural equivalence $\mathrm{ind}_H^G \simeq \mathrm{coind}_H^G$ between these two functors, called the *Wirthmüller isomorphism* [Wir74]. If we think of ind_H^G as a 'G-coproduct over G/H' and coind_H^G as a 'G-product over G/H,' this may be seen as an equivariant analogue of the usual notion of semiadditivity. These Wirthmüller isomorphisms are then precisely what gives rise to the transfer maps in the aforementioned Mackey enrichment.

Parametrized higher category theory. In light of the above, it is natural to ask whether one can modify the stabilization procedure for G-spaces in a way that additionally enforces equivariant semiadditivity, and, if so, whether this will result in the homotopy theory of genuine G-spectra. One subtlety with this question is that the Wirthmüller isomorphisms described above do not only depend on the homotopy theory of genuine G-spectra but also on the homotopy theories of genuine

H-spectra for every subgroup H of G, together with all the restriction functors relating them. Based on suggestions by Mike Hill in 2012, Clark Barwick, Emanuele Dotto, Saul Glasman, Denis Nardin, and Jay Shah [BDG+16] began developing the theory of *G-∞-categories* for a finite group G, in which these ideas could be made precise. More generally, given an ∞-category T, they introduced the notion of a *T-∞-category*, thought of as an family of ∞-categories parametrized by T, and showed that many concepts and foundational results from the theory of ∞-categories have analogues in this parametrized setting. Using this framework, Nardin [Nar16] worked out a notion of *parametrized semiadditivity* which neatly recovers the equivariant Wirthmüller isomorphisms described earlier. He further sketched a proof that the G-∞-category of genuine G-spectra is obtained from the G-∞-category of G-spaces by enforcing both stability and parametrized semiadditivity.

1.1. **Global ∞-categories.** The goal of this article is to develop an analogue of the above story, and in particular of Nardin's result, in the global setting. A distinguishing feature that was not present in the equivariant setting is the appearance of *inflation functors*: restriction functors along *surjective* group homomorphisms $\alpha\colon H \twoheadrightarrow G$. This extra structure leads to the notion of a *global ∞-category.* Roughly speaking, such an object consists of

(i) an ∞-category $\mathcal{C}(G)$ for every finite group G;
(ii) a restriction functor $\alpha^*\colon \mathcal{C}(G) \to \mathcal{C}(H)$ for every homomorphism $\alpha\colon H \to G$;
(iii) higher structure which in particular witnesses that conjugations act as the identity.

Examples of global ∞-categories abound in representation theory, and more generally equivariant mathematics; here we only mention categories of representations, genuine equivariant spectra, and equivariant Kasparov categories, referring the reader to [BD20] for a detailed discussion of these examples. In this paper, on the other hand, we will be mainly interested in examples coming from *G-global homotopy theory* in the sense of [Len20]; namely, we consider:

- the global ∞-category $\underline{\mathscr{S}}^{\mathrm{gl}}$ of *global spaces*, given at a group G by G-global spaces (see Section 3.2 for a precise definition);
- the global ∞-category $\underline{\Gamma\mathscr{S}}^{\mathrm{gl,\ spc}}$ of *special global Γ-spaces*, given at a group G by special G-global Γ-spaces (see Section 5.1 for a precise definition);
- the global ∞-category $\underline{\mathscr{S}p}^{\mathrm{gl}}$ of *global spectra*, given at a group G by G-global spectra (see Section 7.1 for a precise definition).

As the main results of this paper we establish universal properties for these three global ∞-categories:

Presentability. A global ∞-category $\mathcal{C}$ is said to be *presentable* if $\mathcal{C}(G)$ is presentable for all G and the restriction functors $\alpha^*\colon \mathcal{C}(G) \to \mathcal{C}(H)$ admit left and right adjoints $a_!$ and α_* for all $\alpha\colon H \to G$ satisfying a base change condition, which may be thought of as a categorified version of the Mackey double coset formula. We refer to Section 2.4 for a precise definition. The universal example is provided by G-global homotopy theory:

Theorem A (Universal property of global spaces, 3.3.2)**.** The global ∞-category $\underline{\mathscr{S}}^{\mathrm{gl}}$ is presentable. For every presentable global ∞-category $\mathcal{D}$, evaluation at the point $* \in \underline{\mathscr{S}}^{\mathrm{gl}}(1)$ induces an equivalence

$$\underline{\mathrm{Fun}}^{\mathrm{L}}_{\mathrm{Glo}}(\underline{\mathscr{S}}^{\mathrm{gl}}, \mathcal{D}) \to \mathcal{D}$$

of global ∞-categories. Put differently, $\underline{\mathscr{S}}^{\mathrm{gl}}$ is the free presentable global ∞-category on one generator $*$.

We will in fact provide a stronger version of Theorem A based on a notion of *global cocompleteness*, see Section 2.3. Our proof of this result can be regarded as a highly coherent version of Schwede's global Elmendorf theorem [Sch20].

Equivariant semiadditivity. Following ideas of [Nar16], we introduce a notion of *equivariant semiadditivity* in our context; namely, a global ∞-category $\mathcal{C}$ is equivariantly semiadditive if the following conditions are satisfied:

- *Fiberwise semiadditivity:* The ∞-category $\mathcal{C}(G)$ is semiadditive for every G and the functor $\alpha^*\colon \mathcal{C}(G) \to \mathcal{C}(H)$ preserves finite biproducts for every $\alpha\colon H \to G$;
- *Ambidexterity:* For every *injective* homomorphism $i\colon H \to G$, the restriction functor $i^*\colon \mathcal{C}(G) \to \mathcal{C}(H)$ admits a both left adjoint $i_!$ and a right adjoint i_* satisfying a base change condition as before, and a certain *norm map* $\mathrm{Nm}_i\colon i_! \to i_*$ is a natural equivalence between these two adjoints.

A 2-categorical analogue of this definition was studied under the name *Mackey 2-functor* by Balmer-Dell'Ambrogio [BD20]. The examples of representations, equivariant spectra, and Kasparov categories referred to above are all equivariantly semiadditive – for example, in the case of equivariant spectra, ambidexterity precisely comes from the Wirthmüller isomorphism. Once again, G-global homotopy theory provides the universal example in this setting:

Theorem B (Universal property of global Γ-spaces, 5.3.5)**.** The global ∞-category $\underline{\Gamma\mathscr{S}}^{\mathrm{gl,\ spc}}$ is presentable and equivariantly semiadditive. For every presentable equivariantly semiadditive global ∞-category $\mathcal{D}$, evaluation at the free special global Γ-space $\mathbb{P}(*)$ induces an equivalence

$$\underline{\mathrm{Fun}}^{\mathrm{L}}_{\mathrm{Glo}}(\underline{\Gamma\mathscr{S}}^{\mathrm{gl,\ spc}}, \mathcal{D}) \xrightarrow{\simeq} \mathcal{D}$$

of global ∞-categories. Put differently, $\underline{\Gamma\mathscr{S}}^{\mathrm{gl,\ spc}}$ is the free presentable equivariantly semiadditive global ∞-category on one generator $\mathbb{P}(*)$.

Equivariant stability. A global ∞-category $\mathcal{C}$ is called *equivariantly stable* if it is equivariantly semiadditive and *fiberwise stable*, meaning that the ∞-category $\mathcal{C}(G)$ is stable for every finite group G and the restriction functors $\alpha^*\colon \mathcal{C}(G) \to \mathcal{C}(H)$ are exact for all $\alpha\colon H \to G$.

Theorem C (Universal property of global spectra, 7.3.2)**.** The global ∞-category $\underline{\mathscr{S}p}^{\mathrm{gl}}$ is presentable and equivariantly stable. For every presentable equivariantly stable global ∞-category $\mathcal{D}$, evaluation at the global sphere spectrum $\mathbb{S}$ defines an equivalence

$$\underline{\mathrm{Fun}}^{\mathrm{L}}_{\mathrm{Glo}}(\underline{\mathscr{S}p}^{\mathrm{gl}}, \mathcal{D}) \xrightarrow{\simeq} \mathcal{D}$$

of global ∞-categories. Put differently, $\underline{\mathscr{S}p}^{\mathrm{gl}}$ is the free presentable equivariantly stable global ∞-category on one generator $\mathbb{S}$.

Combining this with Theorem A, this makes precise that $\underline{\mathscr{S}p}^{\mathrm{gl}}$ is obtained from $\underline{\mathscr{S}}^{\mathrm{gl}}$ by universally stabilizing and enforcing Wirthmüller isomorphisms, answering the question from the beginning. In particular, global ∞-categories provide a natural and convenient home for studying global homotopy theory. Conversely, once one is interested in global ∞-categories, global (and more generally G-global) homotopy theory appears naturally in the form of the universal examples. For example one can show using the above that for every equivariantly stable global ∞-category $\mathcal{C}$, the ∞-category $\mathcal{C}(G)$ is canonically enriched over G-global spectra, with strong compatibilities as the group G varies.

1.2. **Parametrized higher category theory.** In setting up the formalism of equivariant semiadditivity and stability, we work in the more general context of T-∞-categories for an arbitrary ∞-category T, in the sense of [BDG$^+$16]. Global ∞-categories arise as the special case where T is the $(2,1)$-category Glo of finite connected groupoids, see Example 2.1.3. We introduce the notion of an *atomic orbital* subcategory $P \subseteq T$, generalizing a notion due to [Nar16]; in this setting, we can then more generally define *P-semiadditivity* and *P-stability*, which for the subcategory Orb $\subseteq$ Glo of *faithful morphisms* specializes to the notions of equivariant semiadditivity/stability discussed before.

Given a T-∞-category $\mathcal{C}$ with sufficiently many parametrized limits, we provide a universal way to turn it into a P-semiadditive T-∞-category by passing to the T-∞-category $\underline{\mathrm{CMon}}^P(\mathcal{C})$ of *P-commutative monoids*, a parametrized version of commutative monoid objects in higher algebra. In a similar way, we construct a universal P-stabilization $\underline{\mathrm{Sp}}^P(\mathcal{C})$ of $\mathcal{C}$. Combining this with Theorem A, the key step in the proof of Theorem B and Theorem C is then to produce equivalences of global ∞-categories

$$\underline{\Gamma\mathscr{S}}^{\mathrm{gl,spc}} \simeq \underline{\mathrm{CMon}}^{\mathrm{Orb}}(\underline{\mathscr{S}}^{\mathrm{gl}}), \qquad \underline{\mathscr{S}p}^{\mathrm{gl}} \simeq \underline{\mathrm{Sp}}^{\mathrm{Orb}}(\underline{\mathscr{S}}^{\mathrm{gl}}).$$

1.3. **Acknowledgements.** The authors would like to thank Branko Juran for pointing out an omission in a draft of this article, which led to the inclusion of Appendix A. B.C. would like to thank Louis Martini and Sebastian Wolf for many helpful discussions about parametrized higher category theory. T.L. would like to thank Markus Hausmann who first suggested to him to use G-global homotopy theory to obtain the parametrized incarnation of global homotopy theory.

This article is partially based on work supported by the Swedish Research Council under grant no. 2016-06596 while T.L. was in residence at Institut Mittag-Leffler in Djursholm, Sweden in early 2022. B.C. and S.L. are associate members of the Hausdorff Center for Mathematics at the University of Bonn. B.C. is supported by the Max Planck Institute for Mathematics in Bonn. S.L. is supported by the DFG Schwerpunktprogramm 1786 "Homotopy Theory and Algebraic Geometry" (project ID SCHW 860/1-1).

2. Parametrized higher category theory

In this section, we will recall some of the basic notions of parametrized higher category theory. A first development of such theory was given by Clark Barwick, Emanuele Dotto, Saul Glasman, Denis Nardin and Jay Shah, cf. [BDG$^+$16, Sha21, Nar16]. From the perspective of categories internal to ∞-topoi, an alternative development was given by Louis Martini and Sebastian Wolf [Mar21, MW21, MW22].

2.1. T-∞-categories.

We introduce the notion of a T-∞-category for a small ∞-category T and discuss various constructions and examples.

Definition 2.1.1. Let T be a small ∞-category. A *T-∞-category* is a functor $\mathcal{C}\colon T^{\mathrm{op}} \to \mathrm{Cat}_\infty$. If $\mathcal{C}$ and $\mathcal{D}$ are T-∞-categories, then a *T-functor* $F\colon \mathcal{C} \to \mathcal{D}$ is a natural transformation from $\mathcal{C}$ to $\mathcal{D}$. The ∞-category Cat_T of T-∞-categories is defined as the functor category $\mathrm{Cat}_T := \mathrm{Fun}(T^{\mathrm{op}}, \mathrm{Cat}_\infty)$.

If $\mathcal{C}$ is a T-∞-category and $f\colon A \to B$ is a morphism in T, we will write f^* for the functor $\mathcal{C}(f)\colon \mathcal{C}(B) \to \mathcal{C}(A)$ and refer to this as *restriction along f*.

Example 2.1.2. Let G be a finite group and let Orb_G denote the *orbit category of G*, defined as the full subcategory of the category of G-sets spanned by the orbits G/H for subgroups $H \leqslant G$. When $T = \mathrm{Orb}_G$, T-∞-categories are referred to as *G-∞-categories*, c.f. [BDG$^+$16].

We will be mainly interested in the following example.

Example 2.1.3. Define **Glo** as the strict $(2,1)$-category of finite groups, group homomorphisms, and conjugations. In particular, **Glo** comes with a fully faithful functor $B\colon \mathbf{Glo} \hookrightarrow \mathbf{Grpd}$ into the $(2,1)$-category of groupoids given by sending a finite group G to the corresponding 1-object groupoid BG, a homomorphism $f\colon G \to H$ to the functor $Bf\colon BG \to BH$ given on homomorphisms by f, and a conjugation $h\colon f \Rightarrow f'$ (i.e. an $h \in H$ such that $f'(g) = hf(g)h^{-1}$ for all $g \in G$) to the natural transformation $Bf \Rightarrow Bf'$ whose value at the unique object of BG is the edge h.

We define the ∞-category Glo as the Duskin nerve of the $(2,1)$-category **Glo**. We will use the term *global ∞-category* for a Glo-∞-category, *global functor* for a Glo-functor, etc.

Remark 2.1.4. The straightening-unstraightening equivalence (see [Lur09, Theorem 3.2.0.1]) provides an equivalence of ∞-categories $\mathrm{Cat}_T \simeq (\mathrm{Cat}_\infty)^{\mathrm{cocart}}_{/T^{\mathrm{op}}}$, where $(\mathrm{Cat}_\infty)^{\mathrm{cocart}}_{/T^{\mathrm{op}}}$ denotes the (non-full) subcategory of the slice $(\mathrm{Cat}_\infty)_{/T^{\mathrm{op}}}$ spanned by the cocartesian fibrations over T^{op} and the functors over T^{op} that preserve cocartesian edges. The cocartesian fibration over T^{op} corresponding to a T-∞-category $\mathcal{C}\colon T^{\mathrm{op}} \to \mathrm{Cat}_\infty$ is denoted by $\int \mathcal{C} \to T^{\mathrm{op}}$ and is referred to as the cocartesian unstraightening of $\mathcal{C}$. A T-functor $F\colon \mathcal{C} \to \mathcal{D}$ corresponds to a functor $\int F\colon \int \mathcal{C} \to \int \mathcal{D}$ over T^{op} which preserves cocartesian edges. In fact, in the articles [BDG$^+$16], [Sha21] and [Nar16], a T-∞-category is *defined* as a cocartesian fibration over T^{op}.

Definition 2.1.5. Let $\mathcal{C}\colon T^{\mathrm{op}} \to \mathrm{Cat}_\infty$ be a T-∞-category. We define the *underlying ∞-category* $\Gamma(\mathcal{C})$ of $\mathcal{C}$ as the limit of $\mathcal{C}$:

$$\Gamma(\mathcal{C}) := \lim_{B \in T^{\mathrm{op}}} \mathcal{C}(B).$$

This defines a functor $\Gamma\colon \mathrm{Cat}_T \to \mathrm{Cat}_\infty$. Note that when T has a final object, $\Gamma(\mathcal{C})$ is obtained by evaluating $\mathcal{C}$ at the final object.

Remark 2.1.6. By [Lur09, Corollary 3.3.3.2], the ∞-category $\Gamma(\mathcal{C})$ is equivalent to the ∞-category of cocartesian sections of $\int \mathcal{C} \to T^{\mathrm{op}}$.

We discuss some important examples of T-∞-categories.

Example 2.1.7. Every ∞-category $\mathcal{E}$ gives rise to a T-∞-category $\mathrm{const}_{\mathcal{E}}\colon T^{\mathrm{op}} \to \mathrm{Cat}_\infty$ given by $\mathrm{const}_{\mathcal{E}}(t) = \mathcal{E}$ for all $t \in T$. This provides a functor $\mathrm{const}\colon \mathrm{Cat}_\infty \to \mathrm{Cat}_T$. We will refer to T-∞-categories in the essential image of this functor as *constant T-∞-categories.*

Remark 2.1.8. Note that the functor $\mathrm{const}\colon \mathrm{Cat}_\infty \to \mathrm{Cat}_T$ is left adjoint to the underlying ∞-category functor $\Gamma\colon \mathrm{Cat}_T \to \mathrm{Cat}_\infty$: for every T-∞-category $\mathcal{C}$ and every ∞-category $\mathcal{E}$ there is an equivalence

$$\mathrm{Hom}_{\mathrm{Cat}_T}(\mathrm{const}_{\mathcal{E}}, \mathcal{C}) \simeq \mathrm{Hom}_{\mathrm{Cat}_\infty}(\mathcal{E}, \Gamma(\mathcal{C})).$$

Example 2.1.9. Every presheaf $B\colon T^{\mathrm{op}} \to \mathrm{Spc}$ on T gives rise to a T-∞-category $\underline{B}\colon T^{\mathrm{op}} \to \mathrm{Cat}_\infty$ by composing it with the inclusion $\mathrm{Spc} \subseteq \mathrm{Cat}_\infty$ of ∞-groupoids into all ∞-categories, and we obtain a fully faithful inclusion

$$\mathrm{PSh}(T) = \mathrm{Fun}(T^{\mathrm{op}}, \mathrm{Spc}) \hookrightarrow \mathrm{Fun}(T^{\mathrm{op}}, \mathrm{Cat}_\infty) = \mathrm{Cat}_T\,.$$

The T-∞-categories in the essential image of this functor will be referred to as *T-∞-groupoids.*

In particular, every object $B \in T$ gives rise to a T-∞-category $\underline{B}$ via the Yoneda embedding $T \hookrightarrow \mathrm{PSh}(T)$.

Remark 2.1.10. The inclusion $\mathrm{PSh}(T) \subseteq \mathrm{Cat}_T$ admits a right adjoint $\iota\colon \mathrm{Cat}_T \to \mathrm{PSh}(T)$. It is given on $\mathcal{C}$ by $\iota \circ \mathcal{C}$, where $\iota\colon \mathrm{Cat}_\infty \to \mathrm{Spc}$ is the functor which assigns to an ∞-category its core, the largest ∞-groupoid contained in it.

Example 2.1.11. Let $\mathcal{E}$ be an ∞-category. A *T-object in $\mathcal{E}$* is a functor $T^{\mathrm{op}} \to \mathcal{E}$. We obtain a T-∞-category $\underline{\mathcal{E}}_T$ of *T-objects in $\mathcal{E}$* by assigning to an object $B \in T$ the ∞-category $\mathrm{Fun}((T_{/B})^{\mathrm{op}}, \mathcal{E})$ of $T_{/B}$-objects in $\mathcal{E}$. More precisely, the T-∞-category $\underline{\mathcal{E}}_T$ is defined as the following composite

$$T^{\mathrm{op}} \xrightarrow{B \mapsto (T_{/B})^{\mathrm{op}}} (\mathrm{Cat}_\infty)^{\mathrm{op}} \xrightarrow{\mathrm{Fun}(-,\mathcal{E})} \mathrm{Cat}_\infty,$$

where the functoriality of the first functor is via post-composition in T, i.e. the straightening of the cocartesian fibration $\mathrm{ev}_1\colon T^{[1]} \to T$. It is clear that sending $\mathcal{E}$ to $\underline{\mathcal{E}}_T$ gives rise to a functor $\mathrm{Cat}_\infty \to \mathrm{Cat}_T$.

As a special case, we obtain the following T-∞-categories:

(1) taking $\mathcal{E} = \mathrm{Spc}$ gives a T-∞-category $\underline{\mathrm{Spc}}_T$ of *T-spaces* or *T-∞-groupoids.*
(2) taking $\mathcal{E} = \mathrm{Spc}_*$ gives a T-∞-category $\underline{\mathrm{Spc}}_{T,*} \coloneqq \underline{\mathrm{Spc}_*}_T$ of *pointed T-spaces.*
(3) taking $\mathcal{E} = \mathrm{Sp}$ gives a T-∞-category $\underline{\mathrm{Sp}}_T$ of *naive T-spectra.*[1]
(4) taking $\mathcal{E} = \mathrm{cat}_\infty$, the ∞-category of small ∞-categories, gives a T-∞-category $\underline{\mathrm{cat}}_T \coloneqq \underline{\mathrm{cat}_\infty}_T$ of *small T-∞-categories.*

Remark 2.1.12. For every T-∞-category $\mathcal{C}$ and every ∞-category $\mathcal{E}$, there is an equivalence

$$\mathrm{Hom}_{\mathrm{Cat}_T}(\mathcal{C}, \underline{\mathcal{E}}_T) \simeq \mathrm{Hom}_{\mathrm{Cat}_\infty}(\textstyle\int \mathcal{C}, \mathcal{E})$$

which is natural in $\mathcal{C}$ and $\mathcal{E}$. In other words, the construction of Example 2.1.11 provides a right adjoint to the cocartesian unstraightening $\int\colon \mathrm{Cat}_T \to \mathrm{Cat}_\infty$ which

[1]The term 'naive spectra' is used in equivariant homotopy theory to contrast it with 'genuine spectra'.

assigns to a T-∞-category $\mathcal{C}\colon T^{\mathrm{op}} \to \mathrm{Cat}_\infty$ the total category $\int \mathcal{C}$ of its unstraightening $\int \mathcal{C} \to T^{\mathrm{op}}$. We will prove this in Lemma 2.2.13 below.

Remark 2.1.13. One may alternatively describe T-∞-categories as Cat_∞-valued sheaves on the presheaf ∞-topos $\mathrm{PSh}(T) = \mathrm{Fun}(T^{\mathrm{op}}, \mathrm{Spc})$, i.e., as limit-preserving functors $\mathrm{PSh}(T)^{\mathrm{op}} \to \mathrm{Cat}_\infty$. Indeed, the functor

$$\mathrm{Fun}(\mathrm{PSh}(T)^{\mathrm{op}}, \mathrm{Cat}_\infty) \to \mathrm{Fun}(T^{\mathrm{op}}, \mathrm{Cat}_\infty)$$

given by precomposition with the Yoneda embedding $T \hookrightarrow \mathrm{PSh}(T)$ becomes an equivalence when restricting the domain to the full subcategory of limit-preserving functors, see [Lur09, Theorem 5.1.5.6].

Remark 2.1.14. For an ∞-topos $\mathcal{B}$, the ∞-category $\mathrm{Fun}^{\mathrm{R}}(\mathcal{B}^{\mathrm{op}}, \mathrm{Cat}_\infty)$ of sheaves of ∞-categories on $\mathcal{B}$ is equivalent to the full subcategory of $\mathrm{Fun}(\Delta^{\mathrm{op}}, \mathcal{B})$ spanned by the *internal ∞-categories* (or *complete Segal objects*). We refer to [Mar21, Definition 3.2.4] for a precise definition of an internal ∞-category, and to [Mar21, Section 3.5] for a proof of this equivalence. By Remark 2.1.13, the study of T-∞-categories is thus equivalent to the study of ∞-categories internal to the presheaf topos $\mathrm{PSh}(T)$. Although we will never use this perspective in this article, we will not hesitate to cite results from [Mar21, MW21, MW22] which are formulated in the language of internal ∞-categories.

Convention 2.1.15. Henceforth, we will abuse notation and denote the extension of a T-∞-category $\mathcal{C}$ to a limit preserving functor $\mathrm{PSh}(T)^{\mathrm{op}} \to \mathrm{Cat}_\infty$ again by $\mathcal{C}$. At various points in this article, we will write expressions such as $A \times A$ or $A \times_B A$ for objects $A, B \in T$, meaning implicitly that this pullback is taken in the presheaf ∞-category $\mathrm{PSh}(T)$. In particular, when we write $\mathcal{C}(A \times B)$ or $\mathcal{C}(A \times_B A)$, we are referring to the values of the limit-extension $\mathcal{C}\colon \mathrm{PSh}(T)^{\mathrm{op}} \to \mathrm{Cat}_\infty$ at the relevant objects. This abuse of notation is justified by the fact that the Yoneda embedding $T \hookrightarrow \mathrm{PSh}(T)$ preserves all limits that exist in T, cf. [Lur09, Proposition 5.1.3.2]. In a similar way, all colimits of objects of T are understood to be taken in the presheaf ∞-category $\mathrm{PSh}(T)$: expressions such as $\coprod_{i=1}^n A_i$ will always mean formal disjoint union.

Remark 2.1.16. It will be useful to observe that the limit-extension of the T-∞-category $\underline{\mathrm{Spc}}_T$ of T-spaces is equivalent to the slice functor

$$\begin{aligned} \mathrm{PSh}(T)_{/-}\colon \mathrm{PSh}(T)^{\mathrm{op}} &\to \mathrm{Cat}_\infty, \\ A &\mapsto \mathrm{PSh}(T)_{/A}, \\ [f\colon A \to B] &\mapsto f^*\colon \mathrm{PSh}(T)_{/B} \to \mathrm{PSh}(T)_{/A}, \end{aligned}$$

which is defined as the functor which classifies the cartesian fibration

$$t\colon \mathrm{Ar}(\mathrm{PSh}(T)) \to \mathrm{PSh}(T)\colon (A \to B) \mapsto B.$$

Indeed, since this slice functor preserves limits by [Lur09, Theorem 6.1.3.9, Proposition 6.1.3.10], it suffices to show that its restriction to T^{op} is equivalent to $\underline{\mathrm{Spc}}_T$. Consider the Yoneda embedding $T \hookrightarrow \mathrm{PSh}(T)$. By considering the functoriality in over-categories on both sides we obtain a natural transformation

$$T_{/-} \to \mathrm{PSh}(T)_{/-}$$

of functors in T. The universal property of presheaves implies that this extends to a natural equivalence

$$\mathrm{PSh}(T_{/-}) \xrightarrow{\sim} \mathrm{PSh}(T)_{/-}.$$

By the naturality of the Yoneda embedding (see [HHLN22b, Theorem 8.1] or [Ram22, Theorem 2.4]) we get that upon passing to right adjoints the diagram $\mathrm{PSh}(T_{/-})$ agrees with $\underline{\mathrm{Spc}}_T$, completing the proof.

Example 2.1.17. For an object $B \in T$ there is an adjunction

$$\pi_B \colon \mathrm{PSh}(T)_{/B} \rightleftarrows \mathrm{PSh}(T) : - \times B,$$

where π_B is the forgetful functor. Since both functors preserve colimits we obtain by precomposition an adjunction

$$\pi_B^* \colon \mathrm{Cat}_T \rightleftarrows \mathrm{Cat}_{T/B} : (\pi_B)_* = (- \times B)^*.$$

Lemma 2.1.18. *Consider an object $B \in T$. Then there is for every ∞-category $\mathcal{E}$ an equivalence of $T_{/B}$-∞-categories*

$$\pi_B^* \underline{\mathcal{E}}_T \simeq \underline{\mathcal{E}}_{T_{/B}},$$

natural in $\mathcal{E}$.

Proof. It will suffice to prove that the composite

$$T_{/B} \xrightarrow{\pi_B} T \xrightarrow{A \mapsto (T_{/A})^{\mathrm{op}}} \mathrm{Cat}_\infty$$

is equivalent to the slice functor of $T_{/B}$. This is immediate from the observation that the target map $\mathrm{ev}_1 \colon (T_{/B})^{[1]} \to T_{/B}$ of $T_{/B}$ is the pullback along π_B of the target map $\mathrm{ev}_1 \colon T^{[1]} \to T$. □

2.2. **Parametrized functor categories.** In this subsection, we establish a variety of basic results on parametrized functor categories.

Definition 2.2.1. Since T is small and Cat_∞ is cartesian closed, the ∞-category $\mathrm{Cat}_T = \mathrm{Fun}(T^{\mathrm{op}}, \mathrm{Cat}_\infty)$ is again cartesian closed. Given two T-∞-categories $\mathcal{C}$ and $\mathcal{D}$, we define the *T-∞-category of T-functors* $\mathcal{C} \to \mathcal{D}$, denoted $\underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D})$, as the internal hom-object between $\mathcal{C}$ and $\mathcal{D}$ in the ∞-category Cat_T. In particular, for any triple of T-∞-categories $\mathcal{C}$, $\mathcal{D}$ and $\mathcal{E}$ there is a natural equivalence

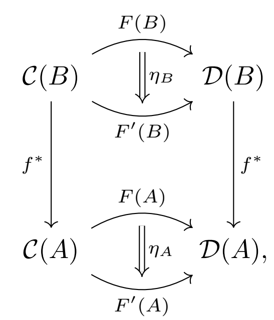
$$\underline{\mathrm{Fun}}_T(\mathcal{C} \times \mathcal{D}, \mathcal{E}) \simeq \underline{\mathrm{Fun}}_T(\mathcal{C}, \underline{\mathrm{Fun}}_T(\mathcal{D}, \mathcal{E})).$$

Definition 2.2.2. Given two T-∞-categories $\mathcal{C}$ and $\mathcal{D}$, we define the ∞-category $\mathrm{Fun}_T(\mathcal{C}, \mathcal{D})$ of T-functors $\mathcal{C} \to \mathcal{D}$ as the underlying ∞-category of the T-∞-category $\underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D})$:

$$\mathrm{Fun}_T(\mathcal{C}, \mathcal{D}) := \Gamma(\underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D})).$$

Remark 2.2.3. The objects of $\mathrm{Fun}_T(\mathcal{C}, \mathcal{D})$ may be identified with T-functors $\mathcal{C} \to \mathcal{D}$. If F and F' are two such T-functors, we refer to a morphism $\alpha \colon F \to F'$ in $\mathrm{Fun}_T(\mathcal{C}, \mathcal{D})$ as a *natural transformation of T-functors*. A natural transformation of

T-functors is given by a collection of natural transformations $\eta_A\colon F(A) \to F'(A)$ together with a coherent collection of 3-cells which fill the cylinders



for every morphism $f\colon A \to B$ in T.

Example 2.2.4. The T-functors of the form $\mathcal{C}^{\mathrm{op}} \to \underline{\mathrm{Spc}}_T$ are called *T-presheaves on $\mathcal{C}$*. There is an analogue of the Yoneda embedding,

$$y\colon\ \mathcal{C} \to \underline{\mathrm{Fun}}_T(\mathcal{C}^{\mathrm{op}}, \underline{\mathrm{Spc}}_T),$$

see [BDG$^+$16, Section 10] or [Mar21, Section 4.7], which is fully faithful by [Mar21, Theorem 4.7.8].

Natural transformations between ordinary categories induce natural transformations between their associated T-∞-categories of T-objects.

Construction 2.2.5. Given ∞-categories $\mathcal{E}$ and $\mathcal{E}'$, we will construct a functor

$$\mathrm{Fun}(\mathcal{E}, \mathcal{E}') \to \mathrm{Fun}_T(\underline{\mathcal{E}}_T, \underline{\mathcal{E}'}_T)$$

which on groupoid cores reduces to the functoriality of the construction $\mathcal{E} \mapsto \underline{\mathcal{E}}_T$ of Example 2.1.11. By adjunction we may equivalently specify a T-functor of the form

$$\mathrm{const}_{\mathrm{Fun}(\mathcal{E},\mathcal{E}')} \times \underline{\mathcal{E}}_T \to \underline{\mathcal{E}'}_T.$$

At level $B \in T$, we define this as the composition functor

$$\mathrm{Fun}(\mathcal{E}, \mathcal{E}') \times \mathrm{Fun}((T_{/B})^{\mathrm{op}}, \mathcal{E}) \to \mathrm{Fun}((T_{/B})^{\mathrm{op}}, \mathcal{E}').$$

By precomposing with the functors $T^{\mathrm{op}}_{/A} \to T^{\mathrm{op}}_{/B}$ this specifies a T-functor.

The following result of [MW21] relates the ∞-category of T-functors from Definition 2.2.2 to the identically named ∞-category of T-functors from [BDG$^+$16, p.3].

Proposition 2.2.6 ([MW21, Proposition 3.2.1])**.** *For any two T-∞-categories $\mathcal{C}$ and $\mathcal{D}$ there is a natural equivalence*

$$\mathrm{Fun}_T(\mathcal{C}, \mathcal{D}) \simeq \mathrm{Fun}^{\mathrm{cocart}}_{/T^{\mathrm{op}}}(\textstyle\int \mathcal{C}, \int \mathcal{D}),$$

where the right-hand side denotes the full subcategory of $\mathrm{Fun}_{/T^{\mathrm{op}}}(\int \mathcal{C}, \int \mathcal{D})$ *spanned by those functors $\int \mathcal{C} \to \int \mathcal{D}$ over T^{op} that preserve cocartesian edges.* □

To give a pointwise description of the parametrized functor category $\underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D})$, we need the following enhanced version of the Yoneda lemma.

Lemma 2.2.7 (Categorical Yoneda lemma)**.** *For every $B \in T$ and $\mathcal{C} \in \mathrm{Cat}_T$, evaluation at the identity $\mathrm{id}_B \in \mathrm{Hom}_T(B, B) = \underline{B}(B)$ induces a natural equivalence of ∞-categories*

$$\mathrm{Fun}_T(\underline{B}, \mathcal{C}) \xrightarrow{\sim} \mathcal{C}(B).$$

Proof. By the Yoneda lemma and Remark 2.1.10 there is a natural equivalence

$$\mathrm{Hom}_{\mathrm{Cat}_T}(\underline{B}, \mathcal{C}) \simeq \iota(\mathcal{C}(B))$$

between the ∞-groupoid of T-functors $\underline{B} \to \mathcal{C}$ and the groupoid core of the ∞-category $\mathcal{C}(B)$, so the statement holds on groupoid cores. To obtain the statement on the level of categories, we use that the ∞-category Cat_T is cotensored over Cat_∞: for every T-∞-category $\mathcal{C}$ and every ∞-category $\mathcal{E}$, the cotensor $\mathcal{C}^{\mathcal{E}}$ is given at $B \in T$ by $\mathcal{C}^{\mathcal{E}}(B) \simeq \mathrm{Fun}(\mathcal{E}, \mathcal{C}(B))$. It follows that for any ∞-category $\mathcal{E}$ we have natural equivalences

$$\begin{aligned}\mathrm{Hom}_{\mathrm{Cat}_\infty}(\mathcal{E}, \mathrm{Fun}_T(\underline{B}, \mathcal{C})) &\simeq \mathrm{Hom}_{\mathrm{Cat}_T}(\underline{B}, \mathcal{C}^{\mathcal{E}}) \simeq \iota(\mathcal{C}^{\mathcal{E}}(B)) \\ &\simeq \iota(\mathrm{Fun}(\mathcal{E}, \mathcal{C}(B)) = \mathrm{Hom}_{\mathrm{Cat}_\infty}(\mathcal{E}, \mathcal{C}(B)),\end{aligned}$$

and thus the claim follows from the Yoneda lemma. □

By limit-extending the previous equivalence to presheaves, we immediately obtain:

Corollary 2.2.8. *There is a unique natural equivalence $\mathrm{Fun}_T(\underline{X}, \mathcal{C}) \simeq \mathcal{C}(X)$ of functors $\mathrm{PSh}(T) \times \mathrm{Cat}_T \to \mathrm{Cat}$ that for representable presheaves recovers the equivalence from the previous lemma.* □

Corollary 2.2.9. *Let $X \in \mathrm{PSh}(T)$ and let $\mathcal{C}$ and $\mathcal{D}$ be T-∞-categories. Then there are natural equivalences of ∞-categories*

$$\underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D})(X) \simeq \mathrm{Fun}_T(\underline{X}, \underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D})) \simeq \mathrm{Fun}_T(\underline{X} \times \mathcal{C}, \mathcal{D}) \simeq \mathrm{Fun}_T(\mathcal{C}, \underline{\mathrm{Fun}}_T(\underline{X}, \mathcal{D})).$$

Proof. The first equivalence is Corollary 2.2.8, while the others are immediate. □

Our next goal is to give an alternative description of the functor T-∞-category $\underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D})$.

Construction 2.2.10. Let $B \in T$ and let $\mathcal{C}$ and $\mathcal{D}$ be T-∞-categories. We define a $T_{/B}$-functor

$$\pi_B^* \colon \pi_B^* \underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D}) \to \underline{\mathrm{Fun}}_{T_{/B}}(\pi_B^* \mathcal{C}, \pi_B^* \mathcal{D})$$

as adjoint to the composite

$$\pi_B^* \underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D}) \times \pi_B^* \mathcal{C} \simeq \pi_B^*(\underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D}) \times \mathcal{C}) \xrightarrow{\pi_B^*(\mathrm{ev})} \pi_B^* \mathcal{D}\,.$$

We obtain T-functors

$$\underline{\mathrm{Fun}}_T(\underline{B}, \mathcal{D}) \to (\pi_B)_* \pi_B^* \mathcal{D} \qquad \text{and} \qquad (\pi_B)_! \pi_B^* \mathcal{C} \to \underline{B} \times \mathcal{C}\,.$$

The first one is adjoint to the composite $T_{/B}$-functor

$$\pi_B^* \underline{\mathrm{Fun}}_T(\underline{B}, \mathcal{D}) \xrightarrow{\pi_B^*} \underline{\mathrm{Fun}}_{T_{/B}}(\pi_B^* \underline{B}, \pi_B^* \mathcal{D}) \xrightarrow{\mathrm{ev}_{\mathrm{id}_B}} \pi_B^* \mathcal{D},$$

while the second one is adjoint to the composite

$$\pi_B^* \mathcal{C} \xrightarrow{(\iota, \mathrm{id})} \pi_B^* \underline{B} \times \pi_B^* \mathcal{C} \simeq \pi_B^*(\underline{B} \times \mathcal{C}).$$

Here $\mathrm{ev}_{\mathrm{id}_B}$ denotes evaluation at the object $\mathrm{id}_B \in \Gamma(\pi_B^*\underline{B}) = \mathrm{Hom}_T(B,B)$, and ι picks out $\mathrm{id}_B \in \Gamma(\pi_B^*\underline{B}) = \mathrm{Hom}_T(B,B)$. Observe that the resulting map $(\pi_B)_!\pi_B^*\mathcal{C} \to \underline{B}\times\mathcal{C}$ is the total mate of the map $\underline{\mathrm{Fun}}_T(\underline{B},\mathcal{D}) \to (\pi_B)_*\pi_B^*\mathcal{D}$.

Corollary 2.2.11. *Let $\mathcal{C}$ and $\mathcal{D}$ be T-∞-categories and let $B \in T$. The following hold:*

(1) The T-functors

$$\underline{\mathrm{Fun}}_T(\underline{B},\mathcal{D}) \xrightarrow{\sim} (\pi_B)_*\pi_B^*\mathcal{D} \qquad \text{and} \qquad (\pi_B)_!\pi_B^*\mathcal{C} \xrightarrow{\sim} \underline{B}\times\mathcal{C}$$

from Construction 2.2.10 are equivalences of T-∞-categories.

(2) The $T_{/B}$-functor

$$\pi_B^*\colon \pi_B^*\underline{\mathrm{Fun}}_T(\mathcal{C},\mathcal{D}) \xrightarrow{\sim} \underline{\mathrm{Fun}}_{T_{/B}}(\pi_B^*\mathcal{C},\pi_B^*\mathcal{D})$$

from Construction 2.2.10 is an equivalence of $T_{/B}$-∞-categories.

(3) In particular, passing to global sections gives an equivalence of ∞-categories

$$\underline{\mathrm{Fun}}_T(\mathcal{C},\mathcal{D})(B) \xrightarrow{\sim} \mathrm{Fun}_{T_{/B}}(\pi_B^*\mathcal{C},\pi_B^*\mathcal{D}).$$

Proof. For part (1), it suffices to show the first equivalence, since the second equivalence follows by passing to total mates. For this, we have to show that for every object $A \in T$ the induced map $\underline{\mathrm{Fun}}_T(\underline{B},\mathcal{D})(A) \to (\pi_B)_*\pi_B^*\mathcal{D}(A) = \mathcal{D}(A\times B)$ is an equivalence. Given Lemma 2.2.7, it will suffice to show that the following diagram commutes:

$$\begin{array}{ccc}
\mathrm{Fun}_T(\underline{A},\underline{\mathrm{Fun}}_T(\underline{B},\mathcal{D})) & \xrightarrow{\sim} & \mathrm{Fun}_T(\underline{A\times B},\mathcal{D}) \\
{\scriptstyle 2.2.7}\downarrow{\scriptstyle\sim} & & {\scriptstyle 2.2.7}\downarrow{\scriptstyle\sim} \\
\underline{\mathrm{Fun}}_T(\underline{B},\mathcal{D})(A) & \longrightarrow & \mathcal{D}(A\times B).
\end{array}$$

This follows from unwinding the definitions, using the observation that the equivalence $\mathrm{Fun}_T(\underline{B},\mathcal{D}) \to \mathcal{D}(B)$ from Lemma 2.2.7 is the map induced on global sections by the map $\underline{\mathrm{Fun}}_T(\underline{B},\mathcal{D}) \to (\pi_B)_*\pi_B^*\mathcal{D}$.

We will next prove part (3). It suffices to show that the following diagram commutes:

$$\begin{array}{ccccc}
\mathrm{Fun}_T(\underline{B},\underline{\mathrm{Fun}}_T(\mathcal{C},\mathcal{D})) & \xrightarrow{\sim} & \mathrm{Fun}_T(\mathcal{C},\underline{\mathrm{Fun}}_T(\underline{B},\mathcal{D})) & \xrightarrow[(1)]{\sim} & \mathrm{Fun}_T(\mathcal{C},(\pi_B)_*\pi_B^*\mathcal{D}) \\
{\scriptstyle 2.2.7}\downarrow{\scriptstyle\sim} & & & & \downarrow{\scriptstyle\sim} \\
\underline{\mathrm{Fun}}_T(\mathcal{C},\mathcal{D})(B) & & \xrightarrow{\pi_B^*(B)} & & \mathrm{Fun}_{T_{/B}}(\pi_B^*\mathcal{C},\pi_B^*\mathcal{D}).
\end{array}$$

This is again a matter of unwinding definitions, using that the equivalence of (1) is defined in terms of the map π_B^* and evaluation at id_B.

Finally, for part (2) it remains to show that the map π_B^* induces an equivalence when evaluated at every object $A \in T_{/B}$. To see this, consider the following two $T_{/A}$-functors:

$$\pi_A^*\underline{\mathrm{Fun}}_T(\mathcal{C},\mathcal{D}) \to \pi_A^*\underline{\mathrm{Fun}}_{T_{/B}}(\pi_B^*\mathcal{C},\pi_B^*\mathcal{D}) \to \underline{\mathrm{Fun}}_{T_{/A}}(\pi_A^*\mathcal{C},\pi_A^*\mathcal{D}).$$

Here we abuse notation by writing A both for an object in $T_{/B}$ and for its underlying object in T. By part (3), both the second map and the composite map induce equivalences on global sections, and therefore so does the first. This finishes the proof. $\square$

For later use let us describe the functoriality of $\underline{\mathrm{Fun}}_T(\pi_B^*\mathcal{C}, \pi_B^*\mathcal{D})$ in B. While this can be done in a fully coherent fashion using the results and techniques of [HHLN22a], for the purposes of the present paper the following more elementary lemma will be sufficient:

Lemma 2.2.12. *Let $f\colon A \to B$ be a map in T, and let $\sigma\colon \pi_B \circ T_{/f} \simeq \pi_A$ be the usual equivalence. Then the diagram*

$$\begin{array}{ccccc}
\mathrm{Hom}_{T_{/B}}(\pi_B^*\mathcal{C}, \pi_B^*\mathcal{D}) & \xrightarrow{T_{/f}^*} & \mathrm{Hom}_{T_{/A}}(T_{/f}^*\pi_B^*\mathcal{C}, T_{/f}^*\pi_B^*\mathcal{D}) & \xrightarrow{\sigma^*} & \mathrm{Hom}_{T_{/A}}(\pi_A^*\mathcal{C}, \pi_A^*\mathcal{D}) \\
\big\downarrow & & & & \big\downarrow \\
\mathrm{Fun}_{T_{/B}}(\pi_B^*\mathcal{C}, \pi_B^*\mathcal{D}) & & & & \mathrm{Fun}_{T_{/A}}(\pi_A^*\mathcal{C}, \pi_A^*\mathcal{D}) \\
\sim\big\downarrow 2.2.11 & & & & \sim\big\downarrow 2.2.11 \\
\underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D})(B) & & \xrightarrow[f^*]{\hspace{6em}} & & \underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D})(A)
\end{array}$$

of natural transformations of functors $\mathrm{Cat}_T^{\mathrm{op}} \times \mathrm{Cat}_T \to \mathrm{Cat}_\infty$ commutes up to homotopy.

Proof. Unravelling the definitions and using the naturality of the equivalences from the previous corollary, it suffices to construct a homotopy filling

$$\begin{array}{ccccc}
\mathrm{Hom}_{T_{/B}}(\pi_B^*\mathcal{C}, \pi_B^*\mathcal{D}) & \xrightarrow{T_{/f}^*} & \mathrm{Hom}_{T_{/A}}(T_{/f}^*\pi_B^*\mathcal{C}, T_{/f}^*\pi_B^*\mathcal{D}) & \xrightarrow{\sigma^*} & \mathrm{Hom}_{T_{/A}}(\pi_A^*\mathcal{C}, \pi_A^*\mathcal{D}) \\
\sim\big\downarrow & & & & \big\downarrow\sim \\
\mathrm{Hom}_T(\pi_{B!}\pi_B^*\mathcal{C}, \mathcal{D}) & & & & \mathrm{Hom}_T(\pi_{A!}\pi_A^*\mathcal{C}, \mathcal{D}) \\
j_B^*\big\downarrow & & & & \big\downarrow j_A^* \\
\mathrm{Hom}_T(\underline{B} \times \mathcal{C}, \mathcal{D}) & & \xrightarrow[(f\times\mathcal{C})^*]{\hspace{6em}} & & \mathrm{Hom}_T(\underline{A} \times \mathcal{C}, \mathcal{D})
\end{array}$$

where the unlabelled equivalences come from adjunction and $j_A\colon \pi_{A!}\pi_A^*\mathcal{C} \to \underline{A} \times \mathcal{C}$, $j_B\colon \pi_{B!}\pi_B^*\mathcal{C} \to \underline{B} \times \mathcal{C}$ are as in Corollary 2.2.11 again.

Obviously, we can make the lower half commute by adding the restriction along the composite $\pi_{A!}\pi_A^*\mathcal{C} \simeq \underline{A} \times \mathcal{C} \to \underline{B} \times \mathcal{C} \simeq \pi_{B!}\pi_B^*$ as the middle arrow. Similarly, we can make the upper portion commute by taking the restriction along

$$f_\Diamond\colon (\pi_A)_!\pi_A^*\mathcal{C} \xrightarrow[\sim]{\sigma^*} (\pi_A)_!T_{/f}^*\pi_B^*\mathcal{C} \longrightarrow (\pi_B)_!\pi_B^*\mathcal{C}$$

instead, where the second map is the mate of σ^*. It will therefore suffice to show that these two natural transformations $\pi_{A!}\pi_A^* \Rightarrow \pi_{B!}\pi_B^*$ are in fact homotopic. Plugging in the definitions of the equivalences j_A and j_B, this amounts to saying that $j_B f_\Diamond$ is adjunct to the map $\pi_A^*\mathcal{C} \to \pi_A^*\underline{B} \times \pi_A^*\mathcal{C}$ picking out $f \in (\pi_A^*\underline{B})(\mathrm{id}_A) = \mathrm{Hom}(A, B)$.

Further plugging in definitions, the adjunct of $jf_\Diamond$ is the top right composite in

$$\begin{array}{ccccccc}
\pi_A^*\mathcal{C} & \xrightarrow{\sigma^*} & T_{/f}^*\pi_B^*\mathcal{C} & \xrightarrow{\eta} & T_{/f}^*\pi_B^*(\pi_B)_!\pi_B^*\mathcal{C} & \xrightarrow{(\sigma^{-1})^*} & \pi_A^*(\pi_B)_!\pi_B^*\mathcal{C} \\
& & & \searrow & j_B\big\downarrow & & \big\downarrow j_B \\
& & & & T_{/f}^*\pi_B^*(\underline{B} \times \mathcal{C}) & \xrightarrow[(\sigma^{-1})^*]{} & \pi_A^*(\underline{B} \times \mathcal{C}).
\end{array}$$

The square on the right commutes by naturality and the dashed composite is by definition the adjunct of j_B, i.e. it is induced by the map $\pi_B^*\mathcal{C} \to \pi_B^*(\underline{B} \times \mathcal{C})$ classifying $\mathrm{id}_B \in \underline{B}(B)$. It follows that after postcomposing with the projection $\pi_A^*(\underline{B} \times \mathcal{C}) \to \pi_A^*\mathcal{C}$ the above is simply the identity, and it remains to show that the natural map $\pi_A^*\mathcal{C} \to \pi_A^*\underline{B}$ obtained by postcomposing with the other projection classifies $f \in \underline{B}(A)$. But indeed, as a functor of Cat_T the right hand side is constant, so any natural transformation into it is determined by its value on the terminal object. Together with application of the Yoneda lemma it therefore suffices that for $\mathcal{C} = *$ the map $(\pi_A^* *)(\mathrm{id}_A) \to (\pi_A^*\underline{B})(\mathrm{id}_A)$ hits f. However, by the above commutative diagram this can be identified with $(\pi_B^* *)(f) \to (\pi_B^*\underline{B})(f)$, which hits $f = f^*(\mathrm{id}_B)$ for formal reasons. □

We will now prove the adjunction between $\mathcal{E} \mapsto \underline{\mathcal{E}}_T$ and $\mathcal{C} \mapsto \int\mathcal{C}$ promised in Remark 2.1.12.

Lemma 2.2.13. *The functor $\int\colon \mathrm{Cat}_T \to \mathrm{Cat}_\infty$, sending a T-∞-category $\mathcal{C}\colon T^{\mathrm{op}} \to \mathrm{Cat}_\infty$ to the total space $\int\mathcal{C}$ of the cocartesian fibration $\int\mathcal{C} \to T^{\mathrm{op}}$ it classifies, admits a right adjoint given by the construction $\mathcal{E} \mapsto \underline{\mathcal{E}}_T$ of Example 2.1.11.*

Proof. The functor $\int\colon \mathrm{Cat}_T \to \mathrm{Cat}_\infty$ can be expanded into the following composite functor:

$$\mathrm{Cat}_T \overset{2.1.4}{\simeq} (\mathrm{Cat}_\infty)^{\mathrm{cocart}}_{/T^{\mathrm{op}}} \hookrightarrow (\mathrm{Cat}_\infty)_{/T^{\mathrm{op}}} \xrightarrow{\mathrm{fgt}} \mathrm{Cat}_\infty$$

By [Lur17, Example B.2.10, Remark B.0.28], the functor in the middle is the underlying functor of a left Quillen functor between model categories, so that it admits a right adjoint by [Hin16, Proposition 1.5.1]. The second functor clearly admits a right adjoint. It follows that $\int\colon \mathrm{Cat}_T \to \mathrm{Cat}_\infty$ admits a right adjoint $R\colon \mathrm{Cat}_\infty \to \mathrm{Cat}_T$.

As a formal consequence we obtain for each T-∞-category $\mathcal{C}$ and for each ∞-category $\mathcal{E}$ a natural equivalence

$$\mathrm{Fun}_T(\mathcal{C}, R(\mathcal{E})) \simeq \mathrm{Fun}(\textstyle\int\mathcal{C}, \mathcal{E})$$

between the ∞-category T-functors $\mathcal{C} \to R(\mathcal{E})$ and the ∞-category of functors $\int\mathcal{C} \to \mathcal{E}$: for every other ∞-category $\mathcal{E}'$ there is a natural equivalence

$$\begin{aligned}\mathrm{Hom}_{\mathrm{Cat}_T}(\mathcal{E}', \mathrm{Fun}_T(\mathcal{C}, R(\mathcal{E}))) &\simeq \mathrm{Hom}_{\mathrm{Cat}_T}(\mathcal{C} \times \mathrm{const}_{\mathcal{E}'}, R(\mathcal{E})) \\ &\simeq \mathrm{Hom}_{\mathrm{Cat}_\infty}(\textstyle\int(\mathcal{C} \times \mathrm{const}_{\mathcal{E}'}), \mathcal{E}) \\ &\simeq \mathrm{Hom}_{\mathrm{Cat}_\infty}(\textstyle\int\mathcal{C} \times \mathcal{E}', \mathcal{E}) \\ &\simeq \mathrm{Hom}_{\mathrm{Cat}_\infty}(\mathcal{E}', \mathrm{Fun}(\textstyle\int\mathcal{C}, \mathcal{E})),\end{aligned}$$

where we use that the cocartesian unstraightening of $\mathrm{const}_{\mathcal{E}'}$ is $T^{\mathrm{op}} \times \mathcal{E}'$ and that the inclusion $(\mathrm{Cat}_\infty)^{\mathrm{cocart}}_{/T^{\mathrm{op}}} \hookrightarrow (\mathrm{Cat}_\infty)_{/T^{\mathrm{op}}}$ preserves finite products. The claim now follows from the Yoneda lemma.

The description of R as the functor $\mathcal{E} \mapsto \underline{\mathcal{E}}_T$ from Example 2.1.11 now follows immediately by recalling that the cocartesian unstraightening of the functor $\underline{B} = \mathrm{Hom}_T(-, B)\colon T^{\mathrm{op}} \to \mathrm{Spc}$ is by definition given by the target functor $(T_{/B})^{\mathrm{op}} \to T^{\mathrm{op}}$. Namely for any $\mathcal{E} \in \mathrm{Cat}_\infty$ and $B \in T$ we have a natural equivalence

$$R(\mathcal{E})(B) \overset{2.2.7}{\simeq} \mathrm{Fun}_T(\underline{B}, R(\mathcal{E})) \simeq \mathrm{Fun}(\textstyle\int\underline{B}, \mathcal{E}) \simeq \mathrm{Fun}((T_{/B})^{\mathrm{op}}, \mathcal{E}) = \underline{\mathcal{E}}_T(B). \quad (1)$$

This finishes the proof. □

Remark 2.2.14. Combining the previous lemma and Corollary 2.2.9 we obtain a natural equivalence

$$\underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{E}_T) \simeq \mathrm{Fun}(\textstyle\int \mathcal{C} \times \underline{(-)}, \mathcal{E}).$$

Remark 2.2.15. Let $B \in T$ arbitrary. Unravelling the chain of equivalences (1) we see that the diagram

$$\begin{array}{ccc} \mathrm{Fun}_T(\underline{B}, \underline{\mathcal{E}}_T) & \xrightarrow{\text{adjunction}} & \mathrm{Fun}(\int \underline{B}, \mathcal{E}) \\ {\scriptstyle\text{Yoneda}}\big\downarrow & & \big\downarrow{\scriptstyle f^*} \\ \underline{\mathcal{E}}_T(B) & = & \mathrm{Fun}(T_{/B}, \mathcal{E}) \end{array}$$

of equivalences commutes up to natural equivalence where f is the chosen identification of $\int \underline{B}$ with $T_{/B}$ over T.

Now assume T has a final object 1. Specializing the above to $B = 1$ (and identifying $T_{/1}$ with T as usual), we see that

$$\begin{array}{ccc} \mathrm{Fun}_T(\underline{1}, \underline{\mathcal{E}}_T) & \underset{\simeq}{\xrightarrow{\text{adjunction}}} & \mathrm{Fun}(\int \underline{1}, \mathcal{E}) \\ {\scriptstyle\text{Yoneda}}\big\downarrow{\scriptstyle\simeq} & & \big\uparrow{\scriptstyle \pi^*} \\ \mathcal{E}_T(1) & = & \mathrm{Fun}(T^{\mathrm{op}}, \mathcal{E}) \end{array}$$

commutes up to natural equivalence, where $\pi\colon \int \underline{1} \to T^{\mathrm{op}}$ is the cocartesian projection. Combining this with the naturality of the adjunction equivalence, we conclude that we have for every T-∞-category $\mathcal{C}$ and $c \in \mathcal{C}(1)$ a natural equivalence filling

$$\begin{array}{ccc} \mathrm{Fun}_T(\mathcal{C}, \underline{\mathcal{E}}_T) & \underset{\simeq}{\xrightarrow{\text{adjunction}}} & \mathrm{Fun}(\int \mathcal{C}, \mathcal{E}) \\ {\scriptstyle\mathrm{ev}_c}\big\downarrow & & \big\downarrow{\scriptstyle \hat{c}^*} \\ \underline{\mathcal{E}}_T(1) & = & \mathrm{Fun}(T^{\mathrm{op}}, \mathcal{E}) \end{array}$$

where $\hat{c}\colon T^{\mathrm{op}} \to \int \mathcal{C}$ is the essentially unique map over T^{op} sending the fiber over $1 \in T$ to c (i.e. the unstraightening of c viewed as a T-functor $\underline{1} \to \mathcal{C}$).

Remark 2.2.16. We can make the equivalence $\mathrm{Fun}_T(\mathcal{C}, \underline{\mathcal{E}}_T) \simeq \mathrm{Fun}(\int \mathcal{C}, \mathcal{E})$ of Lemma 2.2.13 more explicit. Consider a functor $\tilde{F}\colon \int \mathcal{C} \to \mathcal{E}$. The associated T-functor $F\colon \mathcal{C} \to \underline{\mathcal{E}}_T$ is given at $B \in T$ by the functor

$$F_B\colon \mathcal{C}(B) \to \mathrm{Fun}(T^{\mathrm{op}}_{/B}, \mathcal{E}),$$

where $F_B(X)(h\colon C \to B) = \tilde{F}(h^*(X))$, the value of $\tilde{F}$ on the cocartesian pushforward of $X \in \mathcal{C}(B)$ along h to $\mathcal{C}(C)$. The value of $F_B(X)$ on a triangle

$$\begin{array}{ccc} C & \xrightarrow{f} & D \\ & {\scriptstyle h}\searrow \quad \swarrow{\scriptstyle g} & \\ & B & \end{array}$$

is given by applying $\tilde{F}$ to the cocartesian edge over f from $g^*(X)$ to $h^*(X)$. More generally, for another object $B' \in T$ and a functor $\tilde{F}\colon \int(\mathcal{C} \times \underline{B'}) \to \mathcal{E}$, the associated

T-functor $F\colon \mathcal{C} \to \underline{\mathrm{Fun}}(\underline{B}, \mathcal{E})$ is given at $B \in T$ by the functor $F_B\colon \mathcal{C}(B) \to \mathrm{Fun}(T^{\mathrm{op}}_{/B\times B'}, \mathcal{E})$ given by

$$F_B(X)(A \xrightarrow{(f_B, f_{B'})} B \times B') = \tilde{F}(A, f_B^* X, f_{B'}).$$

2.3. **Parametrized adjunctions, limits and colimits.** We will briefly recall the parametrized versions of adjunctions, limits and colimits, following Sections 3 and 4 of [MW21] (see Remark 2.1.14). An alternative treatment in the language of cocartesian fibrations over T^{op} is given by [Sha21, Sections 8 and 9].

Definition 2.3.1 ([MW21, Definition 3.1.1])**.** Let $\mathcal{C}$ and $\mathcal{D}$ be T-∞-categories. An *adjunction* between $\mathcal{C}$ and $\mathcal{D}$ is a tuple $(L, R, \eta, \varepsilon)$, where $L\colon \mathcal{C} \to \mathcal{D}$ and $R\colon \mathcal{D} \to \mathcal{C}$ are T-functors and where $\eta\colon \mathrm{id}_{\mathcal{D}} \to RL$ and $\varepsilon\colon LR \to \mathrm{id}_{\mathcal{C}}$ are natural transformations of T-functors fitting in commutative triangles

$$\begin{array}{ccc} L & \xrightarrow{L\eta} & LRL \\ & \searrow & \downarrow{\scriptstyle \varepsilon L} \\ & & L \end{array} \qquad \text{and} \qquad \begin{array}{ccc} RLR & \xleftarrow{\eta R} & R \\ {\scriptstyle R\varepsilon}\downarrow & \swarrow & \\ R. & & \end{array}$$

Note that the notion of an adjunction between two T-∞-categories only depends on the (homotopy) 2-category associated to Cat_T and in particular many of the standard 2-categorical results about adjunctions hold in this setting.

Example 2.3.2. Every adjunction $\mathcal{E} \rightleftarrows \mathcal{E}'$ of ∞-categories gives rise to an adjunction $\mathrm{const}_{\mathcal{E}} \rightleftarrows \mathrm{const}_{\mathcal{E}'}$ on associated constant T-∞-categories.

Example 2.3.3. By Construction 2.2.5, every adjunction $\mathcal{E} \rightleftarrows \mathcal{E}'$ of ∞-categories gives rise to an adjunction $\underline{\mathcal{E}}_T \rightleftarrows \underline{\mathcal{E}'}_T$ on associated T-∞-categories of T-objects.

Important will be the following 'pointwise' criterion for checking that a T-functor has a parametrized adjoint.

Proposition 2.3.4 ([MW21, Proposition 3.2.8 and Corollary 3.2.10])**.** *A T-functor $F\colon \mathcal{C} \to \mathcal{D}$ admits a (parametrized) right adjoint if and only if the following two conditions hold:*

(1) For every object $B \in T$, the induced functor $F(B)\colon \mathcal{C}(B) \to \mathcal{D}(B)$ admits a right adjoint $G(B)\colon \mathcal{D}(B) \to \mathcal{C}(B)$;
(2) For every morphism $f\colon A \to B$ in T, the Beck-Chevalley transformation

$$f^* \circ G(B) \implies G(A) \circ f^*$$

given as the mate of the naturality square

$$\begin{array}{ccc} \mathcal{C}(B) & \xrightarrow{F(B)} & \mathcal{D}(A) \\ {\scriptstyle f^*}\downarrow & & \downarrow{\scriptstyle f^*} \\ \mathcal{C}(A) & \xrightarrow{F(A)} & \mathcal{D}(A) \end{array}$$

is an equivalence.

If this is the case, the right adjoint $G\colon \mathcal{D} \to \mathcal{C}$ of F is given on an object $B \in T$ by the functor $G(B)\colon \mathcal{D}(B) \to \mathcal{C}(B)$. Moreover, if $Y \in \mathrm{PSh}(T)$ is any presheaf, then also the functor $F(Y)\colon \mathcal{C}(Y) \to \mathcal{D}(Y)$ admits a right adjoint $G(Y)$ in this case, and *for any map* $f\colon X \to Y$ *in* $\mathrm{PSh}(T)$ *the Beck-Chevalley map* $f^* \circ G(Y) \Rightarrow G(X) \circ f^*$ *is an equivalence.*

The dual statement for parametrized left adjoints also holds. □

We will now move to parametrized limits and colimits, of which we will only give a brief treatment sufficient for the purposes of the present article.

Definition 2.3.5. Let K and $\mathcal{C}$ be T-∞-categories. We say that $\mathcal{C}$ *admits* K-*indexed colimits* if the diagonal functor $\mathrm{diag}\colon \mathcal{C} \to \underline{\mathrm{Fun}}_T(K, \mathcal{C})$ given by precomposing with $K \to \underline{1}$ admits a left adjoint $\mathrm{colim}_K \colon \underline{\mathrm{Fun}}_T(K, \mathcal{C}) \to \mathcal{C}$. Similarly we say that $\mathcal{C}$ *admits* K*-indexed limits* if diag admits a right adjoint $\lim_K \colon \underline{\mathrm{Fun}}_T(K, \mathcal{C}) \to \mathcal{C}$.

Definition 2.3.6. Let K, $\mathcal{C}$ and $\mathcal{D}$ be T-∞-categories and assume that $\mathcal{C}$ and $\mathcal{D}$ admit K-indexed colimits. We will say that a T-functor $F\colon \mathcal{C} \to \mathcal{D}$ *preserves* K-*indexed colimits* if the Beck-Chevalley transformation $\mathrm{colim}_K \circ \underline{\mathrm{Fun}}_T(K, F) \implies F \circ \mathrm{colim}_K$ of the naturality square

$$\begin{array}{ccc} \mathcal{C} & \xrightarrow{\mathrm{diag}} & \underline{\mathrm{Fun}}_T(K, \mathcal{C}) \\ {\scriptstyle F}\downarrow & & \downarrow{\scriptstyle \underline{\mathrm{Fun}}_T(K,F)} \\ \mathcal{D} & \xrightarrow{\mathrm{diag}} & \underline{\mathrm{Fun}}_T(K, \mathcal{D}) \end{array}$$

is an equivalence.

In the non-parametrized context, one often asks an ∞-category to admit (co)limits for a certain class of indexing diagrams. In the parametrized setting, one should work with the following parametrized notion of 'class of indexing diagrams'.

Definition 2.3.7. Let T be an ∞-category. A *class of* T-∞-*categories* is a full parametrized subcategory $\mathbf{U} \subseteq \underline{\mathrm{cat}}_T$ of the T-∞-category of small T-∞-categories.

Definition 2.3.8 ([MW21, Definition 5.2.1 and Remark 5.2.4])**.** Let $\mathbf{U}$ be a class of T-∞-categories and let $\mathcal{C}$ and $\mathcal{D}$ be T-∞-categories.

(1) We will say that $\mathcal{C}$ *admits* $\mathbf{U}$-*colimits* if the $T_{/B}$-∞-category $\pi_B^* \mathcal{C}$ of Example 2.1.17 admits K-indexed $T_{/B}$-colimits for every $B \in T$ and $K \in \mathbf{U}(B) \subseteq \mathrm{Cat}(T_{/B})$.
(2) If $\mathcal{C}$ and $\mathcal{D}$ admit $\mathbf{U}$-colimits, a T-functor $F\colon \mathcal{C} \to \mathcal{D}$ is said to *preserve* $\mathbf{U}$-*colimits* if $\pi_B^* F$ preserves K-indexed $T_{/B}$-colimits for every $B \in T$ and $K \in \mathbf{U}(B)$.

Dually, $\mathcal{C}$ is said to *admit* $\mathbf{U}$-*limits* if for every $B \in T$ and $K \in \mathbf{U}(B)$, the $T_{/B}$-∞-category $\pi_B^* \mathcal{C}$ admits K-indexed $T_{/B}$-limits. A T-functor $F\colon \mathcal{C} \to \mathcal{D}$ is said to *preserve* $\mathbf{U}$-*limits* if $\pi_B^* F$ preserved K-indexed $T_{/B}$-limits for every $B \in T$ and $K \in \mathbf{U}(B)$.

If $\mathbf{U} = \underline{\mathrm{cat}}_T$ consists of *all* T-∞-categories, we will say that $\mathcal{C}$ is T-*cocomplete* or T-*complete* respectively.

From the pointwise criterion Proposition 2.3.4 of parametrized adjunctions, we immediately obtain characterizations of T-(co)limits indexed by constant T-∞-categories and T-∞-groupoids, respectively. We start with the case of constant T-∞-categories.

Lemma 2.3.9 (cf. [MW21, Example 4.1.10 and Remark 4.1.11])**.** *Let $\mathcal{C}$ be a T-∞-category, let K be an ∞-category, and let const_K be the associated constant T-∞-category. Then the following conditions are equivalent:*

(1) The T-∞-category $\mathcal{C}$ admits const_K-indexed colimits;
(2) For every object $B \in T$ the ∞-category $\mathcal{C}(B)$ admits K-indexed colimits, and for every morphism $\beta\colon B' \to B$ in T the restriction functor $\beta^*\colon \mathcal{C}(B) \to \mathcal{C}(B')$ preserves K-indexed colimits.
(3) For every presheaf $Y \in \mathrm{PSh}(T)$, the ∞-category $\mathcal{C}(Y)$ admits K-indexed colimits, and for every morphism $\beta\colon Y' \to Y$ in $\mathrm{PSh}(T)$ the restriction $\beta^*\colon \mathcal{C}(Y) \to \mathcal{C}(Y')$ preserves K-indexed colimits.

The dual statement for limits also holds.

Proof. We apply the natural identification

$$\begin{aligned}\underline{\mathrm{Fun}}_T(\mathrm{const}_K, \mathcal{C})(B) &\overset{2.2.9}{\simeq} \mathrm{Fun}_T(\mathrm{const}_K, \underline{\mathrm{Fun}}_T(\underline{B}, \mathcal{C}))\\ &\overset{2.1.8}{\simeq} \mathrm{Fun}(K, \mathrm{Fun}_T(\underline{B}, \mathcal{C}))\\ &\overset{2.2.7}{\simeq} \mathrm{Fun}(K, \mathcal{C}(B)).\end{aligned}$$

Because each equivalence above is natural in K, we find that under this identification the T-functor $\mathrm{diag}\colon \mathcal{C} \to \underline{\mathrm{Fun}}_T(K, \mathcal{C})$ corresponds at $B \in T$ to the standard diagonal functor. Furthermore the Beck-Chevalley transformation associated to the naturality square

$$\begin{array}{ccc}\mathcal{C}(B) & \xrightarrow{\mathrm{diag}} & \mathrm{Fun}(K, \mathcal{C}(B))\\ {\scriptstyle \beta^*}\downarrow & & \downarrow{\scriptstyle \mathrm{Fun}(K,\beta^*)}\\ \mathcal{C}(B') & \xrightarrow{\mathrm{diag}} & \mathrm{Fun}(K, \mathcal{C}(B'))\end{array}$$

is the standard comparison $\mathrm{colim} \circ \mathrm{Fun}(K, \beta^*) \Rightarrow F \circ \mathrm{colim}_K$. Therefore the equivalence of the first two statements is an instance of Proposition 2.3.4.

The equivalence between the first and the third statement is proven in exactly the same way. □

The following result is proved similarly and will be left to the reader.

Lemma 2.3.10. *Let K be an ∞-category and let $\mathcal{C}$ and $\mathcal{D}$ be two T-∞-categories that admit const_K-indexed T-colimits. Then a T-functor $F\colon \mathcal{C} \to \mathcal{D}$ preserves const_K-indexed T-colimits if and only if for each $B \in T$ the functor $F(B)\colon \mathcal{C}(B) \to \mathcal{D}(B)$ preserves K-indexed colimits. Moreover, in this case $F(Y)\colon \mathcal{C}(Y) \to \mathcal{D}(Y)$ preserves K-indexed colimits for all $Y \in \mathrm{PSh}(T)$.*

The dual statement for limits also holds. □

Definition 2.3.11. If the equivalent conditions of Lemma 2.3.9 are satisfied, we say that $\mathcal{C}$ *admits fiberwise K-indexed colimits.* If S is a collection of small ∞-categories such that $\mathcal{C}$ admits fiberwise K-indexed colimits for every $K \in S$, we say that $\mathcal{C}$ *admits fiberwise S-indexed colimits*. We say that $\mathcal{C}$ is *fiberwise cocomplete* if $\mathcal{C}$ admits fiberwise K-indexed colimits for every small ∞-category K.

Dually one defines when $\mathcal{C}$ *admits fiberwise K-indexed limits* or is *fiberwise complete.*

We next describe parametrized colimits indexed by T-∞-groupoids.

Definition 2.3.12. A *class of T-∞-groupoids*[2] is a full parametrized subcategory $\mathbf{U} \subseteq \underline{\mathrm{Spc}}_T$ of the T-∞-category of T-∞-groupoids. A morphism $f\colon X \to Y$ in $\mathrm{PSh}(T)$ is said to be in $\mathbf{U}$ if it is an object in the full subcategory $\mathbf{U}(Y) \subseteq \mathrm{PSh}(T)_{/Y}$.

Remark 2.3.13. In the above definition, we have again viewed $\mathbf{U}$ as a sheaf on $\mathrm{PSh}(T)$ via limit extension. For later use, let us make explicit what this means in terms of the original functor $T^{\mathrm{op}} \to \mathrm{Cat}_\infty$: a map $f\colon X \to Y$ in $\mathrm{PSh}(T)$ belongs to $\mathbf{U}$ if and only if for every map $\beta\colon B \to Y$ from a representable presheaf $B \in T$ the pulled back map $\beta^* f\colon \beta^* X \to B$ is an object of $\mathbf{U}(B)$.

Lemma 2.3.14 (cf. [MW21, Example 4.1.9], [Sha21, Proposition 5.12])**.** *Let $\mathbf{U}$ be a class of T-∞-groupoids. Then a T-∞-category $\mathcal{C}$ admits $\mathbf{U}$-colimits if and only if for every morphism $p\colon A \to B$ in $\mathbf{U}$, with $B \in T$, the restriction functor $p^*\colon \mathcal{C}(B) \to \mathcal{C}(A)$ admits a left adjoint $p_!\colon \mathcal{C}(A) \to \mathcal{C}(B)$, and for every pullback square*

$$\begin{array}{ccc} A' & \xrightarrow{\alpha} & A \\ {\scriptstyle p'}\downarrow & \lrcorner & \downarrow{\scriptstyle p} \\ B' & \xrightarrow{\beta} & B \end{array} \tag{2}$$

in $\mathrm{PSh}(T)$ with $\beta\colon B' \to B$ in T and $p\colon A \to B$ in $\mathbf{U}$, the Beck-Chevalley transformation $p'_! \circ \alpha^* \Rightarrow \beta^* \circ p_!$ associated to the commutative diagram

$$\begin{array}{ccc} \mathcal{C}(B) & \xrightarrow{\beta^*} & \mathcal{C}(B') \\ {\scriptstyle p^*}\downarrow & & \downarrow{\scriptstyle p'^*} \\ \mathcal{C}(A) & \xrightarrow{\alpha^*} & \mathcal{C}(A') \end{array}$$

is a natural equivalence.

Dually, $\mathcal{C}$ admits $\mathbf{U}$-limits if and only if $p^*\colon \mathcal{C}(B) \to \mathcal{C}(A)$ admits a right adjoint $p_*\colon \mathcal{C}(A) \to \mathcal{C}(B)$ for every morphism $p\colon A \to B$ in $\mathbf{U}$ and for every pullback square (2), the Beck-Chevalley transformation $\beta^* \circ p_* \Rightarrow p'_* \circ \alpha^*$ is a natural equivalence.

Proof. Let $(p\colon A \to B) \in \mathbf{U}(B) \subseteq \mathrm{PSh}(T)_{/B}$ be a morphism in $\mathbf{U}$. It suffices to show that the $T_{/B}$-∞-category $\pi_B^* \mathcal{C}$ admits $\underline{A}$-indexed colimits if and only if for every pullback diagram

$$\begin{array}{ccccc} A'' & \xrightarrow{\alpha'} & A' & \xrightarrow{\alpha} & A \\ {\scriptstyle p''}\downarrow & \lrcorner & {\scriptstyle p'}\downarrow & \lrcorner & \downarrow{\scriptstyle p} \\ B'' & \xrightarrow{\beta'} & B' & \xrightarrow{\beta} & B \end{array}$$

the functors p'^* and p''^* admit left adjoints $p'_!$ and $p''_!$, and the Beck-Chevalley transformation $p''_! \circ \alpha'^* \Rightarrow \beta'^* \circ p'_!$ is a natural equivalence. By replacing T by $T_{/B}$, we may assume $B = 1$ is a terminal object of T. Using the natural identifications

$$\underline{\mathrm{Fun}}_T(\underline{A}, \mathcal{C})(B') \overset{2.2.9}{\simeq} \mathrm{Fun}_T(\underline{A} \times \underline{B'}, \mathcal{C})) \simeq \mathrm{Fun}_T(\underline{A \times B'}, \mathcal{C})) \overset{2.2.7}{\simeq} \mathcal{C}(A \times B'),$$

this is an instance of Proposition 2.3.4 applied to the T-∞-category $\underline{\mathrm{Fun}}_T(\underline{A}, \mathcal{C})$. □

[2] This is called a 'subuniverse' in [Mar21, Definition 3.9.13]

Remark 2.3.15. If $\mathcal{C}$ is $\mathbf{U}$-cocomplete, then [MW21, Remark 5.2.4] shows that the left adjoint $p_!\colon \mathcal{C}(A) \to \mathcal{C}(B)$ exists more generally for any presheaf $B \in \mathrm{PSh}(T)$ and any $p \in \mathbf{U}(B)$; similarly, the Beck-Chevalley condition holds for any pullback square (2) in which $p \in \mathbf{U}(B)$, $B \in \mathrm{PSh}(T)$. Put differently, we can drop all representability conditions in the above lemma.

The following lemma is proved in a similar way and is left to the reader.

Lemma 2.3.16. *Let $\mathbf{U}$ be a class of T-∞-groupoids and let $\mathcal{C}$ and $\mathcal{D}$ be two T-∞-categories which admit $\mathbf{U}$-colimits. Then a T-functor F preserves $\mathbf{U}$-colimits if and only if for every $B \in T$ morphism $f\colon A \to B$ in $\mathbf{U}$, the Beck-Chevalley transformation $f_! \circ F(A) \Rightarrow F(B) \circ f_!$ is an equivalence. Moreover, in this case the Beck-Chevalley map is an equivalence more generally for any presheaf $B \in \mathrm{PSh}(T)$ and any $f \in \mathbf{U}(B)$.*

The dual statement for preserving $\mathbf{U}$-limits also holds. □

Using this we now give an easy criterion ensuring that cocontinuity is preserved under changing the indexing category:

Lemma 2.3.17. *Let $f\colon \mathrm{PSh}(S) \to \mathrm{PSh}(T)$ be a cocontinuous functor preserving pullbacks, let $\mathbf{U}$ be a class of S-∞-groupoids, and let $\mathbf{V}$ be a class of T-∞-groupoids such that $f(u) \in \mathbf{V}(f(B))$ for any $B \in S$ and $(u\colon A \to B) \in \mathbf{U}(B)$.*

Then $f^*\colon \mathrm{Cat}_T \to \mathrm{Cat}_S$ sends $\mathbf{V}$-cocomplete T-∞-categories to $\mathbf{U}$-cocomplete S-∞-categories and $\mathbf{V}$-cocontinuous T-functors to $\mathbf{U}$-cocontinuous S-functors.

Proof. Let $\mathcal{C}$ be a $\mathbf{V}$-cocomplete T-∞-category. If $B \in S$, $(u\colon A \to B) \in \mathbf{U}(S)$, then $u^*\colon (f^*\mathcal{C})(B) \to (f^*\mathcal{C})(A)$ agrees with $(f(u))^*\colon \mathcal{C}(f(B)) \to \mathcal{C}(f(A))$, so it admits a left adjoint by Remark 2.3.15 and $\mathbf{V}$-cocompleteness of $\mathcal{C}$. Similarly, given any pullback in $\mathrm{PSh}(S)$ as on the left

$$\begin{array}{ccc} A' & \xrightarrow{\alpha} & A \\ {\scriptstyle p'}\downarrow & \lrcorner & \downarrow{\scriptstyle p} \\ B' & \xrightarrow[\beta]{} & B \end{array} \qquad\qquad \begin{array}{ccc} f(A') & \xrightarrow{f(\alpha)} & f(A) \\ {\scriptstyle f(p')}\downarrow & \lrcorner & \downarrow{\scriptstyle f(p)} \\ f(B') & \xrightarrow[f(\beta)]{} & f(B) \end{array}$$

with B, B' representable and $p \in \mathbf{U}(B)$, also the diagram on the right is a pullback by assumption, and the Beck-Chevalley map $p'_!\alpha^* \Rightarrow \beta^* p_!$ for $f^*\mathcal{C}$ agrees with the Beck-Chevalley map $f(p')_! f(\alpha)^* \Rightarrow f(\beta)^* f(p)_!$ for $\mathcal{C}$. In particular, it is an equivalence again, so Lemma 2.3.14 shows that $f^*\mathcal{C}$ is $\mathbf{U}$-cocomplete.

The statement about cocontinuity follows similarly from the previous lemma. □

It turns out that the parametrized colimits indexed by the constant T-∞-categories and the T-∞-groupoids already determine all parametrized colimits.

Proposition 2.3.18 ([MW21, Proposition 4.7.1])**.** *A T-∞-category is T-cocomplete if and only if it admits fiberwise colimits and $\underline{\mathrm{Spc}}_T$-colimits. A T-functor between T-cocomplete T-∞-categories preserves T-colimits if and only if it preserves fiberwise colimits and $\underline{\mathrm{Spc}}_T$-colimits.* □

Corollary 2.3.19. *Let $f\colon \mathrm{PSh}(S) \to \mathrm{PSh}(T)$ as in Lemma 2.3.17. Then the restriction $f^*\colon \mathrm{Cat}_T \to \mathrm{Cat}_S$ sends T-cocomplete T-∞-categories to S-cocomplete S-∞-categories and T-cocontinuous T-functors to S-cocontinuous S-functors.*

Proof. Clearly, f^* preserves fiberwise cocompleteness and cocontinuity. The claim therefore follows from the previous proposition together with Lemma 2.3.17. $\square$

An important example of a T-(co)complete T-∞-category is the T-∞-category of T-spaces.

Example 2.3.20. The T-∞-category $\underline{\mathrm{Spc}}_T$ is both T-cocomplete and T-complete. Recall from Remark 2.1.16 that $\underline{\mathrm{Spc}}_T(B) \simeq \mathrm{PSh}(T)_{/B}$ for every $B \in T$, with functoriality given via pullback in $\mathrm{PSh}(T)$. The functor $f^*\colon \mathrm{PSh}(T)_{/B} \to \mathrm{PSh}(T)_{/A}$ admits a left adjoint given by postcomposition with f, and since $\mathrm{PSh}(T)$ is locally cartesian closed it also admits a right adjoint. It follows that $\underline{\mathrm{Spc}}_T$ admits all fiberwise limits and colimits. The left Beck-Chevalley condition is a consequence of the pasting law of pullback squares. The right Beck-Chevalley condition follows from this by passing to total mates.

Example 2.3.21. It follows directly from Example 2.3.20 that also the T-∞-categories $\underline{\mathrm{Spc}}_{T,*}$ and $\underline{\mathrm{Sp}}_T$ of pointed T-spaces and naive T-spectra are both T-cocomplete and T-complete, since they may be obtained from $\underline{\mathrm{Spc}}_T$ by pointwise tensoring with Spc_* and Sp inside Pr^{L}, respectively. For later use, we will make the left adjoint functors $p_!$ of $\underline{\mathrm{Spc}}_{T,*}$ explicit. First note that giving a basepoint to an object $(X, f : X \to A) \in \underline{\mathrm{Spc}}_T(A) \simeq \mathrm{PSh}(T)_{/A}$ amounts to providing a section $s\colon A \to X$ of the map f, so that we can identify objects of $\underline{\mathrm{Spc}}_{T,*}(A)$ with triples (X, f, s). Given a morphism $p\colon A \to B$ in $\mathrm{PSh}(T)$, we get $p_!(X, f, s) \simeq (X', f', s')$ defined via the following pushout diagram:

$$\begin{array}{ccccc} A & \xrightarrow{s} & X & \xrightarrow{f} & A \\ {\scriptstyle p}\downarrow & \ulcorner & \downarrow & & \downarrow{\scriptstyle p} \\ B & \xrightarrow{s'} & X' & \xrightarrow{f'} & B. \end{array}$$

We end this subsection with a discussion of categories of T-cocontinuous functors.

Definition 2.3.22. Let $\mathcal{C}, \mathcal{D}$ be T-cocomplete T-∞-categories, and let $A \in T$. We write $\underline{\mathrm{Fun}}^{\mathrm{L}}_T(\mathcal{C}, \mathcal{D})(A) \subset \underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D})$ for the full subcategory spanned by the $T_{/A}$-cocontinuous functors $\pi_A^* \mathcal{C} \to \pi_A^* \mathcal{D}$.

Lemma 2.3.23. *This defines a T-subcategory $\underline{\mathrm{Fun}}^{\mathrm{L}}_T(\mathcal{C}, \mathcal{D}) \subset \underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D})$.*

Proof. By Lemma 2.2.12 it suffices to show that for any $f\colon A \to B$ in T and $T_{/B}$-cocontinuous $F\colon \mathcal{C}' \to \mathcal{D}'$, the restriction $T_{/f}^* F$ is $T_{/A}$-cocontinuous. This follows at once from Corollary 2.3.19 as $(T_{/f})_!\colon \mathrm{PSh}(T_{/A}) \to \mathrm{PSh}(T_{/B})$ agrees up to equivalence with the pullback preserving functor $\mathrm{PSh}(T)_{/f}\colon \mathrm{PSh}(T)_{/A} \to \mathrm{PSh}(T)_{/B}$. $\square$

We will now give an alternative description in terms of the adjunct functors $F\colon \mathcal{C} \to \pi_{A*}\pi_A^* \mathcal{D} \simeq \underline{\mathrm{Fun}}_T(\underline{A}, \mathcal{D})$, which will in particular allow us to describe the value of $\underline{\mathrm{Fun}}^{\mathrm{L}}_T(\mathcal{C}, \mathcal{D})$ at non-representable presheaves. For this we will need:

Proposition 2.3.24 ([MW21, Proposition 4.3.1])**.** *Let K and $\mathcal{D}$ be T-∞-categories such that $\mathcal{D}$ admits all K-indexed parametrized limits. Then $\underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D})$ admits all K-indexed limits for any T-∞-category $\mathcal{C}$. Furthermore, the precomposition functor $i^*\colon \underline{\mathrm{Fun}}_T(\mathcal{C}', \mathcal{D}) \to \underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D})$ preserves K-indexed limits for every T-functor $i\colon \mathcal{C} \to \mathcal{C}'$. The dual statement for colimits is true as well.* $\square$

Combining this with Corollary 2.2.11 we get:

Corollary 2.3.25. *Let $\mathcal{C}, \mathcal{D}$ be T-∞-categories.*

1. *If $\mathcal{D}$ is $\mathbf{U}$-(co)complete for some $\mathbf{U} \subset \underline{\mathrm{Spc}}_T$, then so is $\underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D})$. Moreover, if $F\colon \mathcal{C} \to \mathcal{C}'$ is any functor, then $F^*\colon \underline{\mathrm{Fun}}_T(\mathcal{C}', \mathcal{D}) \to \underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D})$ is $\mathbf{U}$-(co)continuous.*
2. *If $\mathcal{D}$ is fiberwise (co)complete, then so is $\underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D})$. For any $\mathcal{C} \to \mathcal{C}'$, the restriction $\underline{\mathrm{Fun}}_T(\mathcal{C}', \mathcal{D}) \to \underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D})$ is fiberwise (co)continuous.* □

Proposition 2.3.26. *Let $\mathcal{C}$ be a T-cocomplete T-∞-category and let $\mathcal{D}$ be a $T_{/A}$-cocomplete T-∞-category. Then $\pi_{A*}\mathcal{D}$ is T-cocomplete, and a functor $F\colon \pi_A^* \to \mathcal{D}$ is $T_{/A}$-cocontinuous if and only if its adjunct $\tilde{F}\colon \mathcal{C} \to \pi_{A*}\mathcal{D}$ is T-cocontinuous.*

Proof. Assume first that F is $T_{/A}$-cocontinuous. Its adjunct $\tilde{F}$ is then given by

$$\mathcal{C} \xrightarrow{\eta} \pi_{A*}\pi_A^*\mathcal{C} \xrightarrow{\pi_{A*}F} \pi_{A*}\mathcal{D}\,.$$

Applying Corollary 2.3.19 to $A \times -\colon \mathrm{PSh}(T) \to \mathrm{PSh}(T)_{/A} \simeq \mathrm{PSh}(T_{/A})$, we see that $\pi_{A*}\mathcal{D}$ is T-cocomplete and $\pi_{A*}F$ is T-cocontinuous, so it suffices to show that η is T-cocontinuous. Unravelling definitions, this simply amounts to the functor $\mathcal{C} \to \mathcal{C}(A \times -)$ given by restriction along the projections $A \times B \to B$, which is clearly fiberwise cocontinuous. On the other hand, if $p\colon B' \to B$ is arbitrary, then the Beck-Chevalley map $p_!\eta \Rightarrow \eta p_!$ is precisely the Beck-Chevalley map $(A \times p)_! \circ \mathrm{pr}^* \Rightarrow \mathrm{pr}^* \circ p_!$ associated to the pullback

$$\begin{array}{ccc} A \times B' & \xrightarrow{\mathrm{pr}} & B' \\ {\scriptstyle A\times p}\big\downarrow & \lrcorner & \big\downarrow{\scriptstyle p} \\ A \times B & \xrightarrow[\mathrm{pr}]{} & B \end{array}$$

and hence an equivalence by T-cocompleteness of $\mathcal{C}$.

Conversely, assume $\tilde{F}$ is T-cocontinuous. Then F factors as

$$\pi_A^*\mathcal{C} \xrightarrow{\pi_A^*\tilde{F}} \pi_A^*\pi_{A*}\mathcal{D} \xrightarrow{\varepsilon} \mathcal{D},$$

where the first functor is $T_{/A}$-cocontinuous by Corollary 2.3.19 (or in fact, simply by definition). Similarly to the above, the counit is given by restriction along the unit maps $B \to A \times \pi_A(B)$, and the claim follows by observing that we also have pullbacks

$$\begin{array}{ccc} B' & \xrightarrow{\eta} & A \times \pi_A(B') \\ {\scriptstyle p}\big\downarrow & \lrcorner & \big\downarrow{\scriptstyle A\times\pi_A(p)} \\ B & \xrightarrow[\eta]{} & A \times \pi_A(B) \end{array}$$

in $\mathrm{PSh}(T_{/A})$ for any $p\colon B' \to B$ in $T_{/A}$. □

Remark 2.3.27. Analogously one sees that for a class $\mathbf{U}$ of T-∞-groupoids a functor $F\colon \pi_A^*\mathcal{C} \to \mathcal{D}$ is $\pi_A^*\mathbf{U}$-cocontinuous if and only if its adjunct is $\mathbf{U}$-cocontinuous.

Proposition 2.3.28. *Let $\mathcal{C}, \mathcal{D}$ be T-cocomplete T-∞-categories, let $X \in \mathrm{PSh}(T)$, and let $(F\colon \mathcal{C} \to \underline{\mathrm{Fun}}_T(\underline{X}, \mathcal{D})) \in \underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D})(X)$. Then F belongs to $\underline{\mathrm{Fun}}^{\mathrm{L}}_T(\mathcal{C}, \mathcal{D})(X)$ if and only if F is T-cocontinuous.*

Proof. If X is representable, this is immediate from Proposition 2.3.26. It therefore suffices to show that for general X a functor $F\colon \mathcal{C} \to \underline{\mathrm{Fun}}_T(\underline{X}, \mathcal{D})$ is T-cocontinuous if and only if for every map $A \to X$ from a representable the composite $\mathcal{C} \to \underline{\mathrm{Fun}}_T(\underline{A}, \mathcal{D})$ is T-cocontinuous.

The 'only if' part is immediate from Proposition 2.3.24. For the converse we observe that the functors $\underline{\mathrm{Fun}}_T(\underline{X}, \mathcal{D}) \to \underline{\mathrm{Fun}}_T(\underline{A}, \mathcal{D})$ exhibit the left hand side as a limit, and so are jointly conservative. It follows immediately that F is fiberwise cocontinuous. For the Beck-Chevalley condition we now let $p\colon C \to D$ be any map in T and consider

$$\begin{array}{ccccc} \mathcal{C}(D) & \xrightarrow{F} & \underline{\mathrm{Fun}}_T(\underline{X}, \mathcal{D})(D) & \longrightarrow & \underline{\mathrm{Fun}}_T(\underline{A}, \mathcal{D})(D) \\ {\scriptstyle p^*}\downarrow & & \downarrow{\scriptstyle p^*} & & \downarrow{\scriptstyle p^*} \\ \mathcal{C}(C) & \xrightarrow[F]{} & \underline{\mathrm{Fun}}_T(\underline{X}, \mathcal{D})(C) & \longrightarrow & \underline{\mathrm{Fun}}_T(\underline{A}, \mathcal{D})(C). \end{array}$$

By cocontinuity of the restriction functors, the mate of the right hand square is an equivalence, and so is the mate of the total rectangle by assumption. By the compatibility of mates with pasting we see that the mate of the left hand square is an equivalence after postcomposing with $\underline{\mathrm{Fun}}_T(\underline{X}, \mathcal{D})(C) \to \underline{\mathrm{Fun}}_T(\underline{A}, \mathcal{D})(C)$; the claim follows from joint conservativity again. $\square$

2.4. **Presentable T-∞-categories.** For the statement of various universal properties we need to restrict to *presentable* T-∞-categories. The notion of parametrized presentability was introduced by Nardin [Nar17] and was subsequently further developed by Hilman [Hil22] in the case where the ∞-category T is *orbital* (in the sense of Definition 4.2.2 below). A more general theory of parametrized presentability which works for arbitrary T was developed by Martini and Wolf [MW22] in terms of internal higher category theory. In this subsection, we will recall the main results on parametrized presentability.

Definition 2.4.1. A T-∞-category $\mathcal{C}$ is called *presentable* if the following two conditions hold:

(1) $\mathcal{C}$ is fiberwise presentable, meaning that the functor $\mathcal{C}\colon T^{\mathrm{op}} \to \mathrm{Cat}_\infty$ factors (necessarily uniquely) through Pr^{L};
(2) $\mathcal{C}$ is T-cocomplete.

Observe that fiberwise presentability guarantees that $\mathcal{C}$ has fiberwise colimits, so that condition (2) holds if and only if $\mathcal{C}$ admits $\underline{\mathrm{Spc}}_T$-indexed colimits.

By [MW22, Theorem A], this definition agrees with the definition of [MW22, Section 6] applied to the ∞-topos $\mathrm{PSh}(T)$. When T is orbital, this definition agrees with that of [Hil22, Section 4].

Remark 2.4.2. Any presentable T-∞-category $\mathcal{C}$ is automatically T-complete: fiberwise completeness and the existence of right adjoints $f_*\colon \mathcal{C}(A) \to \mathcal{C}(B)$ follow from fiberwise presentability, and for every pullback square of the form (2), the Beck-Chevalley map $\beta^* \circ p_* \Rightarrow p'_* \circ \alpha^*$ is the total mate of the Beck-Chevalley map $\alpha_! \circ p'^* \Rightarrow p^* \circ \beta_!$ and thus an equivalence.

Definition 2.4.3. We define $\mathrm{Pr}^{\mathrm{L}}_T$ to be the (non-full) subcategory of Cat_T spanned by the presentable T-∞-categories and left adjoint T-functors between them. Similarly we define $\mathrm{Pr}^{\mathrm{R}}_T$ to be the (non-full) subcategory of Cat_T spanned by the presentable T-∞-categories and right adjoint T-functors between them. There is a canonical equivalence $\mathrm{Pr}^{\mathrm{L}}_T \simeq (\mathrm{Pr}^{\mathrm{R}}_T)^{\mathrm{op}}$, see [MW22, Proposition 6.4.7].

Example 2.4.4. The T-∞-category $\underline{\mathrm{Spc}}_T$ of T-spaces is presentable: fiberwise presentability follows from presentability of $\mathrm{PSh}(T)$ while T-cocompleteness was argued for in Example 2.3.20.

Example 2.4.5. Let K be a small T-∞-category and let $\mathcal{C}$ be a presentable T-∞-category. Then the functor T-∞-category $\underline{\mathrm{Fun}}_T(K, \mathcal{C})$ is again presentable [MW22, Corollary 6.2.6], [Hil22, Lemma 4.6.1].

Example 2.4.6. Accessible Bousfield localizations of presentable T-∞-category are again presentable.

In more detail, let $\mathcal{C}$ be a presentable T-∞-category and let S be a parametrized family of morphisms in $\mathcal{C}$, i.e. a specification of a set $S(B)$ of morphisms of $\mathcal{C}(B)$ for every $B \in T$ such that $f^*(u) \in S(A)$ for every $u \in S(B)$ and every morphism $f\colon A \to B$ in T. An object $X \in \mathcal{C}(B)$ is said to be *S-local* if for every morphism $f\colon A \to B$ in T the object $f^*X \in \mathcal{C}(A)$ is $S(A)$-local, meaning that for every morphism $u\colon Y \to Z$ in $S(A)$ the induced map of spaces $\mathrm{Hom}_{\mathcal{C}(A)}(Z, f^*X) \to \mathrm{Hom}_{\mathcal{C}(A)}(Y, f^*X)$ is an equivalence. We let $\mathrm{Loc}_S(\mathcal{C}) \subseteq \mathcal{C}$ denote the full subcategory spanned by the S-local objects.

By [MW22, Lemma 6.1.3, Corollary 6.2.8] the T-∞-category $\mathrm{Loc}_S(\mathcal{C})$ is again presentable and the inclusion $\mathrm{Loc}_S(\mathcal{C}) \subset \mathcal{C}$ admits a left adjoint.

Remark 2.4.7. It follows from the previous three examples that the subcategory of S-local objects of a T-∞-category of T-presheaves $\underline{\mathrm{PSh}}_T(K) := \underline{\mathrm{Fun}}_T(K^{\mathrm{op}}, \underline{\mathrm{Spc}}_T)$ is presentable whenever S is a parametrized family of morphisms in $\underline{\mathrm{PSh}}_T(K)$. Conversely, any presentable T-∞-category is of this form, see [MW22, Theorem B], [Hil22, Theorem 4.1.2]

Proposition 2.4.8 (Adjoint functor theorem, [MW22, Proposition 6.3.1])**.** *If $\mathcal{C}$ and $\mathcal{D}$ are large T-∞-categories such that $\mathcal{C}$ is presentable and $\mathcal{D}$ is locally small, a T-functor $\mathcal{C} \to \mathcal{D}$ preserves T-colimits if and only if it admits a right adjoint.* □

Given a small T-∞-category K, the T-∞-category $\underline{\mathrm{PSh}}_T(K)$ is freely generated under parametrized colimits by K:

Theorem 2.4.9 ([MW21, Theorem 6.1.1])**.** *Let K be a small T-∞-category and let $\mathcal{D}$ be a T-cocomplete T-∞-category. Then restriction along the Yoneda embedding $y\colon K \hookrightarrow \underline{\mathrm{PSh}}_T(K)$ induces an equivalence of T-∞-categories*

$$\underline{\mathrm{Fun}}^{\mathrm{L}}_T(\underline{\mathrm{PSh}}_T(K), \mathcal{D}) \xrightarrow{\sim} \underline{\mathrm{Fun}}_T(K, \mathcal{D}).$$ □

Remark 2.4.10. Let $A \in T$ and let $f\colon \pi_A^*K \to \pi_A^*\mathcal{D}$ define an element of $\underline{\mathrm{Fun}}_T(K, \mathcal{D})(A)$, which by the proposition then extends to a left adjoint T-functor $F\colon \pi_A^*\underline{\mathrm{PSh}}_T(K) \to \pi_A^*\mathcal{D}$. As in the classical non-parametrized situation, the *right adjoint G* of F is actually easy to describe [MW21, Remark 7.1.4]: it is given by the composition

$$\pi_A^*\mathcal{D} \xrightarrow{y} \underline{\mathrm{Fun}}_{T_{/A}}(\pi_A^*\mathcal{D}^{\mathrm{op}}, \underline{\mathrm{Spc}}_{T_{/A}}) \xrightarrow{f^*} \underline{\mathrm{Fun}}_{T_{/A}}(\pi_A^*K, \underline{\mathrm{Spc}}_{T_{/A}}) \simeq \pi_A^*\underline{\mathrm{PSh}}_T(K).$$

Applying the theorem to the case where K is the terminal T-∞-category $\underline{1}$, we see that the T-∞-category $\underline{\mathrm{Spc}}_T$ is the free T-cocomplete T-∞-category on a single generator:

Corollary 2.4.11. *Let $\mathcal{D}$ be a T-cocomplete T-∞-category. Then evaluation at the terminal object $1 \in \mathrm{PSh}(T) = \Gamma(\underline{\mathrm{Spc}}_T)$ induces an equivalence of T-∞-categories*

$$\underline{\mathrm{Fun}}^{\mathrm{L}}_T(\underline{\mathrm{Spc}}_T, \mathcal{D}) \xrightarrow{\sim} \mathcal{D}\,. \qquad \square$$

3. The universal property of global spaces

In this section we will give a parametrized interpretation of unstable global homotopy theory in the sense of [Sch18, Chapter 1] with respect to *finite* groups. For this, the key idea will be to more generally consider unstable *G-global homotopy theory* in the sense of [Len20, Chapter 1] for finite groups G, which we recall in Subsection 3.1 below. In 3.2 we will then explain how these models for varying G assemble into a global ∞-category $\underline{\mathscr{S}}^{\mathrm{gl}}$ (in the sense of Example 2.1.3), and in Subsection 3.3 we will finally provide a universal description of $\underline{\mathscr{S}}^{\mathrm{gl}}$ as the free cocomplete global ∞-category generated by the terminal object.

3.1. A reminder on global and G-global homotopy theory.

Let G be a finite group; [Len20, Chapter 1] studies various models of *unstable G-global homotopy theory*. We will recall two of these models that will be particularly convenient for us:

Definition 3.1.1. We write $\mathcal{M}$ for the monoid (under composition) of injective self-maps of the countably infinite set $\omega := \{0, 1, \dots\}$.

The functor $\mathbf{SSet} \to \mathbf{Set}, X \mapsto X_0$ sending a simplicial set to its set of vertices admits a right adjoint E, given explicitly by $(EX)_n = X^{1+n}$ with functoriality induced by the identification $X^{1+n} \cong \mathrm{Hom}(\{0, \dots, n\}, X)$; equivalently, this is the nerve of the groupoid with objects X and a unique map between any two objects. As a right adjoint, E in particular preserves products, so $E\mathcal{M}$ inherits a natural monoid structure from $\mathcal{M}$.

We occasionally call the resulting simplicial monoid $E\mathcal{M}$ the 'universal finite group.' While $E\mathcal{M}$ is of course neither finite nor a group, this terminology is motivated by the fact that we can embed any finite group into $E\mathcal{M}$ in a particularly nice way:

Definition 3.1.2. Let H be a finite group. A countable H-set $\mathcal{U}$ is called a *complete H-set universe* if every other countable H-set embeds equivariantly into $\mathcal{U}$.

Definition 3.1.3. A finite subgroup $H \subset \mathcal{M}$ is called *universal* if the tautological H-action on ω makes the latter into a complete H-set universe.

Lemma 3.1.4 (See [Len20, Lemma 1.2.8])**.** *Let H be a finite group. Then there exists an injective homomorphism $i\colon H \to \mathcal{M}$ with universal image. If $j\colon H \to \mathcal{M}$ is another such map, then there exists an invertible $\varphi \in \mathcal{M}$ such that $i(h) = \varphi j(h)\varphi^{-1}$ for all $h \in H$.* $\square$

Remark 3.1.5. Somewhat loosely speaking, the reason to pass from the discrete monoid $\mathcal{M}$ to the simplicial monoid $E\mathcal{M}$ is to eliminate the indeterminacy of the invertible element φ in the above lemma, see [Len20, Subsections 1.2.2–1.2.3] for more details.

Definition 3.1.6. Let G be any group. We write $\boldsymbol{E\mathcal{M}}$-$\boldsymbol{G}$-**SSet** for the 1-category (or simplicially enriched category) of simplicial sets with a strict action of the simplicial monoid $E\mathcal{M}\times G$, together with the strictly $(E\mathcal{M}\times G)$-equivariant maps.

The category $\boldsymbol{E\mathcal{M}}$-$\boldsymbol{G}$-**SSet** will be our first model for G-global homotopy theory. In order to define the weak equivalences of this model structure we recall the following notation:

Notation 3.1.7. Let G_1, G_2 be groups, let $H \subset G_1$, and let $\varphi\colon H \to G_2$ be a homomorphism. The *graph subgroup* $\Gamma_{H,\varphi} \subset G_1 \times G_2$ is the subgroup $\{(h,\varphi(h)) : h \in H\}$. If X is a $(G_1\times G_2)$-simplicial set, then we abbreviate $X^\varphi := X^{\Gamma_{H,\varphi}}$, and similarly for $(G_1 \times G_2)$-equivariant maps.

Proposition 3.1.8. *The category* $\boldsymbol{E\mathcal{M}}$-$\boldsymbol{G}$-**SSet** *carries a (unique) combinatorial model structure in which a map is a weak equivalence or fibration if and only if f^φ is a weak homotopy equivalence or Kan fibration, respectively, for every universal subgroup $H \subset \mathcal{M}$ and homomorphism $\varphi\colon H \to G$. We call this the* G-global model structure *and its weak equivalences the* G-global weak equivalences*.*

Moreover, there is also a unique model structure on $\boldsymbol{E\mathcal{M}}$-$\boldsymbol{G}$-**SSet** *whose weak equivalences are the G-global weak equivalences and whose cofibrations are the* injective cofibrations*, i.e. the levelwise injections. We call this the* injective G-global model structure*.*

Proof. These are special cases of [Len20, Propositions 1.1.2 and 1.1.15], respectively; also see Corollary 1.2.34 of *op. cit.* for the former model structure. □

For $G = 1$ the above recovers a version of Schwede's global homotopy theory where one only considers equivariant information for finite groups ('$\mathcal{F}in$-global homotopy theory'), see Remark 3.1.14 below. On the other hand, for general finite G one can exhibit ordinary G-equivariant homotopy theory explicitly as a Bousfield localization of G-global homotopy theory, see [Len20, Subsection 1.2.6]. In this sense, G-global homotopy theory can be thought of as a 'synthesis' of the usual equivariant and global approaches.

Lemma 3.1.9 (See [Len20, Corollaries 1.2.76–1.2.79])**.** *Let $\alpha\colon G \to G'$ be any group homomorphism. Then the restriction functor $\alpha^*\colon$* $\boldsymbol{E\mathcal{M}}$-$\boldsymbol{G'}$-**SSet** $\to$ $\boldsymbol{E\mathcal{M}}$-$\boldsymbol{G}$-**SSet** *is homotopical and it takes part in Quillen adjunctions*

$$\alpha_!\colon \boldsymbol{E\mathcal{M}}\text{-}\boldsymbol{G}\text{-}\mathbf{SSet}_{G\text{-gl}} \rightleftarrows \boldsymbol{E\mathcal{M}}\text{-}\boldsymbol{G'}\text{-}\mathbf{SSet}_{G'\text{-gl}} : \alpha^*$$
$$\alpha^*\colon \boldsymbol{E\mathcal{M}}\text{-}\boldsymbol{G'}\text{-}\mathbf{SSet}_{\text{inj. }G'\text{-gl}} \rightleftarrows \boldsymbol{E\mathcal{M}}\text{-}\boldsymbol{G}\text{-}\mathbf{SSet}_{\text{inj. }G\text{-gl}} : \alpha_*.$$

Moreover, if α is injective*, then we also have Quillen adjunctions*

$$\alpha_!\colon \boldsymbol{E\mathcal{M}}\text{-}\boldsymbol{G}\text{-}\mathbf{SSet}_{\text{inj. }G\text{-gl}} \rightleftarrows \boldsymbol{E\mathcal{M}}\text{-}\boldsymbol{G'}\text{-}\mathbf{SSet}_{\text{inj. }G'\text{-gl}} : \alpha^*$$
$$\alpha^*\colon \boldsymbol{E\mathcal{M}}\text{-}\boldsymbol{G'}\text{-}\mathbf{SSet}_{G'\text{-gl}} \rightleftarrows \boldsymbol{E\mathcal{M}}\text{-}\boldsymbol{G}\text{-}\mathbf{SSet}_{G\text{-gl}} : \alpha_*.$$ □

Next, we come to another model in terms of suitable 'diagram spaces' that will become useful later to relate the unstable and stable theory to each other:

Definition 3.1.10. We write I for the category of finite sets and injections. Moreover, we write $\mathcal{I}$ for the simplicially enriched category obtained by applying $E\colon \mathbf{Set} \to \mathbf{SSet}$ to all hom-sets.

We write $\boldsymbol{\mathcal{I}}$**-SSet** for the category $\mathbf{Fun}(\mathcal{I}, \mathbf{SSet})$ of simplicially enriched functors $\mathcal{I} \to \mathbf{SSet}$. Moreover, if G is any group, then we write $\boldsymbol{G}$-$\boldsymbol{\mathcal{I}}$**-SSet** for the category of G-objects in $\boldsymbol{\mathcal{I}}$**-SSet**.

Construction 3.1.11. Let X be any $\mathcal{I}$-simplicial set. Then we define

$$X(\omega) := \operatorname*{colim}_{\substack{A \subset \omega \\ \text{finite}}} X(A).$$

This admits an $E\mathcal{M}$-action via the original functoriality of X in $\mathcal{I}$, see [Len20, Construction 1.4.14] for details, giving rise to a functor $\mathrm{ev}_\omega \colon \boldsymbol{\mathcal{I}}\text{-}\mathbf{SSet} \to \boldsymbol{E\mathcal{M}}\text{-}\mathbf{SSet}$. If G is any group, then we obtain a functor $\mathrm{ev}_\omega \colon \boldsymbol{G}\text{-}\boldsymbol{\mathcal{I}}\text{-}\mathbf{SSet} \to \boldsymbol{E\mathcal{M}}\text{-}\boldsymbol{G}\text{-}\mathbf{SSet}$ by pulling through the G-actions.

Theorem 3.1.12 (See [Len20, Proposition 1.4.3 and Theorem 1.4.30])**.** *There is a unique model structure on* $\boldsymbol{G}\text{-}\boldsymbol{\mathcal{I}}\text{-}\mathbf{SSet}$ *with*

- *weak equivalences those maps f for which $\mathrm{ev}_\omega f =: f(\omega)$ is a G-global weak equivalence,* and
- *acyclic fibrations those maps f for which $f(A)^\varphi$ is an acyclic Kan fibration for every finite set A, $H \subset \Sigma_A$, and $\varphi \colon H \to G$.*

We call this the G-global model structure *and its weak equivalences the* G-global weak equivalences *again.*

Moreover, the functor ev_ω *is the left half of a Quillen equivalence* $\boldsymbol{G}\text{-}\boldsymbol{\mathcal{I}}\text{-}\mathbf{SSet} \rightleftarrows \boldsymbol{E\mathcal{M}}\text{-}\boldsymbol{G}\text{-}\mathbf{SSet}_{\text{inj. } G\text{-gl}}$. □

Remark 3.1.13. One can also define a G-global model structure on the category $\boldsymbol{G}\text{-}\boldsymbol{I}\text{-}\mathbf{SSet}$ (whose weak equivalences are somewhat intricate). The forgetful functor $\boldsymbol{G}\text{-}\boldsymbol{\mathcal{I}}\text{-}\mathbf{SSet} \to \boldsymbol{G}\text{-}\boldsymbol{I}\text{-}\mathbf{SSet}$ is then the right half of a Quillen equivalence, see [Len20, Theorem 1.4.31].

Remark 3.1.14. Schwede [Sch18, Theorem 1.2.21] originally studied unstable global homotopy theory in terms of so-called *orthogonal spaces*, which are topologically enriched functors from the topological category L of finite dimensional inner product spaces and linear isometric embeddings into **Top**. While Schwede's *global equivalences* on $\boldsymbol{L}$**-Top** see equivariant information for all compact Lie groups, there is a natural notion of '$\mathcal{F}in$-global weak equivalences' [Len20, Definition 1.5.13], and with respect to these the evident forgetful functor $\boldsymbol{L}\text{-}\mathbf{Top} \to \boldsymbol{I}\text{-}\mathbf{SSet}$ becomes an equivalence of homotopy theories, see [Len20, Corollary 1.5.29]. In this sense, the above two models generalize global homotopy theory with respect to *finite* groups.

Finally, we again have suitable restriction functoriality analogous to Lemma 3.1.9. We will only recall one aspect that we will need later:

Lemma 3.1.15 (See [Len20, Lemma 1.4.40])**.** *Let $\alpha \colon G \to G'$ be any group homomorphism. Then the adjunction*

$$\alpha_! \colon \boldsymbol{G}\text{-}\boldsymbol{\mathcal{I}}\text{-}\mathbf{SSet} \rightleftarrows \boldsymbol{G'}\text{-}\boldsymbol{\mathcal{I}}\text{-}\mathbf{SSet} : \alpha^*$$

is a Quillen adjunction with homotopical right adjoint. □

3.2. **The global ∞-category of global spaces.** We will now bundle the ∞-categories associated to the above model categories into a *global ∞-category*, i.e. an ∞-category parametrized over the ∞-category Glo from Example 2.1.3:

Construction 3.2.1. We define the strict 2-functor $\boldsymbol{E\mathcal{M}}$-$\bullet$-**SSet** as the composition

$$\mathbf{Glo}^{\mathrm{op}} \xhookrightarrow{B} \mathbf{Grpd}^{\mathrm{op}} \xrightarrow{\mathrm{Fun}(-,\boldsymbol{E\mathcal{M}}\text{-}\mathbf{SSet})} \mathbf{Cat}; \tag{3}$$

put differently, this sends a finite group G to the 1-category $\boldsymbol{E\mathcal{M}}$-$\boldsymbol{G}$-**SSet**, a homomorphism $\alpha\colon G \to G'$ to the restriction map $\alpha^*\colon \boldsymbol{E\mathcal{M}}$-$\boldsymbol{G'}$-**SSet** $\to \boldsymbol{E\mathcal{M}}$-$\boldsymbol{G}$-**SSet**, and a 2-cell $g'\colon \alpha \Rightarrow \beta$ in Glo to the transformation $\alpha^* \Rightarrow \beta^*$ given by acting with g'.

We now want to obtain a *global ∞-category of global spaces* by pointwise localizing at the G-global weak equivalences. To this end we recall:

Definition 3.2.2. A *relative category* is a 1-category $\mathcal{C}$ together with a wide subcategory $W \subseteq \mathcal{C}$, whose morphisms we call *weak equivalences*. We let **RelCat** denote the $(2,1)$-category of relative categories, weak equivalence preserving functors, and natural isomorphisms, and we write RelCat for its Duskin nerve.

By Lemma 3.1.9, the restriction functor $\alpha^*\colon \boldsymbol{E\mathcal{M}}$-$\boldsymbol{G'}$-**SSet** $\to \boldsymbol{E\mathcal{M}}$-$\boldsymbol{G}$-**SSet** sends G'-global weak equivalences to G-global weak equivalences for any homomorphism $\alpha\colon G \to G'$. In particular, (3) lifts to a 2-functor into **RelCat** this way.

Construction 3.2.3. To every relative category $(\mathcal{C}, W)$, one can associate an ∞-category $\mathcal{C}[W^{-1}]$ together with a functor $\mathcal{C} \to \mathcal{C}[W^{-1}]$ that exhibits it as a Dwyer-Kan localization of $\mathcal{C}$ at W in the sense of [Lur17, Definition 1.3.4.1]. We will now recall the argument of [GM20, Section C.1] that the ∞-category $\mathcal{C}[W^{-1}]$ is in fact functorial in the pair $(\mathcal{C}, W)$.

Let $\iota\colon \mathrm{Cat}_\infty \to \mathrm{Spc}$ denote the left adjoint to the inclusion $\mathrm{Spc} \subseteq \mathrm{Cat}_\infty$ of ∞-groupoids into ∞-categories. Sending an ∞-category $\mathcal{C}$ to the adjunction counit $\iota\mathcal{C} \hookrightarrow \mathcal{C}$ refines to a functor

$$R\colon \mathrm{Cat}_\infty \to \mathrm{Fun}(\Delta^1, \mathrm{Cat}_\infty).$$

We let $L_\infty\colon \mathrm{Fun}(\Delta^1, \mathrm{Cat}_\infty) \to \mathrm{Cat}_\infty$ denote a left adjoint to this functor. By associating to a relative category $(\mathcal{C}, W)$ the inclusion $W \hookrightarrow \mathcal{C}$ and regarding both W and $\mathcal{C}$ as ∞-categories via their nerve, we obtain a functor $\mathrm{RelCat} \to \mathrm{Fun}(\Delta^1, \mathrm{Cat}_\infty)$. In particular we obtain a localization functor

$$L\colon \mathrm{RelCat} \to \mathrm{Fun}(\Delta^1, \mathrm{Cat}_\infty) \xrightarrow{L_\infty} \mathrm{Cat}_\infty\,.$$

It follows directly from the definition of L_∞ that L is on objects given by sending a relative category $(\mathcal{C}, W)$ to the Dwyer-Kan localization $L(\mathcal{C}, W) \simeq \mathcal{C}[W^{-1}]$.

Postcomposing with this, we get a global ∞-category $L\mathscr{C}$ from any global relative category $\mathscr{C}$, and this comes with a global functor $\mathscr{C} \to L\mathscr{C}$ that is pointwise a Dwyer-Kan localization. By uniqueness of adjoints, this actually pins down $L\mathscr{C}$ up to essentially unique equivalence; in particular, we can (and will at times) freely choose a specific construction of the above localization for a given $\mathscr{C}$.

Definition 3.2.4. We define the global ∞-category $\underline{\mathscr{S}}^{\mathrm{gl}}$ of *global spaces* as the composite

$$\mathrm{Glo}^{\mathrm{op}} = \mathrm{N}_\Delta(\mathbf{Glo})^{\mathrm{op}} \xrightarrow{\mathrm{N}_\Delta(\boldsymbol{E\mathcal{M}}\text{-}\bullet\text{-}\mathbf{SSet})} \mathrm{N}_\Delta(\mathbf{RelCat}) = \mathrm{RelCat} \xrightarrow{L} \mathrm{Cat}_\infty\,.$$

In particular, for a finite group G the ∞-category $\underline{\mathscr{S}}^{\mathrm{gl}}(G) =: \mathscr{S}^{\mathrm{gl}}_G$ is the ∞-category of G-global spaces and for a group homomorphism $\alpha\colon G \to G'$, the functor $\underline{\mathscr{S}}^{\mathrm{gl}}(\alpha)$ is induced by the restriction functor $\alpha^*\colon \boldsymbol{E\mathcal{M}}\text{-}\boldsymbol{G'}\text{-}\mathbf{SSet} \to \boldsymbol{E\mathcal{M}}\text{-}\boldsymbol{G}\text{-}\mathbf{SSet}$.

Analogously, we get a global ∞-category $\underline{\mathscr{S}}^{\mathrm{gl}}_{\mathcal{I}}$ sending G to the Dwyer-Kan localization of $\boldsymbol{G}\text{-}\boldsymbol{\mathcal{I}}\text{-}\mathbf{SSet}$, with functoriality via restrictions.

By design, the maps ev_ω are homotopical and strictly compatible with restrictions, and so they assemble into a strictly 2-natural transformation between functors $\mathbf{Glo}^{\mathrm{op}} \to \mathbf{RelCat}$. Upon localization, we therefore get a global functor $\underline{\mathscr{S}}^{\mathrm{gl}}_{\mathcal{I}} \to \underline{\mathscr{S}}^{\mathrm{gl}}$ that we again call ev_ω. Theorem 3.1.12 then implies:

Corollary 3.2.5. *The global functor* $\mathrm{ev}_\omega\colon \underline{\mathscr{S}}^{\mathrm{gl}}_{\mathcal{I}} \to \underline{\mathscr{S}}^{\mathrm{gl}}$ *is an equivalence of global ∞-categories.* □

3.3. Proof of Theorem A.

As a basis for the universal properties of special global Γ-spaces and global spectra, we will now relate the global ∞-category $\underline{\mathscr{S}}^{\mathrm{gl}}$ (defined above in terms of a purely model categorical construction) to the global ∞-category $\underline{\mathrm{Spc}}_{\mathrm{Glo}}$ (constructed using parametrized higher category theory alone). Namely we will prove:

Theorem 3.3.1. *The global ∞-category $\underline{\mathscr{S}}^{\mathrm{gl}}$ is presentable. Moreover, the essentially unique globally cocontinuous functor $\underline{\mathrm{Spc}}_{\mathrm{Glo}} \to \underline{\mathscr{S}}^{\mathrm{gl}}$ that sends the terminal object of $\mathrm{Spc}_{\mathrm{Glo}}(1)$ to the terminal object of $\mathscr{S}^{\mathrm{gl}} = \mathscr{S}^{\mathrm{gl}}_1$ is an equivalence.*

Together with Corollary 2.4.11 this will then immediately imply Theorem A from the introduction:

Theorem 3.3.2. *The presentable global ∞-category $\underline{\mathscr{S}}^{\mathrm{gl}}$ is freely generated under global colimits by $* \in \underline{\mathscr{S}}^{\mathrm{gl}}$, i.e. for any globally cocomplete global ∞-category $\mathcal{D}$ evaluating at $*$ induces an equivalence*

$$\underline{\mathrm{Fun}}^{\mathrm{L}}_{\mathrm{Glo}}(\underline{\mathscr{S}}^{\mathrm{gl}}, \mathcal{D}) \to \mathcal{D}$$

of global ∞-categories. □

Corollary 3.2.5 then shows:

Corollary 3.3.3. *The global ∞-category $\underline{\mathscr{S}}^{\mathrm{gl}}_{\mathcal{I}}$ is presentable, and it is freely generated under global colimits by $* \in \underline{\mathscr{S}}^{\mathrm{gl}}_{\mathcal{I}}$, i.e. for any globally cocomplete global ∞-category $\mathcal{D}$ evaluating at $*$ induces an equivalence*

$$\underline{\mathrm{Fun}}^{\mathrm{L}}_{\mathrm{Glo}}(\underline{\mathscr{S}}^{\mathrm{gl}}_{\mathcal{I}}, \mathcal{D}) \to \mathcal{D}$$

of global ∞-categories. □

The way Theorem 3.3.1 is phrased naturally suggests a proof strategy: show that the (fiberwise presentable) global ∞-category $\underline{\mathscr{S}}^{\mathrm{gl}}$ is globally cocomplete, use the universal property to construct the map, and then check that it is an equivalence. In fact, one can use the functoriality properties of Lemma 3.1.9 together with [Len20, Proposition 1.1.22] to verify global cocompleteness, and it is not hard to show using some adjunction yoga that the resulting functor sends corepresented objects to the standard 'generators' of G-global homotopy theory (see Proposition 3.3.5 below) while a concrete computation reveals that the mapping spaces on both sides are *abstractly* equivalent. However, proving that actually the universal functor induces equivalences between these mapping spaces is a totally different story, and in fact the authors do not know a direct argument for this.

Instead, our proof of the theorem will proceed backwards: we will construct an equivalence between $\underline{\mathscr{S}}^{\mathrm{gl}}$ and $\underline{\mathrm{Spc}}_{\mathrm{Glo}}$ by hand, and deduce the remaining statements from this. Since this comparison is somewhat lengthy, let us outline the general strategy first: by definition, $\underline{\mathrm{Spc}}_{\mathrm{Glo}}$ is levelwise given by ∞-categories of presheaves, and the first step will be to likewise express the levels of $\underline{\mathscr{S}}^{\mathrm{gl}}$ in terms of *model categories* of presheaves. To complete the proof, we will then give a comparison between the indexing categories on both sides, as well as a comparison between presheaves in the model categorical and ∞-categorical setting.

3.3.1. *The G-global Elmendorf Theorem.* Recall that the classical *Elmendorf Theorem* [Elm83] expresses the homotopy theory of G-CW-complexes in terms of *fixed point systems*, yielding a presheaf model of unstable G-equivariant homotopy theory. We will now recall a G-global version of this, which is most easily formulated using the model of $E\mathcal{M}$-G-simplicial sets:

Construction 3.3.4. Let G be finite. We write $\mathbf{O}^{\mathrm{gl}}_G$ for the full simplicial subcategory of $\boldsymbol{E\mathcal{M}}$-$\boldsymbol{G}$-**SSet** spanned by the objects $E\mathcal{M}\times_\varphi G := (E\mathcal{M}\times G)/H$ for all universal subgroups $H\subset\mathcal{M}$ and homomorphisms $\varphi\colon H\to G$, where H acts on $E\mathcal{M}$ from the right in the evident way and on G from the right via φ.

We now define a functor

$$\Phi\colon \boldsymbol{E\mathcal{M}}\text{-}\boldsymbol{G}\text{-}\mathbf{SSet}\to\mathbf{Fun}((\mathbf{O}^{\mathrm{gl}}_G)^{\mathrm{op}},\mathbf{SSet}),$$

where **Fun** denotes the 1-category of simplicially enriched functors, via the formula $\Phi(X)(E\mathcal{M}\times_\varphi G)=\mathrm{maps}(E\mathcal{M}\times_\varphi G,X)$ with the evident (enriched) functoriality in each variable, i.e. Φ is the composition

$$\boldsymbol{E\mathcal{M}}\text{-}\boldsymbol{G}\text{-}\mathbf{SSet}\xrightarrow{\text{Yoneda}}\mathbf{Fun}(\boldsymbol{E\mathcal{M}}\text{-}\boldsymbol{G}\text{-}\mathbf{SSet}^{\mathrm{op}},\mathbf{SSet})\xrightarrow{\text{restriction}}\mathbf{Fun}((\mathbf{O}^{\mathrm{gl}}_G)^{\mathrm{op}},\mathbf{SSet}).$$

Proposition 3.3.5. *For any finite group G the above functor Φ is homotopical and the right half of a Quillen equivalence for the projective model structure on the target. In particular, it descends to an equivalence between the ∞-categorical localization at the G-global weak equivalences and the ∞-categorical localization at the levelwise weak homotopy equivalences.*

Proof. This is a special case of [Len20, Corollary 1.1.13]. □

Remark 3.3.6. We can describe the simplicial category $\mathbf{O}^{\mathrm{gl}}_G$ combinatorially as follows, see also [Len20, Remark 1.2.40]: n-simplices of $\mathrm{maps}(E\mathcal{M}\times_\varphi G,E\mathcal{M}\times_\psi G)$ correspond bijectively to n-simplices $[u_0,\dots,u_n;g]\in(E\mathcal{M}\times_\psi G)^\varphi$ via evaluation at $[1;1]\in E\mathcal{M}\times_\varphi G$; note that the right hand side is the nerve of a groupoid (as H acts freely on $E\mathcal{M}$), so $\mathbf{O}^{\mathrm{gl}}_G$ can be equivalently viewed a $(2,1)$-category. Under this correspondence, composition is given by $[u_0,\dots,u_n;g][u'_0,\dots,u'_n;g']=[u'_0u_0,\dots,u'_nu_n;g'g]$ (note the flipped order of multiplication).

More generally, if X is any $E\mathcal{M}$-G-simplicial set, then evaluation at $[1;1]$ induces a natural isomorphism $\varepsilon\colon\Phi(X)(E\mathcal{M}\times_\varphi G)=\mathrm{maps}(E\mathcal{M}\times_\varphi G,X)\to X^\varphi$. A direct computation shows that under this isomorphism restriction along an $(n+1)$-cell

$[u_0, \ldots, u_n; g] : E\mathcal{M} \times_\varphi G \to E\mathcal{M} \times_\psi G$ in $\mathbf{O}_G^{\mathrm{gl}}$ corresponds to action by the same element, i.e. the following diagram commutes:

$$\begin{array}{ccc} \Phi(X)(E\mathcal{M} \times_\psi G) & \xrightarrow{\Phi[u_0,\ldots,u_n;g]} & \Phi(X)(E\mathcal{M} \times_\varphi G) \\ {\scriptstyle\varepsilon}\downarrow & & \downarrow{\scriptstyle\varepsilon} \\ X^\psi & \xrightarrow[(u_0,\ldots,u_n;g).-]{} & X^\varphi. \end{array} \tag{4}$$

3.3.2. *Comparisons of enriched presheaves.* While one can extend the assignment $G \mapsto \mathbf{O}_G^{\mathrm{gl}}$ to a strict 2-functor in Glo, and so assemble the localizations of the categories $\mathbf{Fun}((\mathbf{O}_G^{\mathrm{gl}})^{\mathrm{op}}, \mathbf{SSet})$ into a global ∞-category, the maps Φ will not be strictly natural with respect to this structure, but only pseudonatural. In order to avoid talking about all the coherences required to make this precise, we will now give a more 'combinatorial' version of the simplicial categories $\mathbf{O}_G^{\mathrm{gl}}$ and the functors Φ that will also become relevant in Section 5.

Construction 3.3.7. Let G be a finite group. We define a strict $(2,1)$-category $\mathfrak{O}_G^{\mathrm{gl}}$ as follows: an object of $\mathfrak{O}_G^{\mathrm{gl}}$ is a pair (H, φ) of a universal subgroup $H \subset \mathcal{M}$ and a homomorphism $\varphi\colon H \to G$. For any two such objects $(H, \varphi), (K, \psi)$ the hom-category $\mathbf{Hom}((H, \varphi), (K, \psi))$ has objects the triples (u, g, σ) with $u \in \mathcal{M}$, $g \in G$ and $\sigma\colon H \to K$ a homomorphism such that $hu = u\sigma(h)$ for all $h \in H$ and moreover $\varphi = c_g\psi\sigma$, where c_g denotes conjugation by g. If (u', g', σ') is another object of the hom-category, then a morphism $(u, g, \sigma) \to (u', g', \sigma')$ is a $k \in K$ such that $\sigma' = c_k\sigma$ and $g'\psi(k) = g$. Composition in $\mathbf{Hom}((H, \varphi), (K, \psi))$ is induced by multiplication in K; we omit the easy verification that this is a well-defined groupoid.

If (L, ζ) is another object and $(u_1, g_1, \sigma_1)\colon (H, \varphi) \to (K, \psi)$, $(u_2, g_2, \sigma_2)\colon (K, \psi) \to (L, \zeta)$ are composable maps, then we define their composition as $(u_1u_2, g_1g_2, \sigma_2\sigma_1)$ (note the flipped order of composition in the first two components!); this is indeed a map $(H, \varphi) \to (L, \zeta)$ as $hu_1u_2 = u_1\sigma_1(h)u_2 = u_1u_2\sigma_2\sigma_1(h)$ for all $h \in H$ and moreover $\varphi = c_{g_1}\psi\sigma_1 = c_{g_1g_2}\zeta\sigma_2\sigma_1$.

Finally, if $(u_1', g_1', \sigma_1')\colon (H, \varphi) \to (K, \psi)$ and $(u_2', g_2', \sigma_2')\colon (K, \psi) \to (L, \zeta)$ are further morphisms and $k_1\colon (u_1, g_1, \sigma_1) \to (u_1', g_1', \sigma_1')$, $k_2\colon (u_2, g_2, \sigma_2) \to (u_2', g_2', \sigma_2')$ are 2-cells, then the composite of k_1 and k_2 is $k_2\sigma_2(k_1)$; note that this is indeed well-defined as $\sigma_2'\sigma_1' = c_{k_2}\sigma_2c_{k_1}\sigma_1 = c_{k_1\sigma_2(k_2)}\sigma_2\sigma_1$ while $g_1g_2 = g_1'\psi(k_1)g_2'\zeta(k_2) = g_1'g_2'\zeta\sigma_2'(k_1)\zeta(k_2) = g_1'g_2'\zeta(\sigma_2'(k_1)k_2) = g_1'g_2'\zeta(k_2\sigma_2(k_1))$ where the second equality uses that (u_2', g_2', σ_2') is a morphism and the final equality uses that k_2 is a 2-cell.

We omit the straight-forward verification that this is suitably associative and unital with units the maps of the form $(1, 1, \mathrm{id})$, making $\mathfrak{O}_G^{\mathrm{gl}}$ into a strict $(2,1)$-category.

Construction 3.3.8. We define $\mu\colon \mathfrak{O}_G^{\mathrm{gl}} \to \mathbf{O}_G^{\mathrm{gl}}$ as follows: an object (H, φ) is sent to $E\mathcal{M} \times_\varphi G$, a morphism $(u, g, \sigma)\colon (H, \varphi) \to (K, \psi)$ is sent to the map $E\mathcal{M} \times_\varphi G \to E\mathcal{M} \times_\psi G$ represented by $[u; g]$ while a 2-cell $k\colon (u, g, \sigma) \to (u', g', \sigma')$ is sent to $[u'k, u; g]$.

Lemma 3.3.9. *The above μ is well-defined (i.e. these are indeed morphisms and 2-cells in $\mathbf{O}_G^{\mathrm{gl}}$) and an equivalence of $(2,1)$-categories.*

Proof. First observe that $[u; g]$ is indeed φ-fixed as $[hu; \varphi(h)g] = [u\sigma(h); g\psi\sigma(h)] = [u; g]$ by definition of the morphisms of $\mathfrak{O}_G^{\mathrm{gl}}$; moreover, any 1-cell in the target is of this form by [Len20, Lemma 1.2.38]. On the other hand, Lemma 1.2.74 of *op. cit.* shows that $[u'k, u; g]$ is indeed a 2-cell $[u; g] \Rightarrow [u'; g']$ and that this assignment is bijective. Thus, it only remains to show that μ is a strict 2-functor.

To prove that $\mu\colon \mathbf{Hom}((H,\varphi),(K,\psi)) \to (E\mathcal{M} \times_\psi G)^\varphi$ is a functor, it suffices to prove compatibility with composition (as both sides are groupoids), for which we note that for all $k\colon (u, g, \sigma) \to (u', g', \sigma')$ and $k'\colon (u', g', \sigma') \to (u'', g'', \sigma'')$

$$\begin{aligned}\mu(k')\mu(k) &= [u''k', u'; g'][u'k, u; g] = [u''k'k, u'k; \underbrace{g'\psi(k)}_{=g}][u'k, u; g] = [u''k'k, u; g]\\ &= \mu(k'k).\end{aligned}$$

Next, we have to show that μ is compatible with horizontal composition of 2-cells, hence in particular with composition of 1-cells. For this we note that if $k\colon (u_1, g_1, \sigma_1) \Rightarrow (u_1', g_1', \sigma_1')$ is a 2-cell between morphisms $(H, \varphi) \to (K, \psi)$ and $\ell\colon (u_2, g_2, \sigma_2) \Rightarrow (u_2', g_2', \sigma_2')$ is a 2-cell between morphisms $(K, \psi) \to (L, \zeta)$, then the horizontal composition $\mu(\ell) \odot \mu(k)$ is given by

$$\begin{aligned}[u_2'\ell, u_2, g_2] \odot [u_1'k, u_1; g_1] &= [u_1'ku_2'\ell, u_1u_2; g_1g_2] = [u_1'u_2'\sigma_2'(k)\ell, u_1u_2; g_1g_2]\\ &= [u_1'u_2'\ell\sigma_2(k), u_1u_2; g_1g_2]\end{aligned}$$

where the final equality uses that $\sigma_2'(k)\ell = \ell\sigma_2(k)$ as ℓ is a 2-cell. On the other hand, by definition $\ell \odot k = \ell\sigma_2(k)\colon (u_1u_2, g_1g_2, \sigma_2\sigma_1) \to (u_1'u_2', g_1'g_2', \sigma_2'\sigma_1')$, so $\mu(\ell \odot k) = \mu(\ell) \odot \mu(k)$ as desired.

Finally, $\mu(1, 1, \mathrm{id}) = [1; 1]$ by construction, i.e. μ also preserves identity 1-cells. □

Construction 3.3.10. Let G be a finite group. We define $\Psi\colon \boldsymbol{E\mathcal{M}}\text{-}\boldsymbol{G}\text{-}\mathbf{SSet} \to \mathbf{PSh}(\mathfrak{O}_G^{\mathrm{gl}}) := \mathbf{Fun}((\mathfrak{O}_G^{\mathrm{gl}})^{\mathrm{op}}, \mathbf{SSet})$ as follows: for any $E\mathcal{M}$-G-simplicial set X, the enriched functor $\Psi(X)\colon (\mathfrak{O}_G^{\mathrm{gl}})^{\mathrm{op}} \to \mathbf{SSet}$ is given on objects by $\Psi(X)(H, \varphi) = X^\varphi \subset X$; if (K, ψ) is another object, then we send an n-simplex

$$(u_0, g_0, \sigma_0) \xRightarrow{k_1} (u_1, g_1, \sigma_1) \xRightarrow{k_2} \cdots \xRightarrow{k_n} (u_n, g_n, \sigma_n) \in \mathrm{maps}((H,\varphi),(K,\psi))_n \quad (5)$$

to the action of $(u_nk_n \cdots k_1, u_{n-1}k_{n-1} \cdots k_1, \dots, u_1k_1, u_0; g_0)$ on X, cf. Remark 3.3.6. If $f\colon X \to Y$ is any map of $E\mathcal{M}$-G-simplicial sets, then we define $\Psi(f)$ via $\Psi(f)(H, \varphi) = f^\varphi$.

Proposition 3.3.11. *The assignment $\Psi\colon \boldsymbol{E\mathcal{M}}\text{-}\boldsymbol{G}\text{-}\mathbf{SSet} \to \mathbf{PSh}(\mathfrak{O}_G^{\mathrm{gl}})$ is well-defined (i.e. $\Psi(X)$ is a simplicially enriched functor and $\Psi(f)$ is an enriched natural transformation) and constitutes a functor. Furthermore, it descends to an equivalence on ∞-categorical localizations.*

Proof. We will simultaneously prove that Ψ is well-defined and that it is isomorphic to the composite

$$\boldsymbol{E\mathcal{M}}\text{-}\boldsymbol{G}\text{-}\mathbf{SSet} \xrightarrow{\Phi} \mathbf{PSh}(\mathbf{O}_G^{\mathrm{gl}}) \xrightarrow{\mu^*} \mathbf{PSh}(\mathfrak{O}_G^{\mathrm{gl}});$$

the claim then follows from Proposition 3.3.5 together with Lemma 3.3.9.

To prove this, we first fix an $E\mathcal{M}$-G-simplicial set X, and we will show that $\Psi(X)$ is a well-defined simplicial functor isomorphic to $\Phi(X) \circ \mu$. To this end, we recall that we have for every $(H, \varphi) \in \mathfrak{O}_G^{\mathrm{gl}}$ an isomorphism

$$\Phi(X)(\mu(H,\varphi)) = \mathrm{maps}(E\mathcal{M} \times_\varphi G, X) \xrightarrow{\varepsilon} X^\varphi = \Psi(X)(H,\varphi)$$

given by evaluation at $[1;1]$. It follows formally that there is a unique way to extend the assignment $(H,\varphi)\mapsto X^\varphi$ to a simplicially enriched functor $(\mathfrak{O}^{\mathrm{gl}}_G)^{\mathrm{op}}\to \mathbf{SSet}$ in such a way that the ε's assemble into an enriched natural isomorphism from $\Phi(X)\circ\mu$, namely in terms of the composites

$$\begin{aligned}\mathrm{maps}_{\mathfrak{O}^{\mathrm{gl}}}\big((H,\varphi),(K,\psi)\big) &\xrightarrow{\mu} \mathrm{maps}_{\mathbf{O}^{\mathrm{gl}}}(E\mathcal{M}\times_\varphi G, E\mathcal{M}\times_\psi G)\\ &\xrightarrow{\Phi} \mathrm{maps}_{\mathbf{SSet}}\big(\mathrm{maps}_{\boldsymbol{E\mathcal{M}}\text{-}\boldsymbol{G}\text{-}\mathbf{SSet}}(E\mathcal{M}\times_\psi G, X),\\ &\qquad\qquad \mathrm{maps}_{\boldsymbol{E\mathcal{M}}\text{-}\boldsymbol{G}\text{-}\mathbf{SSet}}(E\mathcal{M}\times_\varphi G, X)\big)\\ &\xrightarrow{\varepsilon_*(\varepsilon^{-1})^*} \mathrm{maps}_{\mathbf{SSet}}(X^\psi, X^\varphi)\end{aligned}$$

and we only have to show that this recovers the above definition of Ψ. By commutativity of (4) this then amounts to saying that

$$\mathrm{maps}\big((H,\varphi),(K,\psi)\big)\xrightarrow{\mu}\mathrm{maps}(E\mathcal{M}\times_\varphi G, E\mathcal{M}\times_\psi G)\xrightarrow{\varepsilon}(E\mathcal{M}\times_\psi G)^\varphi\subset E\mathcal{M}\times_\psi G$$

sends (5) to $(u_nk_n\cdots k_1,\dots,u_1k_1,u_0;g_0)$. As $E\mathcal{M}\times_\psi G$ is the nerve of a groupoid, it will be enough to show this after restricting to each edge $0\to m$ ($0\le m\le n$), i.e. that $\mu(k_m\cdots k_0)=(u_mk_m\cdots k_1,u_0;g_0)$. However, this is precisely the definition.

Thus, we have altogether shown that $\Psi(X)$ is indeed a well-defined simplicial functor and that the maps ε assemble into an isomorphism $\Psi(X)\cong\Phi(X)\circ\mu$. We can now show that Ψ is a well-defined functor: indeed, if $f\colon X\to Y$ is $(E\mathcal{M}\times G)$-equivariant, then $\Psi(f)$ is enriched natural as the enriched functor structure on both sides is given by acting with simplices of $E\mathcal{M}\times G$. It is then clear that Ψ preserves composition and identities as this can be checked after evaluating at each (H,φ).

Finally, we have to establish that the isomorphisms ε are natural in X. However, we can again check this after evaluating at each (H,φ), where this is obvious. $\square$

Construction 3.3.12. We extend the assignment $G\mapsto\mathfrak{O}^{\mathrm{gl}}_G$ to a strict $(2,1)$-functor $\mathfrak{O}^{\mathrm{gl}}_\bullet\colon\mathbf{Glo}\to\mathbf{Cat}_\Delta$ into the 2-category of simplicial categories as follows: if $\alpha\colon G\to G'$ is a homomorphism, then $\alpha_!\colon\mathfrak{O}^{\mathrm{gl}}_G\to\mathfrak{O}^{\mathrm{gl}}_{G'}$ is given on objects by $\alpha_!(H,\varphi)=(H,\alpha\varphi)$, on 1-cells by $\alpha_!(u,g,\sigma)=(u,\alpha(g),\sigma)$, and on 2-cells by the identity; we omit the easy verification that this is well-defined and strictly functorial in α. Moreover, if $g\in G'$ defines a natural transformation $\alpha_1\Rightarrow\alpha_2$ (i.e. $\alpha_2=c_g\alpha_1$), then we define the natural transformation $g_!\colon\alpha_{1!}\Rightarrow\alpha_{2!}$ on (H,φ) as $(1,g^{-1},\mathrm{id}_H)\colon(H,\alpha_1\varphi)\to(H,\alpha_2\varphi)$. We again omit the easy verification that this is well-defined and yields a strict 2-functor.

This 2-functor structure then induces a 2-functor structure on the assignment $G\mapsto(\mathfrak{O}^{\mathrm{gl}}_G)^{\mathrm{op}}$; note that in this the 2-cells get inverted, i.e. $g\colon\alpha_1\Rightarrow\alpha_2$ is now sent to the natural transformation $g_!^{\mathrm{op}}$ given pointwise by $(1,g,\mathrm{id})$.

Proposition 3.3.13. *The maps* Ψ *are strictly* 2*-natural in* $\mathbf{Glo}$.

Proof. Let us first check 1-naturality, i.e. that for every $\alpha\colon G\to G'$ the diagram

$$\begin{array}{ccc}\boldsymbol{E\mathcal{M}}\text{-}\boldsymbol{G'}\text{-}\mathbf{SSet} & \xrightarrow{\alpha^*} & \boldsymbol{E\mathcal{M}}\text{-}\boldsymbol{G'}\text{-}\mathbf{SSet}\\ {\scriptstyle\Psi}\downarrow & & \downarrow{\scriptstyle\Psi}\\ \mathbf{PSh}(\mathfrak{O}^{\mathrm{gl}}_{G'}) & \xrightarrow[(\alpha_!)^*]{} & \mathbf{PSh}(\mathfrak{O}^{\mathrm{gl}}_G)\end{array}$$

of ordinary categories commutes.

The above diagram commutes on the level of objects: Let X be an $E\mathcal{M}$-G-simplicial set; we have to show that $\Psi(\alpha^*X) = \Psi(X) \circ \alpha_!$. On the level of objects, this just amounts to the relation $(\alpha^*X)^\varphi = X^{\alpha\circ\varphi}$ for all $(H, \varphi\colon H \to G) \in \mathfrak{O}^{\mathrm{gl}}_G$. To prove commutativity on the level of morphism spaces, we let (K, ψ) be any other object and we consider an n-simplex

$$(u_\bullet, g_\bullet, \sigma_\bullet) := \big((u_0, g_0, \sigma_0) \xRightarrow{k_1} (u_1, g_1, \sigma_1) \xRightarrow{k_2} \cdots \xRightarrow{k_n} (u_n, g_n, \sigma_n)\big)$$

of maps$((H, \varphi), (K, \psi))$. Then $\Psi(\alpha^*X)(u_\bullet, g_\bullet, \sigma_\bullet)$ is by definition given by acting with $(u_nk_n \cdots k_1, \dots, u_1k_1, u_0; g_0) \in E\mathcal{M}_n \times G$ on α^*X, or equivalently by acting with $(u_nk_n \cdots k_1, \dots, u_1k_1, u_0; \alpha(g_0)) \in E\mathcal{M}_n \times G'$ on X. As $\alpha_!\colon \mathfrak{O}^{\mathrm{gl}}_G \to \mathfrak{O}^{\mathrm{gl}}_{G'}$ sends $(u_\bullet, g_\bullet, \sigma_\bullet)$ to

$$(u_0, \alpha(g_0), \sigma_0) \xRightarrow{k_1} (u_1, \alpha(g_1), \sigma_1) \xRightarrow{k_2} \cdots \xRightarrow{k_n} (u_n, \alpha(g_n), \sigma_n)$$

by definition, we see that $\Psi(X)(\alpha_!(u_\bullet, g_\bullet, \sigma_\bullet))$ is given by acting with the same element. Since in addition both $\Psi(X)(\alpha_!(u_\bullet, g_\bullet, \sigma_\bullet))$ and $\Psi(\alpha^*X)(u_\bullet, g_\bullet, \sigma_\bullet)$ are (higher) maps between the same two objects, this completes the proof that they agree, so that $\Psi(\alpha^*X) = \Psi(X) \circ \alpha_!$ as desired.

The above diagram commutes on the level of morphisms: As we already know that the diagram commutes on the level of objects, it is enough to check the claim after evaluating at each (H, φ). However, in this case both paths through the diagram send a morphism $f\colon X \to Y$ to the restriction $X^{\alpha\varphi} \to Y^{\alpha\varphi}$ of f.

Finally, we can now very easily prove 2-*naturality* by the same argument: namely, it only remains to show that for every 2-cell $g\colon \alpha_1 \Rightarrow \alpha_2$ in Glo, every $E\mathcal{M}$-G-simplicial set X, and every $(H, \varphi) \in \mathfrak{O}^{\mathrm{gl}}_G$ the maps $\Psi(X)(g_!^{\mathrm{op}}\colon (H, \alpha_2\varphi) \to (H, \alpha_1\varphi))$ and $\Psi(g.{-}\colon \alpha_1^*X \to \alpha_2^*X)(H, \varphi)$ agree. However, plugging in the definitions, both are simply given by acting with g on X. ☐

Construction 3.3.14. Let G be a finite group. We define a strict 2-functor $\gamma\colon \mathfrak{O}^{\mathrm{gl}}_G \to \mathbf{Glo}_{/G}$ into the 2-categorical slice as follows: an object (H, φ) is sent to $\varphi\colon H \to G$ and a morphism $(u, g, \sigma)\colon (H, \varphi) \to (K, \psi)$ is sent to the morphism

$$\begin{array}{ccc} H & \xrightarrow{\quad\sigma\quad} & K; \\ & {\scriptstyle g^{-1}}\,\Nearrow & \\ {\scriptstyle\varphi}\searrow & & \swarrow{\scriptstyle\psi} \\ & G & \end{array} \tag{6}$$

note that g^{-1} indeed defines such a 2-cell in **Glo** since $\varphi = c_g\sigma\psi$ by assumption, whence $\sigma\psi = c_{g^{-1}}\varphi$. Finally, a 2-cell $k\colon (u, g, \sigma) \Rightarrow (u, g, \sigma)$ is sent to the 2-cell $k\colon \sigma \Rightarrow \sigma'$.

Lemma 3.3.15. *For any finite G, γ defines an equivalence $\mathfrak{O}^{\mathrm{gl}}_G \simeq \mathbf{Glo}_{/G}$ of strict $(2,1)$-categories.*

Proof. One easily checks by plugging in the definitions that γ is indeed a strict 2-functor. Essential surjectivity of γ follows from the fact that any finite group is isomorphic to a universal subgroup (Lemma 3.1.4). Moreover, given a general 1-cell as depicted in (6), there exists by [Len20, Corollary 1.2.39] a $u \in \mathcal{M}$ with $hu = u\sigma(h)$ for all $h \in H$; (u, g, σ) then clearly defines a 1-cell $(H, \varphi) \to (K, \psi)$ in

$\mathfrak{O}^{\mathrm{gl}}_G$, and this is a preimage of (6). This shows that γ is essentially surjective on hom groupoids. Finally, γ is bijective on 2-cells by direct inspection. ☐

Lemma 3.3.16. *The maps γ define a strictly 2-natural transformation $\mathfrak{O}^{\mathrm{gl}}_\bullet \Rightarrow$ $\mathbf{Glo}_{/\bullet}$.*

Proof. Let us first show that γ is 1-natural, i.e. for every homomorphism $\alpha\colon G \to G'$ the diagram

$$\begin{array}{ccc} \mathfrak{O}^{\mathrm{gl}}_G & \xrightarrow{\gamma} & \mathbf{Glo}_{/G} \\ {\scriptstyle \alpha_!}\downarrow & & \downarrow{\scriptstyle \mathbf{Glo}_{/\alpha}} \\ \mathfrak{O}^{\mathrm{gl}}_{G'} & \xrightarrow[\gamma]{} & \mathbf{Glo}_{/G'} \end{array}$$

of strict 2-functors commutes strictly. This just amounts to plugging in the definitions: both paths through the diagram send an object (H,φ) to $\alpha\varphi\colon H \to G'$, a 1-cell as in (6) to

$$\begin{array}{ccc} H & \xrightarrow{\sigma} & K, \\ & \overset{\Rightarrow}{\alpha(g)^{-1}} & \\ {\scriptstyle \alpha\varphi}\searrow & & \swarrow{\scriptstyle \alpha\psi} \\ & G' & \end{array}$$

and a 2-cell $\sigma \Rightarrow \sigma'$ represented by k to a 2-cell represented by the same k.

For 2-functoriality it then only remains to show that for any 2-cell $g\colon \alpha \Rightarrow \alpha'$ of maps $G \to G'$ in **Glo** the two pastings

$$\mathfrak{O}^{\mathrm{gl}}_G \underset{\alpha'_!}{\overset{\alpha_!}{\rightrightarrows}}{\scriptstyle \Downarrow g_!}\ \mathfrak{O}^{\mathrm{gl}}_{G'} \xrightarrow{\gamma} \mathbf{Glo}_{/G'} \qquad \text{and} \qquad \mathfrak{O}^{\mathrm{gl}}_G \xrightarrow{\gamma} \mathbf{Glo}_{/G} \underset{\alpha'_!}{\overset{\alpha_!}{\rightrightarrows}}{\scriptstyle \Downarrow g_!}\ \mathbf{Glo}_{/G'}$$

agree pointwise. However, by direct inspection both are given on an object (H,φ) of $\mathfrak{O}^{\mathrm{gl}}_G$ simply as the 1-cell

$$\begin{array}{ccc} H & \xrightarrow{=} & H \\ & \overset{\Rightarrow}{g} & \\ {\scriptstyle \alpha\varphi}\searrow & & \swarrow{\scriptstyle \alpha'\varphi} \\ & G & \end{array}$$

which completes the proof of the lemma. ☐

3.3.3. *Putting the pieces together.* Now we are finally ready to deduce our comparison result:

Proof of Theorem 3.3.2. As mentioned in the beginning of this subsection, we will first construct an equivalence $\underline{\mathscr{S}}^{\mathrm{gl}} \simeq \underline{\mathrm{Spc}}_{\mathrm{Glo}}$ by hand:

Proposition 3.3.13 says that the maps Ψ define a 2-natural transformation between the global categories $\boldsymbol{E\mathcal{M}}$**-•-SSet** and $\mathbf{PSh}(\mathfrak{O}^{\mathrm{gl}}_\bullet)\colon G \mapsto \mathbf{PSh}(\mathfrak{O}^{\mathrm{gl}}_G)$. If we equip $\boldsymbol{E\mathcal{M}}$**-*G*-SSet** with the G-global weak equivalences for varying G and each $\mathbf{PSh}(\mathfrak{O}^{\mathrm{gl}}_G)$ with the levelwise weak homotopy equivalences, this lifts to a map of global relative categories, which in turn decends to an equivalence between the global ∞-categories obtained by pointwise localization according to Proposition 3.3.11. Note that the localization of $\boldsymbol{E\mathcal{M}}$**-•-SSet** is the global ∞-category $\underline{\mathscr{S}}^{\mathrm{gl}}$

by definition; it will now be useful to pick a very specific localization of $\mathbf{PSh}(\mathfrak{O}^{\mathrm{gl}}_\bullet)$ for the purposes of this proof:

Namely, we pick a *simplicially enriched* fibrant replacement functor for the Kan-Quillen model structure (for example via the enriched small object argument [Rie14, Theorem 13.5.2] or simply by using the geometric realization-singular set adjunction), which provides us with an enriched functor $r\colon \mathbf{SSet} \to \mathbf{Kan}$ together with enriched natural transformations $\mathrm{id} \Rightarrow ir$ and $\mathrm{id} \Rightarrow ri$ that are levelwise weak homotopy equivalences, where $i\colon \mathbf{Kan} \hookrightarrow \mathbf{SSet}$ is the inclusion. As an upshot, if A is any simplicially enriched category, then $r \circ -\colon \mathbf{PSh}(A) \to \mathbf{PSh}^{\mathbf{Kan}}(A) := \mathbf{Fun}(A^{\mathrm{op}}, \mathbf{Kan})$ is a homotopy equivalence with respect to the levelwise weak homotopy equivalences, so it induces an equivalence of ∞-categorical localizations. Specializing this to our situation, the maps r assemble into a map of global relative categories from $\mathbf{PSh}(\mathfrak{O}^{\mathrm{gl}}_\bullet)$ to $\mathbf{PSh}^{\mathbf{Kan}}(\mathfrak{O}^{\mathrm{gl}}_\bullet)$. Finally, for any simplicial category A the enriched-natural comparison map

$$\mathrm{N}\big(\mathbf{PSh}^{\mathbf{Kan}}(A)\big) = \mathrm{N}\mathbf{Fun}(A^{\mathrm{op}}, \mathbf{Kan}) \to \mathrm{Fun}(\mathrm{N}_\Delta(A^{\mathrm{op}}), \mathrm{N}_\Delta(\mathbf{Kan})) = \mathrm{PSh}(\mathrm{N}_\Delta A)$$

is a localization at the levelwise weak homotopy equivalences as a consequence of [Lur09, Proposition 4.2.4.4], see also [Len20, Proposition A.1.18], where this argument is spelled out in detail. Thus, we altogether get a map of global ∞-categories

$$\mathrm{N}\big(\mathbf{PSh}(\mathfrak{O}^{\mathrm{gl}}_\bullet)\big) \xrightarrow{r\circ -} \mathrm{N}\big(\mathbf{PSh}^{\mathbf{Kan}}(\mathfrak{O}^{\mathrm{gl}}_\bullet)\big) \xrightarrow{\text{canonical}} \mathrm{PSh}(\mathrm{N}_\Delta(\mathfrak{O}^{\mathrm{gl}}_\bullet))$$

that is pointwise a localization, whence induces an equivalence $\underline{\mathscr{S}}^{\mathrm{gl}} \simeq \mathrm{PSh}(\mathrm{N}_\Delta\mathfrak{O}^{\mathrm{gl}}_\bullet)$ of global ∞-categories.

Restricting along the strictly 2-natural equivalence $\gamma\colon \mathfrak{O}^{\mathrm{gl}}_\bullet \Rightarrow \mathbf{Glo}_{/\bullet}$ of 2-functors $\mathbf{Glo} \to \mathbf{Cat}_\Delta$ (see Lemmas 3.3.15 and 3.3.16) yields an equivalence of global ∞-categories $\mathrm{PSh}(\mathrm{N}_\Delta(\mathbf{Glo}_{/\bullet})) \simeq \mathrm{PSh}(\mathrm{N}_\Delta\mathfrak{O}^{\mathrm{gl}}_\bullet)$. By Proposition A.1 the left hand side is then further equivalent to $\mathrm{PSh}(\mathrm{Glo}_{/\bullet}) = \underline{\mathrm{Spc}}_{\mathrm{Glo}}$. This completes the construction of an equivalence $\underline{\mathrm{Spc}}_{\mathrm{Glo}} \simeq \underline{\mathscr{S}}^{\mathrm{gl}}$ of global ∞-categories.

As $\underline{\mathrm{Spc}}_{\mathrm{Glo}}$ is presentable (Example 2.4.4), so is $\underline{\mathscr{S}}^{\mathrm{gl}}$. Moreover, the universal property of $\underline{\mathrm{Spc}}_{\mathrm{Glo}}$ shows that the equivalence $F\colon \underline{\mathrm{Spc}}_{\mathrm{Glo}} \to \underline{\mathscr{S}}^{\mathrm{gl}}$ constructed above is characterized essentially uniquely by the image of the terminal object $* \in \underline{\mathrm{Spc}}_{\mathrm{Glo}}(1)$, so it only remains to verify that F sends this to the terminal object of $\mathscr{S}^{\mathrm{gl}}$. However, this follows simply from the fact that $F(1)\colon \underline{\mathrm{Spc}}_{\mathrm{Glo}}(1) \to \mathscr{S}^{\mathrm{gl}}$ is an equivalence of ordinary ∞-categories. □

4. Parametrized semiadditivity

The goal of this section is to introduce the parametrized analogue of the familiar notion of semiadditivity of an ∞-category, following the ideas introduced by Nardin [Nar16]. In the parametrized setting, the notion of semiadditivity comes in various flavors, parametrized by suitable subcategories $P \subseteq T$: roughly speaking, a T-∞-category $\mathcal{C}$ is P-semiadditive if it is pointwise semiadditive, admits left adjoints $p_!$ and right adjoints p_* for the morphisms $p\colon A \to B$ in P satisfying base change, and a canonical *norm map* $\mathrm{Nm}_p\colon p_! \to p_*$ between these two adjoints is an equivalence.

4.1. **Pointed T-∞-categories.** As a first step towards defining parametrized semiadditivity, we introduce the notion of pointedness for T-∞-categories. Recall that a *zero object* of an ∞-category is an object which is both initial and terminal. An ∞-category is called *pointed* if it admits a zero object. This has the following parametrized analogue.

Definition 4.1.1. Let $\mathcal{C}$ be a T-∞-category and let $c\colon \underline{1} \to \mathcal{C}$ be a T-∞-functor. We say that c is a *T-zero object* of $\mathcal{C}$ if $c(B) \in \mathcal{C}(B)$ is a zero object for every $B \in T$. We say that $\mathcal{C}$ is *pointed* if it admits a T-zero object; equivalently, $\mathcal{C}(B)$ is a pointed ∞-category for every $B \in T$ and $f^*\colon \mathcal{C}(B) \to \mathcal{C}(A)$ preserves the zero object for every $f\colon A \to B$ in T.

Similarly, we say that $c\colon \underline{1} \to \mathcal{C}$ is a *T-initial object* (resp. a *T-final object*) if $c(B) \in \mathcal{C}(B)$ is an initial object (resp. a final object) for all $B \in T$.

Denote by $\mathrm{Cat}_T^* \subseteq \mathrm{Cat}_T$ the (non-full) subcategory spanned by the T-∞-categories admitting a T-final object and the T-functors that preserve the T-final object. We let $\mathrm{Cat}_T^{\mathrm{pt}} \subseteq \mathrm{Cat}_T^*$ denote the full subcategory spanned by the pointed T-∞-categories.

Definition 4.1.2. For T-∞-categories $\mathcal{C}$ and $\mathcal{D}$ which admit a T-final object, we let

$$\underline{\mathrm{Fun}}_T^*(\mathcal{C}, \mathcal{D}) \subseteq \underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D})$$

be the full parametrized subcategory spanned at $B \in T$ by the *pointed $T_{/B}$-functors*, i.e. those $F\colon \pi_B^* \mathcal{C} \to \pi_B^* \mathcal{D}$ which preserve the $T_{/B}$-final object.

In the non-parametrized setting, an ∞-category is pointed if and only if it admits an initial object $\emptyset$ and a terminal object 1, and the canonical map $\emptyset \to 1$ is an equivalence. In other words: the limit and colimit of the empty diagram in $\mathcal{C}$ exist and are canonically equivalent. For our discussion of parametrized semiadditivity, we will need an enhancement of this statement to the parametrized setting which identifies more generally the (parametrized) limit and colimit corresponding to a *disjoint summand inclusion.*

Definition 4.1.3. A map $f\colon A \to B$ in an ∞-category $\mathcal{E}$ is called a *disjoint summand inclusion* if there exists another morphism $g\colon C \to B$ in $\mathcal{E}$ such that the maps f and g exhibit B as a coproduct of A and C in $\mathcal{E}$.

Lemma 4.1.4. *Let $\mathcal{C}$ be a T-∞-category and let $f\colon A \to B$ be a disjoint summand inclusion in* $\mathrm{PSh}(T)$.

(1) If $\mathcal{C}$ admits a T-initial object, then the restriction functor $f^*\colon \mathcal{C}(B) \to \mathcal{C}(A)$ admits a fully faithful left adjoint $f_!\colon \mathcal{C}(A) \to \mathcal{C}(B)$;
(2) If $\mathcal{C}$ admits a T-final object, then the restriction functor $f^*\colon \mathcal{C}(B) \to \mathcal{C}(A)$ admits a fully faithful right adjoint $f_*\colon \mathcal{C}(A) \to \mathcal{C}(B)$;
(3) If $\mathcal{C}$ admits both a T-initial object and a T-final object, then there is a unique map

$$\mathrm{Nm}_f\colon f_! \implies f_*$$

whose restriction $f^* \mathrm{Nm}_f\colon f^*f_! \Rightarrow f^*f_*$ is the equivalence inverse to the composite

$$f^*f_* \xrightarrow[\sim]{c_f^*} \mathrm{id} \xrightarrow[\sim]{u_f^!} f^*f_!;$$

(4) If $\mathcal{C}$ is pointed, this map $\mathrm{Nm}_f\colon f_! \Rightarrow f_*$ is an equivalence.

Proof. Let $g\colon C \to B$ denote the disjoint complement of f. As $\mathcal{C}\colon \mathrm{PSh}(T)^{\mathrm{op}} \to \mathrm{Cat}_\infty$ sends colimits in $\mathrm{PSh}(T)$ to limits of ∞-categories, the maps f and g induce an equivalence

$$(f^*, g^*)\colon \mathcal{C}(B) \xrightarrow{\simeq} \mathcal{C}(A) \times \mathcal{C}(C),$$

and under this equivalence the restriction functor $f^*\colon \mathcal{C}(B) \to \mathcal{C}(A)$ corresponds to the first projection map $\mathcal{C}(A) \times \mathcal{C}(C) \to \mathcal{C}(A)$. If $\mathcal{C}$ admits a T-initial object, then this projection has a fully faithful left adjoint given by $X \mapsto (X, \emptyset)$, where $\emptyset \in \mathcal{C}(C)$ denotes the initial object. It follows that f^* admits a fully faithful left adjoint $f_!$. Similarly if $\mathcal{C}$ admits a T-final object, the projection has a fully faithful right adjoint given by $X \mapsto (X, 1)$, where $1 \in \mathcal{C}(C)$ is a final object, and thus f^* admits a right adjoint f_*. If $\mathcal{C}$ satisfies both, then inserting the unique map $\emptyset \to 1$ in the second variable gives rise to a natural transformation $\mathrm{Nm}_f\colon f_! \Rightarrow f_*$, which is uniquely determined by requiring that its restriction along f is the canonical identification $f^*f_! \simeq f^*f_*$ in (3). It is clear that Nm_f is an equivalence whenever $\mathcal{C}(C)$ is pointed. □

Before moving on, we record a useful characterization of the disjoint summand inclusions in a presheaf category:

Lemma 4.1.5. *Let $f\colon X \to Y$ be a map in $\mathrm{PSh}(T)$. Then the following are equivalent:*

(1) The map f is a disjoint summand inclusion;
(2) For every map $t\colon A \to Y$ from a representable object $A \in T$, the base change $t^*f\colon A \times_Y X \to A$ of f is a disjoint summand inclusion (i.e. either t^*f is an equivalence or $A \times_Y X = \emptyset$).

Proof. It is clear that (1) implies (2) as disjoint summand inclusions in $\mathrm{PSh}(T)$ are closed under pullback. We thus assume that (2) is satisfied and prove that it implies (1).

By the co-Yoneda Lemma, there are equivalences $X \simeq \mathrm{colim}_{A \in T_{/X}} A$ and $Y \simeq \mathrm{colim}_{B \in T_{/Y}} B$. Under these equivalences, the map f corresponds to restriction of indexing diagrams along the functor $T_{/f}\colon T_{/X} \to T_{/Y}$. It will therefore suffice to show that this functor is a disjoint summand inclusion of ∞-categories, or equivalently that it is fully faithful and any object of $T_{/X}$ admitting a map to or from the image of $T_{/f}$ already belongs to the essential image.

For this, we will first show that f is a monomorphism. This will immediately imply that $\mathrm{PSh}(T)_{/f}$ is fully faithful, hence so is $T_{/f}$. To this end, we observe that the natural map $\tau\colon \coprod_{A \in T_{/X}} A \to \mathrm{colim}_{A \in T_{/X}} A \simeq X$ is an effective epimorphism [ABFJ22, Example 2.3.6], so pullbacks along it detect monomorphisms by [Lur09, Proposition 6.2.3.17]. However, by universality of colimits, τ^*f is simply given as the coproduct of all the pullbacks of f along all the maps $A \to X$, and each of these is in particular a monomorphism by assumption.

For the closure of the image, consider objects $t\colon A \to X$ in $T_{/X}$ and $u\colon B \to Y$ in $T_{/Y}$. If there is a map $\alpha\colon u \to T_{/f}(t)$ in $T_{/Y}$, then $ft\alpha \sim u$, so $t\alpha$ is a preimage of

u. Conversely, a map $\beta\colon T_{/f}(t) \to u$ amounts to a commutative square

$$\begin{array}{ccc} A & \xrightarrow{\beta} & B \\ {\scriptstyle t}\downarrow & & \downarrow{\scriptstyle u} \\ X & \xrightarrow[f]{} & Y \end{array} \tag{7}$$

in $\mathrm{PSh}(T)$. By assumption, the pullback $B \times_Y X$ is either empty or the projection to B is an equivalence. However, the first case is impossible as $B \times_Y X$ receives a map from A induced by (7), so we see there exists a (pullback) square of the form

$$\begin{array}{ccc} B & = & B \\ {\scriptstyle v}\downarrow & \lrcorner & \downarrow{\scriptstyle u} \\ X & \xrightarrow[f]{} & Y. \end{array}$$

The map v is the desired preimage of u, finishing the proof of the lemma. □

Given a T-∞-category $\mathcal{C}$ admitting a T-final object, one may form the T-∞-category $\mathcal{C}_*$ of pointed objects of $\mathcal{C}$. We will need several basic properties of this construction.

Construction 4.1.6. Let $\mathcal{C}$ be a T-∞-category which admits a T-final object. We define the T-∞-category $\mathcal{C}_*$ of *pointed objects of* $\mathcal{C}$ as the composite

$$T^{\mathrm{op}} \xrightarrow{\mathcal{C}} \mathrm{Cat}^*_\infty \xrightarrow{(-)_*} \mathrm{Cat}^{\mathrm{pt}}_\infty,$$

where the second functor sends an ∞-category $\mathcal{E}$ with terminal object $*$ to the slice $\mathcal{E}_* := \mathcal{E}_{*/}$. This construction is functorial in $\mathcal{C}$ and assembles into a functor $(-)_*\colon \mathrm{Cat}^*_T \to \mathrm{Cat}^{\mathrm{pt}}_T$.

Corollary 4.1.7. *The functor* $(-)_*\colon \mathrm{Cat}^*_T \to \mathrm{Cat}^{\mathrm{pt}}_T$ *is right adjoint to the fully faithful inclusion* $\mathrm{Cat}^{\mathrm{pt}}_T \hookrightarrow \mathrm{Cat}^*_T$.

Proof. This is immediate from the fact that the functor $(-)_*\colon \mathrm{Cat}^*_\infty \to \mathrm{Cat}^{\mathrm{pt}}_\infty$ is right adjoint to the fully faithful inclusion $\mathrm{Cat}^{\mathrm{pt}}_\infty \subseteq \mathrm{Cat}^*_\infty$. □

Corollary 4.1.8. *For* $\mathcal{C} \in \mathrm{Cat}^{\mathrm{pt}}_T$ *and* $\mathcal{D} \in \mathrm{Cat}^*_T$, *composition with the adjunction counit* $\mathcal{D}_* \to \mathcal{D}$ *induces an equivalence of T-∞-categories* $\underline{\mathrm{Fun}}^*_T(\mathcal{C}, \mathcal{D}_*) \xrightarrow{\sim} \underline{\mathrm{Fun}}^*_T(\mathcal{C}, \mathcal{D})$.

Proof. We will prove that the induced functor $\mathrm{Fun}^*_T(\mathcal{C}, \mathcal{D}_*) \to \mathrm{Fun}^*_T(\mathcal{C}, \mathcal{D})$ on underlying ∞-categories is an equivalence. For every $B \in T$ this thus gives an equivalence $\mathrm{Fun}^*_{T/B}(\pi^*_B\,\mathcal{C}, \pi^*_B\,\mathcal{D}_*) \to \mathrm{Fun}^*_{T/B}(\pi^*_B\,\mathcal{C}, \pi^*_B\,\mathcal{D})$ which proves the claim. By the Yoneda lemma it suffices to prove that for any ∞-category $\mathcal{E}$ the above map induces an equivalence

$$\mathrm{Hom}_{\mathrm{Cat}_\infty}(\mathcal{E}, \mathrm{Fun}^*_T(\mathcal{C}, \mathcal{D}_*)) \to \mathrm{Hom}_{\mathrm{Cat}_\infty}(\mathcal{E}, \mathrm{Fun}^*_T(\mathcal{C}, \mathcal{D})).$$

Observe that the cotensor $\mathcal{D}^{\mathcal{E}}$ of $\mathcal{D}$ by $\mathcal{E}$ again has fiberwise final objects, and that there is a canonical equivalence $(\mathcal{D}^{\mathcal{E}})_* \simeq (\mathcal{D}_*)^{\mathcal{E}}$. The cotensoring adjunction gives rise to an equivalence

$$\mathrm{Hom}_{\mathrm{Cat}_\infty}(\mathcal{E}, \mathrm{Fun}^*_T(\mathcal{C}, \mathcal{D})) \simeq \mathrm{Hom}_{\mathrm{Cat}^*_T}(\mathcal{C}, \mathcal{D}^{\mathcal{E}})$$

and similarly for $\mathcal{D}_*$. It thus suffices to show that for every ∞-category $\mathcal{E}$ the map $(\mathcal{D}^{\mathcal{E}})_* \to \mathcal{D}^{\mathcal{E}}$ induces an equivalence

$$\mathrm{Hom}_{\mathrm{Cat}^*_T}(\mathcal{C}, (\mathcal{D}^{\mathcal{E}})_*) \to \mathrm{Hom}_{\mathrm{Cat}^*_T}(\mathcal{C}, \mathcal{D}^{\mathcal{E}}),$$

which is true by the adjunction of Corollary 4.1.7. □

It follows that the condition of being pointed is closed under passing to parametrized functor categories.

Corollary 4.1.9. *Consider T-∞-categories $\mathcal{C}$ and $\mathcal{D}$ admitting a T-final object. If either $\mathcal{C}$ or $\mathcal{D}$ is pointed, the T-∞-category $\underline{\mathrm{Fun}}^*_T(\mathcal{C}, \mathcal{D})$ is pointed as well.*

Proof. The case where $\mathcal{D}$ is pointed is clear from Proposition 2.3.24. When $\mathcal{C}$ is pointed, we have by Corollary 4.1.8 an equivalence $\underline{\mathrm{Fun}}^*_T(\mathcal{C}, \mathcal{D}_*) \xrightarrow{\simeq} \underline{\mathrm{Fun}}^*_T(\mathcal{C}, \mathcal{D})$, which reduces to the previous case since $\mathcal{D}_*$ is pointed. □

Lemma 4.1.10. *Let $\mathbf{U}$ be a class of T-∞-groupoids and let $\mathcal{D}$ be a $\mathbf{U}$-complete T-∞-category admitting a T-final object. Then $\mathcal{D}_*$ is also $\mathbf{U}$-complete and the forgetful functor $\mathcal{D}_* \to \mathcal{D}$ preserves $\mathbf{U}$-limits.*

Proof. Let $B \in T$ and let $(f\colon A \to B) \in \mathbf{U}(B)$. Consider objects $X \in \mathcal{D}(B)$ and $Y \in \mathcal{D}(A)_*$, and assume we are given a map $\varphi\colon f^*X \to Y$ in $\mathcal{D}(A)$ which exhibits X as a right adjoint object to Y under $f^*\colon \mathcal{D}(B) \to \mathcal{D}(A)$, in the sense that for all $Z \in \mathcal{C}(B)$ the composite

$$\mathrm{Hom}_{\mathcal{C}(B)}(Z, X) \xrightarrow{f^*} \mathrm{Hom}_{\mathcal{C}(A)}(f^*Z, f^*X) \xrightarrow{\varphi\circ -} \mathrm{Hom}_{\mathcal{C}(A)}(f^*Z, Y)$$

is an equivalence. Taking $Z = *$ gives X a canonical basepoint which turns the map $f^*X \to Y$ into a map in $\mathcal{D}(A)_*$. One now observes that this map exhibits $X \in \mathcal{D}(A)_*$ as a right adjoint object to $Y \in \mathcal{D}(B)_*$ under $f^*\colon \mathcal{D}(B)_* \to \mathcal{D}(A)_*$. This proves the claim. □

4.2. **Orbital subcategories.** In order to obtain a parametrized analogue of semi-additivity, we first need a parametrized analogue of the notion of *finite (co)products*. In the non-parametrized setting, an ∞-category $\mathcal{E}$ admits finite (co)products if and only if it admits (co)limits indexed by finite sets (regarded as discrete ∞-categories). To generalize this to the parametrized setting, we would thus need a parametrized analogue of the notion of finite set.

In general, there might be various natural choices for such a generalization. A large family of examples comes from certain subcategories P of T that we call *orbital*, extending the terminology of [BDG+16]. To every orbital subcategory P, we assign a class of T-∞-groupoids called the *finite P-sets*, and a T-∞-category $\mathcal{C}$ is said to admit *finite P-coproducts* if it admits parametrized colimits indexed by finite P-sets.

Definition 4.2.1. Let $\mathbb{F}_T$ be the finite coproduct completion of T, defined as the full subcategory of $\mathrm{PSh}(T)$ spanned by the finite disjoint unions $\coprod_{i=1}^n A_i$ of representable presheaves $A_i \in T$. We refer to $\mathbb{F}_T$ as the *∞-category of finite T-sets*.

For a wide subcategory $P \subseteq T$, we let $\mathbb{F}_T^P \subseteq \mathbb{F}_T$ denote the wide subcategory spanned by all the morphisms which are a disjoint union of morphisms of the form

$(p_i)\colon \bigsqcup_{i=1}^n A_i \to B$ where each morphism $p_i\colon A_i \to B$ is in P. We refer to $\mathbb{F}_T^P$ as the *∞-category of finite P-sets.*

Note that $\mathbb{F}_T^P$ is equivalent to the finite coproduct completion of the ∞-category P.

Definition 4.2.2. A wide subcategory $P \subseteq T$ is called *orbital* if the base change of a morphism in $\mathbb{F}_T^P$ along an arbitrary morphism in $\mathbb{F}_T$ exists and is again in $\mathbb{F}_T^P$. Equivalently, for every pullback diagram

$$\begin{array}{ccc} A' & \xrightarrow{\alpha} & A \\ {\scriptstyle p'}\downarrow & \lrcorner & \downarrow{\scriptstyle p} \\ B' & \xrightarrow{\beta} & B \end{array}$$

in $\mathrm{PSh}(T)$, with $A, B, B' \in T$ and $p\colon A \to B$ in P, the morphism $p'\colon A' \to B'$ can be decomposed as a disjoint union $(p_i)_{i=1}^n\colon \bigsqcup_{i=1}^n A_i \to B'$ for morphisms $p_i\colon A_i \to B'$ in P.

The ∞-category T is called *orbital* if it is orbital when regarded as a subcategory of itself.

Remark 4.2.3. An ∞-category T is orbital in our sense if and only if it is orbital in the sense of [BDG+16], [Sha21], [Nar16, Definition 4.1].

Example 4.2.4. Every ∞-category T has a minimal orbital subcategory given by ιT, the core of T.

The following is the main example of an orbital subcategory in this article.

Example 4.2.5. We define $\mathrm{Orb} \subset \mathrm{Glo}$ to be the subcategory spanned by all objects and the injective group homomorphisms. We claim that Orb is an orbital subcategory of Glo. Observe that the ∞-category of finite Glo-sets is equivalent to the $(2,1)$-category of finite groupoids, which admits all homotopy-pullbacks. The subcategory of finite Orb-sets is the wide subcategory on the faithful maps of groupoids, and thus the orbitality of Orb is equivalent to the observation that pullbacks of faithful maps of groupoids are again faithful.

The following two examples are variations of Example 4.2.5.

Example 4.2.6. The orbit category Orb_G of a finite group G is orbital. More generally, for a Lie group G, let $\mathrm{Orb}_G^{f.i.}$ be the wide subcategory of the orbit ∞-category Orb_G spanned by the morphisms equivalent to projections $G/K \to G/H$ for subgroups $K \subseteq H \subseteq G$ where K has finite index in H. Then $\mathrm{Orb}_G^{f.i.}$ is an orbital subcategory of Orb_G. Indeed, the pullback of $G/K \to G/H$ along a morphism $G/H' \to G/H$ is computed via a double coset formula, namely the finite disjoint union $\bigsqcup_{[g]\in H'\backslash H/K} G/(H' \cap {}^gK)$.

Example 4.2.7. Mixing Example 4.2.5 with Example 4.2.6, one can define an ∞-category $\mathrm{Glo}_{\mathrm{Lie}}$ whose objects are compact Lie groups G and whose morphism space $\mathrm{Hom}_{\mathrm{Glo}}(G, H)$ is given by the homotopy orbit space $\mathrm{Hom}_{\mathrm{TopGrp}}(G, H)_{hH}$, where H acts on the space of continuous homomorphisms $G \to H$ via conjugation. See [GH07, Section 4.1] or [Rez14, Section 2.2]. Let $\mathrm{Orb}_{\mathrm{Lie}}^{f.i.} \subseteq \mathrm{Glo}_{\mathrm{Lie}}$ be the wide subcategory whose morphisms are given by the injective homomorphisms $G \hookrightarrow H$ of finite index. Then $\mathrm{Orb}_{\mathrm{Lie}}^{f.i.}$ is an orbital subcategory. The relevant pullbacks are again computed by a double coset formula.

Orbital subcategories are closed under various constructions:

Example 4.2.8. (1) (Slice) Let $P \subseteq T$ be an orbital subcategory and let $B \in T$ be an object. Then the wide subcategory of $T_{/B}$ spanned by those morphisms over B contained in P is again an orbital subcategory. We will often abuse notation and denote this subcategory again by P.

(2) (Preimage) More generally, if $f\colon S \to T$ is a right fibration, then the preimage $Q := f^{-1}(P) \subseteq S$ of an orbital subcategory $P \subseteq T$ is again orbital. Indeed, note that $\mathbb{F}_Q = f^{-1}(\mathbb{F}_P)$, and that the extension $\mathbb{F}_Q \to \mathbb{F}_P$ of f is still a right fibration. The claim is then an instance of [HHLN22b, Proposition 2.6].

(3) (Intersection) The intersection $\bigcap_{i\in I} P_i$ of any non-empty collection of orbital subcategories $P_i \subseteq T$ is again orbital.

Example 4.2.9. Let G be a finite group. Combining part (2) from Example 4.2.8 with Example 4.2.6, we find that for a G-space $X\colon \mathrm{Orb}_G^{\mathrm{op}} \to \mathrm{Spc}$, the ∞-category $\int X$ of points of X (that is, the total category of the right fibration classified by X) is orbital.

So far, all the given examples of orbital subcategories are equivariant in nature, being a variation of the orbit category of a group; these are the examples we are most interested in in this article. In the following example we mention some orbital subcategories that appear in completely different contexts.

Example 4.2.10. Let T be an ∞-category, and assume $P \subseteq T$ is a wide subcategory such that base changes of morphisms in P exist in T and are again in P. Then P is orbital.

In particular, many geometric examples give rise to orbital subcategories. For example:

(1) If $T = \mathrm{Diff}$ is the ordinary category of smooth manifolds, the wide subcategory on the local diffeomorphisms is orbital.
(2) If $T = \mathrm{Sm}_S$ is the ordinary category of smooth schemes over some base scheme S, the wide subcategory on the étale morphisms is orbital.

For the remainder of this subsection, we will fix an orbital subcategory $P \subseteq T$.

Definition 4.2.11. We define the *T-∞-category of finite P-sets* $\underline{\mathbb{F}}_T^P$. Given $B \in T$, we let

$$\underline{\mathbb{F}}_T^P(B) \subseteq \mathrm{PSh}(T)_{/B}$$

be the full subcategory spanned by those morphisms $p\colon A \to B$ in $\mathrm{PSh}(B)$ which can be decomposed as a coproduct $(p_i)\colon \bigsqcup_{i=1}^n A_i \to B$ such that each morphism $p_i\colon A_i \to B$ is in P. By orbitality of P, $\underline{\mathbb{F}}_T^P$ forms a parametrized subcategory of $\underline{\mathrm{Spc}}_T$. When $P = T$, we simply write $\underline{\mathbb{F}}_T$ for $\underline{\mathbb{F}}_T^T$.

Since $\underline{\mathbb{F}}_T^P$ forms a class of T-∞-groupoids (see Definition 2.3.12) it makes sense to speak of parametrized colimits indexed by $\underline{\mathbb{F}}_T^P$.

Definition 4.2.12. Let $P \subseteq T$ be an orbital subcategory of T. We say that a T-∞-category $\mathcal{C}$ *admits finite P-coproducts* if it admits $\underline{\mathbb{F}}_T^P$-colimits, in the sense of Definition 2.3.8. Dually, we say $\mathcal{C}$ *admits finite P-products* if it admits $\underline{\mathbb{F}}_T^P$-limits.

Definition 4.2.13. Let $\mathcal{C}$ and $\mathcal{D}$ be two T-∞-categories which admit $\underline{\mathbb{F}}_T^P$-limits. We define $\underline{\mathrm{Fun}}^{P\text{-}\times}(\mathcal{C},\mathcal{D})$ to be the full parametrized subcategory of $\underline{\mathrm{Fun}}(\mathcal{C},\mathcal{D})$ spanned in level B by the $T_{/B}$-functors $F\colon \pi_B^*\,\mathcal{C} \to \pi_B^*\,\mathcal{D}$ which preserve P-products (i.e. preserves $\pi_B^{-1}(P)$-products, c.f. Example 4.2.8). Dually we define $\underline{\mathrm{Fun}}^{P\text{-}\sqcup}(\mathcal{C},\mathcal{D})$.

When $P = T$, a T-∞-category $\mathcal{C}$ admits finite T-coproducts in the sense of Definition 4.2.12 if and only if it has finite T-coproducts in the sense of Shah [Sha21, Definition 5.10].

The following result gives a more explicit characterization of the condition for a T-∞-category to admit finite P-(co)products.

Proposition 4.2.14 (cf. [Sha21, Proposition 5.12], [Nar16, Proposition 2.11])**.** *Let $P \subseteq T$ be an orbital subcategory and let $\mathcal{C}$ be a T-∞-category. Then $\mathcal{C}$ admits finite P-coproducts if and only if the following two conditions hold:*

(1) $\mathcal{C}$ admits fiberwise finite coproducts, see Definition 2.3.11;
(2) for every morphism $p\colon A \to B$ in P, the restriction functor $p^*\colon \mathcal{C}(B) \to \mathcal{C}(A)$ admits a left adjoint $p_!\colon \mathcal{C}(A) \to \mathcal{C}(B)$ and for every pullback square as in Lemma 2.3.14(2) with $A, B, B' \in T$ and $f\colon A \to B$ in P, the Beck-Chevalley transformation $p'_! \circ \alpha^* \Rightarrow \beta^* \circ p_!$ is an equivalence.

Dually, $\mathcal{C}$ admits finite P-products if and only the dual conditions hold.

Proof. By definition, every morphism in $\mathbb{F}_T^P$ with target $B \in T$ can be written as a composite

$$\bigsqcup_{i=1}^n B_i \xrightarrow{\bigsqcup_{i=1}^n p_i} \bigsqcup_{i=1}^n B \xrightarrow{\nabla} B \tag{8}$$

for morphisms $p_i\colon B_i \to B$ in P, where $\nabla\colon \bigsqcup_{i=1}^n B \to B$ denotes the fold map in $\mathrm{PSh}(T)$. As the functor $\mathcal{C}\colon\ \mathrm{PSh}(T)^{\mathrm{op}} \to \mathrm{Cat}_\infty$ sends colimits in $\mathrm{PSh}(T)$ to limits of ∞-categories, the condition of left $\mathbb{F}_T^P$-adjointability splits up as left adjointability for the maps $\nabla\colon \bigsqcup_{i=1}^n B \xrightarrow{\nabla} B$ and left adjointability for the maps in P. Spelling out the definitions, one observes that the former is equivalent to condition (1) while the latter is equivalent to condition (2). □

A similar argument gives the following analogous result for preservation of finite P-coproducts:

Proposition 4.2.15. *Let $P \subseteq T$ be an orbital subcategory and let $\mathcal{C}$ and $\mathcal{D}$ be T-∞-categories that admits finite P-coproducts. Then a T-functor $F\colon \mathcal{C} \to \mathcal{D}$ preserves finite P-coproducts if and only if it preserves fiberwise finite coproducts and for every morphism $p\colon A \to B$ in P, the Beck-Chevalley transformation $p_! \circ F_A \Rightarrow F_B \circ p_!$ is an equivalence.*

The dual statement for preservation of finite P-products also holds. □

We end this subsection by showing that the T-∞-category $\underline{\mathbb{F}}_T^P$ can be characterized by a universal property: it is the free T-∞-category admitting finite P-coproducts.

Corollary 4.2.16. *The T-∞-category $\underline{\mathbb{F}}_T^P$ admits finite P-coproducts and the inclusion $\underline{\mathbb{F}}_T^P \hookrightarrow \underline{\mathrm{Spc}}_T$ preserves finite P-coproducts.*

Proof. By Example 2.3.20 it suffices to show that the subcategory $\underline{\mathbb{F}}_T^P \hookrightarrow \underline{\mathrm{Spc}}_T$ is closed under finite P-coproducts. But this is clear from Proposition 4.2.14 since it is closed under fiberwise coproducts and under composition with morphisms in P by construction. □

Corollary 4.2.17. *Let $\mathcal{D}$ be a T-∞-category admitting finite P-coproducts. Let $*\colon \underline{1} \to \underline{\mathbb{F}}_T^P$ denote the T-final object, given at $B \in T$ by the identity $\mathrm{id}_B \in \underline{\mathbb{F}}_T^P(B)$. Then composition with $*\colon \underline{1} \to \underline{\mathbb{F}}_T^P$ induces an equivalence of T-∞-categories*

$$\underline{\mathrm{Fun}}_T^{P\text{-}\sqcup}(\underline{\mathbb{F}}_T^P, \mathcal{D}) \to \underline{\mathrm{Fun}}_T(\underline{1}, \mathcal{D}) \simeq \mathcal{D}\,.$$

Proof. It follows directly from Corollary 4.2.16 that the subcategory $\underline{\mathbb{F}}_T^P \subseteq \underline{\mathrm{Spc}}_T$ is the smallest subcategory which contains the T-final object and is closed under finite P-coproducts, meaning it is equivalent to $\underline{\mathrm{PSh}}_T^{\mathbb{F}_T^P}(\underline{1})$ in the notation of [MW21, Definition 6.1.6]. The claim is then an instance of [MW21, Theorem 6.1.10]. □

4.3. **Atomic orbital subcategories and norm maps.** Let P be an orbital subcategory of T. In this subsection, we will define what it means for P to be an *atomic orbital* subcategory of T, generalizing a definition of [Nar16]. The atomicity condition on P will allow us to define *norm maps* $\mathrm{Nm}_p\colon p_! \to p_*$ in a pointed T-∞-category $\mathcal{C}$, making it possible to compare finite P-coproducts in $\mathcal{C}$ to finite P-products in $\mathcal{C}$. We may therefore think of the atomic orbital subcategories as classifying the various potential 'levels of semiadditivity' that a T-∞-category might have.

Definition 4.3.1. Suppose T is an ∞-category and let $P \subseteq T$ be an orbital subcategory. We say that P is *atomic orbital* if for every morphism $p\colon A \to B$ in P the diagonal $\Delta\colon A \to A \times_B A$ in $\mathrm{PSh}(T)$ is a disjoint summand inclusion in the sense of Definition 4.1.3. An ∞-category T is called *atomic orbital* if it is atomic orbital as a subcategory of itself.

For a subcategory $P \subset T$, being an atomic orbital subcategory is a very restrictive condition: since every disjoint summand inclusion in $\mathrm{PSh}(T)$ is in particular a monomorphism, it implies that all the morphisms in P have to be 0-truncated.

The following lemma provides an alternative characterization of atomic subcategories in terms of the triviality of certain retracts. The case $P = T$ of this lemma immediately implies that our definition of atomic orbital ∞-categories is equivalent to that of [Nar16, Definition 4.1].

Lemma 4.3.2. *Let $P \subseteq T$ be an orbital subcategory. Then P is atomic orbital if and only if any morphism $p\colon A \to B$ in P which admits a section in T is an equivalence.*

Proof. Assume first that P is atomic orbital. Let $p\colon A \to B$ be a morphism in P and assume that p admits a section $s\colon B \to A$ in T. We will show that p is an equivalence with inverse s. Since we are given an equivalence $ps \simeq \mathrm{id}_B$, it remains to show that $sp \simeq \mathrm{id}_A$. Equivalently, we may show that the map $(\mathrm{id}_A, sp)\colon A \to A \times_B A$ factors through the diagonal $\Delta_p\colon A \to A \times_B A$. By assumption this diagonal is equivalent to an inclusion $A \hookrightarrow A \sqcup C$ for some presheaf $C \in \mathrm{PSh}(T)$, and since A is a representable presheaf it follows that the map $(\mathrm{id}_A, sp)\colon A \to A \times_B A \simeq A \sqcup C$ must either factor through $\Delta_p\colon A \hookrightarrow A \sqcup C$ or through $C \hookrightarrow A \sqcup C$. Assume for contradiction that we are in the latter situation. Then the pullback of $\Delta_p \colon A \to A \times_B A$ and $(\mathrm{id}_A, sp) \colon A \to A \times_B A$ is the empty presheaf. But this pullback is also equivalent to B, by the following pullback diagram:

$$\begin{array}{ccccc}
B & \xrightarrow{s} & A & \xrightarrow{p} & B \\
{\scriptstyle s}\downarrow & \lrcorner & \downarrow{\scriptstyle (\mathrm{id}_A, sp)} & \lrcorner & \downarrow{\scriptstyle s} \\
A & \xrightarrow{\Delta_p} & A \times_B A & \xrightarrow{\mathrm{pr}_2} & A \\
 & & {\scriptstyle \mathrm{pr}_1}\downarrow & \lrcorner & \downarrow{\scriptstyle p} \\
 & & A & \xrightarrow{p} & B.
\end{array}$$

Since B is not the empty presheaf, this leads to a contradiction, showing that $(\mathrm{id}_A, sp) \colon A \to A \times_B A$ factors through Δ_p as desired.

Conversely, assume that any map in P which admits a section in T is an equivalence. Let $p \colon A \to B$ be a morphism in P. Since P is orbital, the projection map $\mathrm{pr}_1 \colon A \times_B A \to A$ in $\mathrm{PSh}(T)$ can be decomposed as a disjoint union $(p_i)_{i=1}^n \colon \bigsqcup_{i=1}^n A_i \to A$ of morphisms $p_i \colon A_i \to B$ in P. Since A is representable, the diagonal $\Delta_p \colon A \to A \times_B A \simeq \bigsqcup_{i=1}^n A_i$ has to factor through one of the inclusions $A_i \hookrightarrow A \times_B A$, so that the morphism $p_i \colon A_i \to A$ admits a section $A \to A_i$ in T. By the assumption on P, this means that p_i is an equivalence. It follows that the diagonal Δ_p of p is the inclusion of a disjoint summand $A \simeq A_i \hookrightarrow \bigsqcup_{i=1}^n A_i$, as desired. □

Example 4.3.3. Recall the subcategory $\mathrm{Orb} \subset \mathrm{Glo}$ spanned by the injective homomorphisms. Clearly, any injective homomorphism that admits a section is also surjective, hence an isomorphism. Together with Example 4.2.5, we conclude that Orb is an atomic orbital subcategory of Glo. By direct computation one sees that the diagonal in PSh(Glo) of a non-injective group homomorphism is never a disjoint summand inclusion, and thus it follows that Orb is in fact the *maximal* atomic orbital subcategory of Glo.

Remark 4.3.4. There is a classification of the atomic orbital subcategories of Glo in terms of *global transfer systems* in the sense of Barrero [Bar23]. Recall from *op. cit.* that a global transfer system (for the family of finite groups) is a partial order $\leqslant_T$ on the collection of finite groups which refines the subgroup relation and which is closed under preimages, meaning that for a group homomorphism $\alpha \colon G' \to G$, if $H \leqslant_T G$ then $\alpha^{-1}(H) \leqslant G'$. We may assign to $\leqslant_T$ a wide subcategory $\mathrm{Orb}_T \subseteq \mathrm{Orb}$ which contains those injections $i \colon H \hookrightarrow G$ for which $i(H) \leqslant_T G$. It is not difficult to show that Orb_T is an atomic orbital subcategory of Glo, and that conversely every atomic orbital subcategory of Glo is of the form Orb_T for some global transfer system $\leq_T$.

A convenient feature of atomic orbital subcategories is that they are *left cancellable*, in the sense that for morphisms $f \colon A \to B$ and $g \colon B \to C$ in T, if both g and gf are in P then also f is in P.

Lemma 4.3.5. *Every atomic orbital subcategory $P \subseteq T$ is left cancellable.*

Proof. Let $f \colon A \to B$ and $g \colon B \to C$ be morphisms in T, and assume that both g and gf are in P. We will show that then also f is in P. This is a classical argument [Gro60, Remarque 5.5.12]: we may factor f as a composite

$$A \xrightarrow{(1,f)} A \times_C B \xrightarrow{\mathrm{pr}_B} B$$

in $\mathbb{F}_T$, and it will suffice to show that both of these morphisms are morphisms in $\mathbb{F}_T^P$. The projection $\mathrm{pr}_B\colon A\times_C B\to B$ is the base change of $gf\colon A\to C$ along $B\to C$, so it is in $\mathbb{F}_T^P$ by orbitality of P and the assumption on gf. In turn, the morphism $(1,f)\colon A\to A\times_C B$ is a base change of the diagonal map $\Delta_g\colon B\to B\times_C B$, which is by assumption a disjoint summand inclusion and thus in particular in $\mathbb{F}_T^P$. This finishes the proof. ☐

Corollary 4.3.6. *Let $P\subseteq T$ be an atomic orbital subcategory. Then for every $B\in T$, the inclusion $P_{/B}\hookrightarrow T_{/B}$ is fully faithful. In particular, there is an equivalence $\underline{\mathbb{F}}_T^P(B)\simeq(\mathbb{F}_T^P)_{/B}$.* ☐

While atomicity a priori only requires the diagonals of maps in P be disjoint summand inclusions, the next proposition shows that this in fact holds for a more general class of maps in $\mathrm{PSh}(T)$. Recall from Remark 2.3.15 that, given a presheaf B on T, we write $\underline{\mathbb{F}}_T^P(B)\subseteq\mathrm{PSh}(T)_{/B}$ for the full subcategory containing those morphisms $p\colon A\to B$ of presheaves whose base change to any representable $B'\in T$ lives in $\mathbb{F}_T^P$.

Proposition 4.3.7. *Let $P\subseteq T$ atomic orbital, let $Y\in\mathrm{PSh}(T)$ and let $(p\colon X\to Y)\in\underline{\mathbb{F}}_T^P(Y)$. Then the diagonal $\Delta_p\colon X\to X\times_Y X$ in $\mathrm{PSh}(T)$ is a disjoint summand inclusion.*

Proof. By Lemma 4.1.5, it will suffice to show that the base change of $\Delta_p\colon X\to X\times_Y X$ along any map $\alpha=(\alpha_1,\alpha_2)\colon A\to X\times_Y X$ from a representable $A\in T$ is a disjoint summand inclusion. Observe that the map α factors as the following composite:

$$A\xrightarrow{(\mathrm{id},\alpha_2)}A\times_Y X\xrightarrow{\alpha_1\times\mathrm{id}}X\times_Y X.$$

As base changes of disjoint summand inclusions are again disjoint summand inclusions, it will thus suffice to show that the base change of Δ_f along the map $\alpha_1\times\mathrm{id}$ is a disjoint summand inclusion. To this end, consider the following commutative diagram:

$$\begin{array}{ccccc}
A & \xrightarrow{\alpha_1} & X & & \\
{\scriptstyle(\mathrm{id},\alpha_1)}\downarrow & \lrcorner & \downarrow{\scriptstyle\Delta_f} & & \\
A\times_Y X & \xrightarrow{\alpha_1\times\mathrm{id}} & X\times_Y X & \xrightarrow{\mathrm{pr}_2} & X \\
{\scriptstyle\mathrm{pr}_1}\downarrow & \lrcorner & {\scriptstyle\mathrm{pr}_1}\downarrow & \lrcorner & \downarrow{\scriptstyle f} \\
A & \xrightarrow{\alpha_1} & X & \xrightarrow{f} & Y.
\end{array}$$

It follows readily from the pasting law of pullback squares that each square is a pullback square. Observe that the projection map $\mathrm{pr}_1\colon A\times_Y X\to A$ is the base change of f along $f\alpha_1$, hence it lies in $\mathbb{F}_T^P$ by assumption. It follows that the map (id,α_1) is a section of a morphism in $\mathbb{F}_T^P$, hence is a disjoint summand inclusion by the same argument as in the proof of Lemma 4.3.2. This finishes the proof. ☐

For the remainder of this subsection, we will fix an atomic orbital subcategory $P\subseteq T$. We are now ready to define the norm map $\mathrm{Nm}_p\colon p_!\to p_*$ for p as in Proposition 4.3.7.

Construction 4.3.8 (Norm map, cf. [Lur17, Construction 6.1.6.8], [NS18, Construction I.1.7], [HL13, Construction 4.1.8])**.** Let $\mathcal{C}$ be a pointed T-∞-category, let $B \in \mathrm{PSh}(T)$ and let $(p\colon A \to B) \in \underline{\mathbb{F}}_T^P(B)$. Consider the following pullback diagram

$$\begin{array}{ccc} A \times_B A & \xrightarrow{\mathrm{pr}_2} & A \\ {\scriptstyle \mathrm{pr}_1}\downarrow & \lrcorner & \downarrow{\scriptstyle p} \\ A & \xrightarrow{p} & B \end{array} \tag{9}$$

in $\mathrm{PSh}(T)$, and let $\Delta\colon A \to A \times_B A$ denote the diagonal of p. By Proposition 4.3.7, Δ is a disjoint summand inclusion, so that Lemma 4.1.4 provides adjunctions $\Delta_! \dashv \Delta^* \dashv \Delta_*$ and an equivalence $\mathrm{Nm}_\Delta\colon \Delta_! \simeq \Delta_*$.

(1) Define a natural transformation $\alpha\colon \mathrm{pr}_1^* \Rightarrow \mathrm{pr}_2^*$ as the following composite:

$$\mathrm{pr}_2^* \overset{u_\Delta^*}{\Longrightarrow} \Delta_*\Delta^*\mathrm{pr}_2{}^* \simeq \Delta_* \overset{\mathrm{Nm}_\Delta^{-1}}{\simeq} \Delta_! \simeq \Delta_!\Delta^*\,\mathrm{pr}_1^* \overset{c_\Delta^!}{\Longrightarrow} \mathrm{pr}_1^*\,.$$

(2) Assume that $\mathcal{C}$ admits finite P-coproducts, so that the pullback square (9) gives a left base change equivalence $p^*p_! \simeq \mathrm{pr}_{1!}\,\mathrm{pr}_2^*$. We define the *adjoint norm transformation* $\widetilde{\mathrm{Nm}}_p\colon p^*p_! \Rightarrow \mathrm{id}$ *of* p *in* $\mathcal{C}$ as the composite

$$\widetilde{\mathrm{Nm}}_p\colon p^*p_! \overset{l.b.c.}{\simeq} \mathrm{pr}_{1!}\,\mathrm{pr}_2^* \xRightarrow{\mathrm{pr}_{1!}\alpha} \mathrm{pr}_{1!}\,\mathrm{pr}_1^* \overset{c_{\mathrm{pr}_1}^!}{\Longrightarrow} \mathrm{id}\,.$$

(3) Assume that $\mathcal{C}$ admits finite P-products, so that the pullback square (9) gives a right base change equivalence $p^*p_* \simeq \mathrm{pr}_{2*}\,\mathrm{pr}_1^*$. We define the *dual adjoint norm transformation* $\overline{\mathrm{Nm}}_p\colon \mathrm{id} \Rightarrow p^*p_*$ *of* p *in* $\mathcal{C}$ as the composite

$$\overline{\mathrm{Nm}}_p\colon \mathrm{id} \overset{u_{\mathrm{pr}_2}^*}{\Longrightarrow} \mathrm{pr}_{2*}\,\mathrm{pr}_2^* \xRightarrow{\mathrm{pr}_{2*}\alpha} \mathrm{pr}_{2*}\,\mathrm{pr}_1^* \overset{r.b.c.}{\simeq} p^*p_*.$$

(4) Assume that $\mathcal{C}$ admits both finite P-products and finite P-coproducts. We define the *norm transformation of* p *in* $\mathcal{C}$

$$\mathrm{Nm}_p\colon p_! \implies p_*$$

as the map adjoint to the adjoint norm transformation $\widetilde{\mathrm{Nm}}_p\colon p^*p_! \Rightarrow \mathrm{id}$.

We will sometimes write $\widetilde{\mathrm{Nm}}_p^{\mathcal{C}}$, $\overline{\mathrm{Nm}}_p^{\mathcal{C}}$ or $\mathrm{Nm}_p^{\mathcal{C}}$ to emphasize the dependence on $\mathcal{C}$.

Remark 4.3.9. Unwinding the definitions, the map $\widetilde{\mathrm{Nm}}_p\colon p^*p_! \Rightarrow \mathrm{id}$ may be given more directly as the composite

$$p^*p_! \overset{l.b.c.}{\simeq} \mathrm{pr}_{1!}\,\mathrm{pr}_2^* \overset{u_\Delta^*}{\Longrightarrow} \mathrm{pr}_{1!}\Delta_*\Delta^*\,\mathrm{pr}_2^* \overset{\mathrm{Nm}_\Delta^{-1}}{\simeq} \mathrm{pr}_{1!}\Delta_!\Delta^*\,\mathrm{pr}_2^* \simeq \mathrm{id}_{\mathcal{C}(A)}\,.$$

Similarly, the map $\overline{\mathrm{Nm}}_p\colon \mathrm{id} \Rightarrow p^*p_*$ unwinds to the following composite:

$$\mathrm{id}_{\mathcal{C}(A)} \simeq \mathrm{pr}_{2*}\Delta_*\Delta^*\,\mathrm{pr}_1^* \overset{\mathrm{Nm}_\Delta^{-1}}{\simeq} \mathrm{pr}_{2*}\Delta_!\Delta^*\,\mathrm{pr}_1^* \overset{c_\Delta^!}{\Longrightarrow} \mathrm{pr}_{2*}\,\mathrm{pr}_1^* \overset{r.b.c.}{\simeq} p^*p_*.$$

The description of the adjoint norm map $\widetilde{\mathrm{Nm}}$ given above is precisely the definition of the map $\nu_p^{(0)}\colon p^*p_! \Rightarrow \mathrm{id}$ of [HL13, Construction 4.1.8], applied to the Beck-Chevalley fibration $\int \mathcal{C} \to \mathrm{PSh}(T)$ classified by the functor $\mathcal{C}\colon \mathrm{PSh}(T)^{\mathrm{op}} \to \mathrm{Cat}_\infty$. In particular, the norm map $\mathrm{Nm}_p\colon p_! \to p_*$ defined above agrees with the norm map Nm_p of [HL13, Construction 4.1.12].

Remark 4.3.10. Let $(f\colon A \to B) \in \underline{\mathbb{F}}_T^P(B)$ be a morphism in $\mathrm{PSh}(T)$ which happens to be a disjoint summand inclusion. Then the norm map $\mathrm{Nm}_f\colon f_! \Rightarrow f_*$ of Construction 4.3.8 agrees with the map $\mathrm{Nm}_f\colon f_! \Rightarrow f_*$ constructed in Lemma 4.1.4.

The map $\alpha\colon \mathrm{pr}_2^* \Rightarrow \mathrm{pr}_1^*$ defined in Construction 4.3.8(1) may be thought of as some kind of 'diagonal matrix': as the next lemma shows, it restricts to the identity when restricted along the diagonal $\Delta\colon A \hookrightarrow A \times_B A$, and restricts to the zero map on the complement of the diagonal.

Lemma 4.3.11. *Let $\mathcal{C}$ be a pointed T-∞-category and let $(p\colon A \to B) \in \underline{\mathbb{F}}_T^P(B)$. Let $j\colon C \hookrightarrow A \times_B A$ denote the disjoint complement of the diagonal inclusion $\Delta\colon A \hookrightarrow A \times_B A$. Then the following hold:*

(1) The composite $\mathrm{id}_{\mathcal{C}(A)} \simeq \Delta^* \mathrm{pr}_2^* \xrightarrow{\Delta^*\alpha} \Delta^* \mathrm{pr}_1^* \simeq \mathrm{id}_{\mathcal{C}(A)}$ is homotopic to the identity transformation.
(2) The map $j^*\alpha\colon j^* \mathrm{pr}_2^* \Rightarrow j^* \mathrm{pr}_1^*$ is the zero transformation, in the sense that it factors through the zero functor $0\colon \mathcal{C}(A) \to \mathcal{C}(C)$.

Proof. The proof of (1) follows from the following commutative diagram:

$$\begin{array}{ccccccccc}
\Delta^* \mathrm{pr}_2^* & = & \Delta^* \mathrm{pr}_2^* & \xrightarrow{\simeq} & \mathrm{id} & \xrightarrow{\simeq} & \Delta^* \mathrm{pr}_1^* & = & \Delta^* \mathrm{pr}_1^* \\
{\scriptstyle u_\Delta^*}\downarrow & \nearrow{\scriptstyle c_\Delta^*} & & \nearrow{\scriptstyle c_\Delta^*} & & \searrow{\scriptstyle u_\Delta^!} & & \searrow{\scriptstyle u_\Delta^!} & \uparrow{\scriptstyle c_\Delta^!} \\
\Delta^*\Delta_*\Delta^* \mathrm{pr}_2^* & \xrightarrow[\simeq]{} & \Delta^*\Delta_* & & \xrightarrow[\mathrm{Nm}_\Delta^{-1}]{} & & \Delta^*\Delta_! & \xrightarrow[\simeq]{} & \Delta^*\Delta_!\Delta^* \mathrm{pr}_2^*.
\end{array}$$

The triangles on the two sides commute by the triangle identity, the rhombi commute by naturality and the triangle in the middle commutes by the defining property of the norm map Nm_Δ of Lemma 4.1.4.

For (2), note that by definition of α the map $j^*\alpha$ factors through the functor $j^*\Delta_*$. Since coproducts are disjoint in $\mathrm{PSh}(T)$, the fiber product $C \times_{A \times_B A} A$ is the empty presheaf. It then follows from base change that the functor $j^*\Delta_*$ factors through the ∞-category $\mathcal{C}(\emptyset) \simeq *$, which forces it to be the zero functor. $\square$

Remark 4.3.12. In the setting of Mackey 2-functors, Balmer and Dell'Ambrogio [BD20, Theorem 3.3.4] have produced a similar transformation $\Theta_i\colon i_! \Rightarrow i_*$ for i a faithful map of groupoids, i.e. a morphism in $\mathbb{F}_{\mathrm{Glo}}^{\mathrm{Orb}}$. It follows from Lemma 4.3.11 and [BD20, Proposition 3.2.1] that the transformation $\mathrm{Nm}_i\colon i_! \Rightarrow i_*$ of Construction 4.3.8 specializes to the transformation Θ_i of Balmer and Dell'Ambrogio in the case $T = \mathrm{Glo}$ and $P = \mathrm{Orb}$. In particular, if $\mathcal{C}$ is a pointed global ∞-category admitting finite Orb-(co)products, it follows from [BD20, Theorem 3.4.2] that the norm maps Nm_i are equivalences for every faithful map of groupoids $i\colon H \to G$ if and only if there exist abstract equivalences $i_! \simeq i_*$ for every such i.

4.4. **Properties of norm maps.** We will next establish a variety of results about the calculus of norm maps.

To start with, we address the obvious asymmetry in the construction of the norm map: we could just as well have considered the map $p_! \Rightarrow p_*$ adjoint to the *dual* adjoint norm map $\overline{\mathrm{Nm}}_p\colon \mathrm{id} \Rightarrow p^*p_*$. The following lemma shows that these two maps agree.

Lemma 4.4.1. *Assume that $\mathcal{C}$ is a pointed T-∞-category which admits both finite P-products and finite P-coproducts. For every $(p\colon A \to B) \in \underline{\mathbb{F}}_T^P(B)$, the maps $\widetilde{\mathrm{Nm}}_p\colon p^*p_! \Rightarrow \mathrm{id}$ and $\overline{\mathrm{Nm}}_p\colon \mathrm{id} \Rightarrow p^*p_*$ adjoin to the same map $\mathrm{Nm}_p\colon p_! \Rightarrow p_*$.*

Proof. We have to show that dual adjoint norm map $\overline{\mathrm{Nm}}_p$ is the total mate of the adjoint norm map $\widetilde{\mathrm{Nm}}_p$. A mundane exercise in 2-category theory shows that the total mate of the Beck-Chevalley equivalence $p^*p_! \simeq \mathrm{pr}_{1!}\,\mathrm{pr}_2^*$ is the Beck-Chevalley equivalence $\mathrm{pr}_{2*}\,\mathrm{pr}_1^* \simeq p^*p_*$. Furthermore, it follows directly from the triangle identity that the total mate of the composite

$$\mathrm{pr}_{1!}\,\mathrm{pr}_2^* \xRightarrow{\mathrm{pr}_{1!}\alpha} \mathrm{pr}_{1!}\,\mathrm{pr}_1^* \xRightarrow{c^!_{\mathrm{pr}_1}} \mathrm{id}$$

is given by the composite

$$\mathrm{id} \xRightarrow{u^*_{\mathrm{pr}_2}} \mathrm{pr}_{2*}\,\mathrm{pr}_2^* \xRightarrow{\mathrm{pr}_{2*}\alpha} \mathrm{pr}_{2*}\,\mathrm{pr}_1^*\,.$$

Since the total mate of a composite of transformations is given by composing in opposite order the individual total mates of these transformations, this finishes the proof. □

The norm map Nm_p can be written in terms of the double Beck-Chevalley map $p_!\mathrm{pr}_{2*} \Rightarrow p_*\mathrm{pr}_{1!}$ associated to the pullback square (9):

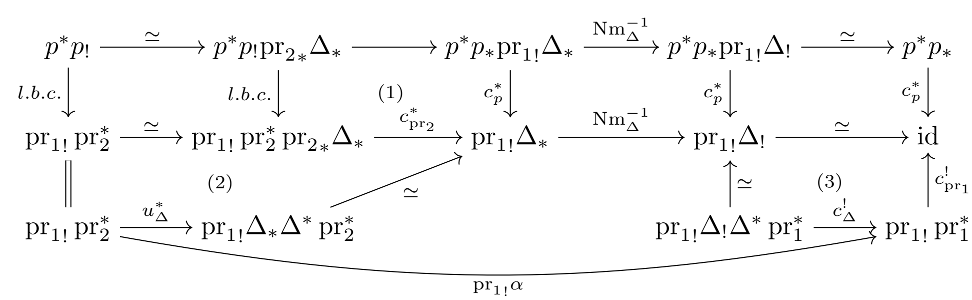
Lemma 4.4.2. *Assume that $\mathcal{C}$ is a pointed T-∞-category which admits both finite P-products and finite P-coproducts, and let $(p\colon A \to B) \in \underline{\mathbb{F}}_T^P(B)$. Then the norm map Nm_p is homotopic to the composite*

$$p_! \simeq p_!\mathrm{pr}_{2*}\Delta_* \to p_*\mathrm{pr}_{1!}\Delta_* \xrightarrow{\mathrm{Nm}_\Delta^{-1}} p_*\mathrm{pr}_{1!}\Delta_! \simeq p_*.$$

Proof. By adjunction, it suffices to show that the adjoint norm map $\widetilde{\mathrm{Nm}}_p\colon p^*p_! \to \mathrm{id}$ is given by the composite

$$p^*p_! \simeq p^*p_!\mathrm{pr}_{2*}\Delta_* \to p^*p_*\mathrm{pr}_{1!}\Delta_* \xrightarrow{\mathrm{Nm}_\Delta^{-1}} p^*p_*\mathrm{pr}_{1!}\Delta_! \simeq p^*p_* \xrightarrow{c_p^*} \mathrm{id}\,.$$

This follows from the following commutative diagram:



The unlabeled squares commute by naturality. Commutativity of (1) is by the triangle identity, while commutativity of (2) and (3) follows from the equivalence $\mathrm{pr}_1 \circ \Delta \simeq \mathrm{id} \simeq \mathrm{pr}_2 \circ \Delta$ and the fact that the (co)unit of a composite of adjunctions is the composite of the individual (co)units. □

As was shown by Hopkins and Lurie [HL13], the norm maps behave well under composition and base change of morphisms in $\underline{\mathbb{F}}_T^P$.

Proposition 4.4.3 ([HL13, Proposition 4.2.1]). *Assume that $\mathcal{C}$ is a pointed T-∞-category which admits finite P-coproducts. Consider a pullback square*

$$\begin{array}{ccc} A' & \xrightarrow{g_A} & A \\ {\scriptstyle p'}\downarrow & \lrcorner & \downarrow{\scriptstyle p} \\ B' & \xrightarrow{g_B} & B \end{array}$$

in $\mathrm{PSh}(T)$ *such that $p \in \underline{\mathbb{F}}_T^P(B)$ and (hence) $p' \in \underline{\mathbb{F}}_T^P(B')$. Then there is a commutative diagram*

$$\begin{array}{ccccc} p'^* p'_! g_A^* & \xrightarrow[\sim]{l.b.c.} & p'^* g_B^* p_! & \xrightarrow{\sim} & g_A^* p^* p_! \\ {\scriptstyle \widetilde{\mathrm{Nm}}_{p'}}\downarrow & & & & \downarrow{\scriptstyle \widetilde{\mathrm{Nm}}_p} \\ g_A^* & & \xlongequal{\qquad\qquad} & & g_A^*. \end{array}$$
□

Corollary 4.4.4 ([HL13, Remark 4.2.3]). *In the situation of Proposition 4.4.3, assume that $\mathcal{C}$ furthermore admits finite P-products. Then the composite*

$$p'_! g_A^* \overset{l.b.c.}{\simeq} g_B^* p_! \xrightarrow{g_B^* \mathrm{Nm}_p} g_B^* p_* \overset{r.b.c.}{\simeq} p'_* g_A^*$$

is homotopic to the map $\mathrm{Nm}_{p'} g_A^*$. □

Proposition 4.4.5 ([HL13, Proposition 4.2.2]). *Assume that $\mathcal{C}$ is a pointed T-∞-category which admits finite P-coproducts. Let $(p\colon A \to B) \in \underline{\mathbb{F}}_T^P(B)$ and $(q\colon B \to C) \in \underline{\mathbb{F}}_T^P(C)$, so that also $(qp\colon A \to C) \in \underline{\mathbb{F}}_T^P(C)$. Then the adjoint norm map $\widetilde{\mathrm{Nm}}_{qp}$ is homotopic to the composite*

$$(qp)^*(qp)_! \simeq p^* q^* q_! p_! \xrightarrow{\widetilde{\mathrm{Nm}}_q} p^* p_! \xrightarrow{\widetilde{\mathrm{Nm}}_p} \mathrm{id}\,.$$
□

Corollary 4.4.6 ([HL13, Remark 4.2.4]). *In the situation of Proposition 4.4.5, assume that $\mathcal{C}$ furthermore admits finite P-products. Then the composite transformation*

$$(qp)_! \simeq q_! p_! \xrightarrow{\mathrm{Nm}_q} q_* p_! \xrightarrow{\mathrm{Nm}_p} q_* p_* \simeq (qp)_*$$

is homotopic to the norm map Nm_{qp}. □

The norm maps are also suitably functorial in the T-∞-category $\mathcal{C}$: as we will now show, any pointed T-functor $G\colon \mathcal{C} \to \mathcal{D}$ transforms norm maps in $\mathcal{C}$ into norm maps in $\mathcal{D}$.

Lemma 4.4.7. *Let $G\colon \mathcal{C} \to \mathcal{D}$ be a pointed T-functor of pointed T-categories and let $(p\colon A \to B) \in \underline{\mathbb{F}}_T^P(B)$. Then the diagram*

$$\begin{array}{ccc} \mathrm{pr}_2^* G & \xrightarrow{\alpha G} & \mathrm{pr}_1^* G \\ \simeq\downarrow & & \downarrow\simeq \\ G\,\mathrm{pr}_2^* & \xrightarrow[G\alpha]{} & G\,\mathrm{pr}_1^* \end{array}$$

of transformations between functors $\mathcal{C}(A) \to \mathcal{D}(A \times_B A)$ commutes.

Proof. Spelling out the definition of α, this is a direct consequence of the following three commutative diagrams:

$$
\begin{array}{ccc}
G & \xrightarrow{u^*_\Delta G} & \Delta_*\Delta^*G \\
{\scriptstyle Gu^*_\Delta}\downarrow & & \downarrow{\scriptstyle \simeq} \\
G\Delta_*\Delta^* & \xrightarrow[\mathrm{BC}_*]{} & \Delta_*G\Delta^*,
\end{array}
\qquad
\begin{array}{ccc}
\Delta_!G & \xrightarrow{\mathrm{Nm}_\Delta G} & \Delta_*G \\
{\scriptstyle \mathrm{BC}_!}\downarrow & & \uparrow{\scriptstyle \mathrm{BC}_*} \\
G\Delta_! & \xrightarrow[G\,\mathrm{Nm}_\Delta]{} & G\Delta_*,
\end{array}
\qquad
\begin{array}{ccc}
\Delta_!\Delta^*G & \xrightarrow{c^!_\Delta G} & G \\
{\scriptstyle \simeq}\uparrow & & \uparrow{\scriptstyle Gc^!_\Delta} \\
\Delta_!G\Delta^* & \xrightarrow[\mathrm{BC}_!]{} & G\Delta_!\Delta^*.
\end{array}
$$

The left and right squares commute by definition of the Beck-Chevalley maps, using the triangle identities. The fact that the middle square commutes follows directly from pointedness of G and the construction of Nm_Δ in Lemma 4.1.4. ☐

Lemma 4.4.8. *Let $G\colon \mathcal{C} \to \mathcal{D}$ be a pointed T-functor between two pointed T-∞-categories which admit finite P-coproducts. Then for every $(p\colon A \to B) \in \underline{\mathbb{F}}^P_T(B)$, the diagram*

$$
\begin{array}{ccccc}
p^*p_!G_A & \xrightarrow{\mathrm{BC}_!} & p^*G_Bp_! & \xrightarrow{\simeq} & G_Ap^*p_! \\
{\scriptstyle \widetilde{\mathrm{Nm}}^{\mathcal{D}}_p G_A}\downarrow & & & & \downarrow{\scriptstyle G_A\widetilde{\mathrm{Nm}}^{\mathcal{C}}_p} \\
G_A & & = & & G_A
\end{array}
$$

commutes.

Proof. Consider the diagram

$$
\begin{array}{ccccc}
p^*p_!G_A & \xrightarrow{\mathrm{BC}_!} & p^*G_Bp_! & \xrightarrow{\simeq} & G_Ap^*p_! \\
\downarrow{\scriptstyle l.b.c.} & & & & {\scriptstyle l.b.c.}\downarrow \\
\mathrm{pr}_{1!}\,\mathrm{pr}_2^*\,G_A & \xrightarrow{\simeq} & \mathrm{pr}_{1!}G_{A\times_BA}\,\mathrm{pr}_2^* & \xrightarrow{\mathrm{BC}_!} & G_A\mathrm{pr}_{1!}\,\mathrm{pr}_2^* \\
\downarrow{\scriptstyle \mathrm{pr}_{1!}\alpha G_A} & & \downarrow{\scriptstyle \mathrm{pr}_{1!}G_{A\times_BA}\alpha} & & {\scriptstyle G_A\mathrm{pr}_{1!}\alpha}\downarrow \\
\mathrm{pr}_{1!}\,\mathrm{pr}_1^*\,G_A & \xrightarrow{\simeq} & \mathrm{pr}_{1!}G_{A\times_BA}\,\mathrm{pr}_1^* & \xrightarrow{\mathrm{BC}_!} & G_A\mathrm{pr}_{1!}\,\mathrm{pr}_1^* \\
\downarrow{\scriptstyle c^!_{\mathrm{pr}_1}G_A} & & & & {\scriptstyle G_Ac^!_{\mathrm{pr}_1}}\downarrow \\
G_A & & = & & G_A.
\end{array}
$$

We are interested in the outer square. The right middle square commute by naturality. The left middle square commutes by Lemma 4.4.7. The bottom rectangle commutes by definition of the Beck-Chevalley map, using the triangle identity. Finally, the upper rectangle commutes as the two composites are the Beck-Chevalley transformations associated to the following two equivalent composite squares:

$$
\begin{array}{ccccc}
\mathcal{C}(B) & \xrightarrow{G_B} & \mathcal{D}(B) & \xrightarrow{p^*} & \mathcal{D}(A) \\
{\scriptstyle p^*}\downarrow & & \downarrow{\scriptstyle p^*} & & \downarrow{\scriptstyle \mathrm{pr}_1^*} \\
\mathcal{C}(A) & \xrightarrow{G_A} & \mathcal{D}(A) & \xrightarrow{\mathrm{pr}_2^*} & \mathcal{D}(A\times_BA)
\end{array}
\quad \text{and} \quad
\begin{array}{ccccc}
\mathcal{C}(B) & \xrightarrow{p^*} & \mathcal{C}(A) & \xrightarrow{G_A} & \mathcal{D}(A) \\
{\scriptstyle p^*}\downarrow & & \downarrow{\scriptstyle \mathrm{pr}_1^*} & & \downarrow{\scriptstyle \mathrm{pr}_1^*} \\
\mathcal{C}(A) & \xrightarrow{\mathrm{pr}_2^*} & \mathcal{C}(A\times_BA) & \xrightarrow{G_{A\times_BA}} & \mathcal{D}(A\times_BA).
\end{array}
$$

This finishes the proof. ☐

We end the subsection with the the following technical lemma, needed for the proof of Proposition 4.5.8 below. We recommend the reader skip this lemma on first reading.

Lemma 4.4.9. *Let $\mathcal{C}$ be a pointed T-∞-category which admits finite P-products. Let $(p\colon A \to B) \in \underline{\mathbb{F}}^P_T(B)$, and assume that p admits a section $s\colon B \to A$ which is a disjoint summand inclusion. Then the composite*

$$s^* \xrightarrow{\simeq} p_*s_*s^* \xrightarrow{p_*\operatorname{Nm}_s^{-1} s^*} p_*s_!s^* \xrightarrow{p_*c^!_s} p_*$$

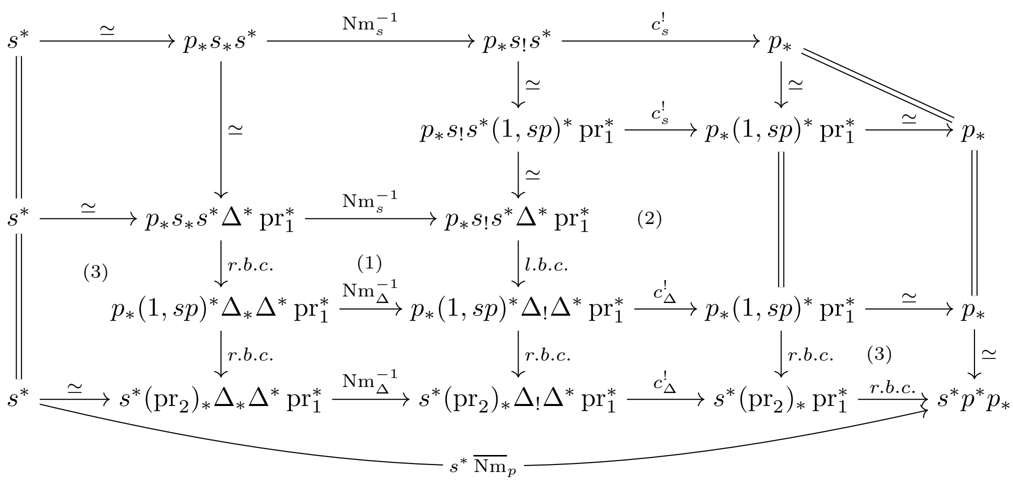
is homotopic to the composite

$$s^* \xrightarrow{s^*\overline{\operatorname{Nm}}_p} s^*p^*p_* \simeq p_*.$$

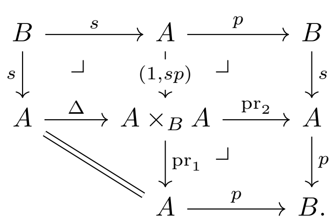
Proof. Recall from Remark 4.3.9 that the map $\overline{\operatorname{Nm}}_p\colon \mathrm{id} \to p^*p_*$ is given by the following composite:

$$\mathrm{id} \simeq \mathrm{pr}_{2*}\Delta_*\Delta^*\,\mathrm{pr}_1^* \xrightarrow{\operatorname{Nm}_\Delta^{-1}} \mathrm{pr}_{2*}\Delta_!\Delta^*\,\mathrm{pr}_1^* \xrightarrow{c^!_\Delta} \mathrm{pr}_{2*}\,\mathrm{pr}_1^* \overset{r.b.c.}{\simeq} p^*p_*.$$

We thus see that the composite $s^* \xrightarrow{s^*\overline{\operatorname{Nm}}_p} s^*p^*p_* \simeq p_*$ is given by the composite along the left, bottom and right in the following large diagram:



The composite along the top of this diagram is the other map appearing in the statement of the lemma, so it will suffice to prove that the diagram commutes. All unlabeled equivalences in this diagram come from identifications on the level of maps in $\mathrm{PSh}(T)$, e.g. we have $p_*s_* \simeq (ps)_* \simeq \mathrm{id}_* \simeq \mathrm{id}$, etcetera. The maps labeled *l.b.c.* and *r.b.c.* are the left/right base change equivalences associated with one of the following three pullback squares in $\mathbb{F}^P_T$:



Except for the squares labelled (1), (2) and (3), all squares in the above diagram commute by naturality. The commutativity of (1) is an instance of Corollary 4.4.4 applied to the previous pullback square exhibiting s as a base change of Δ along $(1, sp)\colon A \to A \times_B A$. The commutativity of (2) follows directly from the definition of the left base change equivalence $s_!s^* \xrightarrow{\sim} (1, sp)^*\Delta_!$, using the triangle identity. Finally, the two squares labeled (3) use that the composite of two right base change equivalences is the right base change equivalence for the composite, which in both cases is just equivalent to the identity. □

4.5. ***P*-semiadditive *T*-∞-categories.** In this section, we will introduce and discuss the notion of a P-semiadditive T-∞-category for a fixed atomic orbital subcategory $P \subseteq T$.

Definition 4.5.1 (cf. [Nar16, Definition 5.3])**.** Let $\mathcal{C}$ be a pointed T-∞-category which admits both finite P-products and finite P-coproducts. We say that $\mathcal{C}$ is P-*semiadditive* if for every morphism $p\colon A \to B$ in $\mathbb{F}_T^P$ the norm map $\mathrm{Nm}_p\colon p_! \Rightarrow p_*$ is an equivalence.

We let $\mathrm{Cat}_T^{P\text{-}\times} \subseteq \mathrm{Cat}_T$ denote the (non-full) subcategory spanned by the T-∞-categories which admit finite P-products and the T-functors which preserve finite P-products. We let $\mathrm{Cat}_T^{P\text{-}\oplus} \subseteq \mathrm{Cat}_T^{P\text{-}\times}$ denote the full subcategory spanned by the P-semiadditive T-∞-categories.

Example 4.5.2. The previous definition applied to the pair $\mathrm{Orb} \subset \mathrm{Glo}$ gives a notion of Orb-semiadditivity for global ∞-categories. We will refer to this as *equivariant semiadditivity.*

It follows directly that also the norm maps for more general morphisms in $\underline{\mathbb{F}}_T^P$ are equivalences:

Corollary 4.5.3. *Let $\mathcal{C}$ be a P-semiadditive T-∞-category, let $B \in \mathrm{PSh}(T)$ and let $(p\colon A \to B) \in \underline{\mathbb{F}}_T^P(B)$. Then the norm map $\mathrm{Nm}_p\colon p_! \Rightarrow p_*$ is an equivalence.*

Proof. We may write the presheaf B as a colimit $\mathrm{colim}_i\, B_i$ of representables $B_i \in T$, which gives rise to an equivalence of ∞-categories $\mathcal{C}(B) \simeq \lim_i \mathcal{C}(B_i)$. It will thus suffice to show that for every representable $B' \in T$ and any morphism $g\colon B' \to B$ of presheaves, the transformation $g^*\,\mathrm{Nm}_p\colon g^*p_! \Rightarrow g^*p_*$ is an equivalence. By Corollary 4.4.4, it will suffice to show that the transformation $\mathrm{Nm}_{p'}\colon p'_! \Rightarrow p'_*$ is an equivalence, where $p'\colon A \times_B B' \to B'$ is the base change of p along g. Since this base change is a morphism in $\mathbb{F}_T^P$, this holds by assumption on $\mathcal{C}$. □

We will next discuss various alternative characterizations of P-semiadditivity. We start by observing that this condition is self-dual.

Lemma 4.5.4. *Let $\mathcal{C}$ be a pointed T-∞-category. Then the following conditions are equivalent:*

(1) The T-∞-category $\mathcal{C}$ is P-semiadditive;
(2) The opposite T-∞-category $\mathcal{C}^{\mathrm{op}}$ is P-semiadditive;
(3) The T-∞-category $\mathcal{C}$ admits finite P-coproducts and for every morphism $p\colon A \to B$ in $\mathbb{F}_T^P$ the adjoint norm map $\widetilde{\mathrm{Nm}}_p\colon p^*p_! \Rightarrow \mathrm{id}$ is the counit of an adjunction $p^* \dashv p_!$;
(4) The T-∞-category $\mathcal{C}$ admits finite P-products and for every morphism $p\colon A \to B$ in $\mathbb{F}_T^P$ the dual adjoint norm map $\overline{\mathrm{Nm}}_p\colon \mathrm{id} \Rightarrow p^*p_*$ is the unit of an adjunction $p_* \dashv p^*$.

Proof. Observe that the dual adjoint norm map $\overline{\mathrm{Nm}}_p\colon \mathrm{id} \Rightarrow p^*p_*$ may be obtained by applying the construction of the adjoint norm map $\widetilde{\mathrm{Nm}}\colon p^*p_! \Rightarrow \mathrm{id}$ to the T-∞-category $\mathcal{C}^{\mathrm{op}}$. The equivalence between (1) and (2) is then immediate from Lemma 4.4.1. The equivalence between (1) and (3) is clear since the norm map $\mathrm{Nm}_p\colon p_! \Rightarrow p_*$ is adjoint to $\widetilde{\mathrm{Nm}}\colon p^*p_! \Rightarrow \mathrm{id}$. The equivalence between (2) and (4) is obtained dually by replacing $\mathcal{C}$ with $\mathcal{C}^{\mathrm{op}}$. ☐

Every choice of an atomic orbital subcategory $P \subseteq T$ gives a different notion of parametrized semiadditivity for a T-∞-category $\mathcal{C}$. The weakest form of parametrized semiadditivity is fiberwise semiadditivity:

Definition 4.5.5. A T-∞-category $\mathcal{C}$ is called *fiberwise semiadditive* if for every $B \in T$ the ∞-category $\mathcal{C}(B)$ is semiadditive and for every morphism $f\colon A \to B$ in T the restriction functor $f^*\colon \mathcal{C}(B) \to \mathcal{C}(A)$ preserves finite biproducts.

Lemma 4.5.6. *Let $\mathcal{C}$ be a pointed T-∞-category which admits fiberwise finite products and coproducts. Then the following three conditions are equivalent:*

(1) The T-∞-category $\mathcal{C}$ is fiberwise semiadditive;
(2) The norm map $\mathrm{Nm}_\nabla\colon \nabla_! \to \nabla_*$ associated to the fold map $\nabla\colon \bigsqcup_{i=1}^n B \to B$ is an equivalence for every $n \geq 0$ and every $B \in T$;
(3) The T-∞-category $\mathcal{C}$ is P-semiadditive for $P = \iota T$, the core of T.

Proof. When $P = \iota T$ is the core of T, any map in $\mathbb{F}_T^P$ is equivalent to a fold map $\nabla\colon \bigsqcup_{i=1}^n B \to B$ for some $B \in T$, and thus the equivalence between (2) and (3) is clear. It remains to show that (1) and (2) are equivalent. The ∞-category $\mathcal{C}(\bigsqcup_{i=1}^n B)$ is equivalent to the n-fold product $\prod_{i=1}^n \mathcal{C}(B)$ of $\mathcal{C}(B)$. Given an object $X = (X_i) \in \prod_{i=1}^n \mathcal{C}(B)$, there are equivalences $\nabla_!(X) \simeq \bigoplus_{i=1}^n X_i$ and $\nabla_*(X) \simeq \prod_{i=1}^n X_i$. By Lemma 4.3.11, the map $\alpha(X)$ is a morphism in $\prod_{i=1}^n \prod_{j=1}^n \mathcal{C}(B)$ which we may visually display as

$$\begin{pmatrix} 1 & 0 & \dots & 0 \\ 0 & 1 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & 1 \end{pmatrix} \colon \begin{pmatrix} X_1 & X_2 & \dots & X_n \\ X_1 & X_2 & \dots & X_n \\ \vdots & \vdots & \ddots & \vdots \\ X_1 & X_2 & \dots & X_n \end{pmatrix} \to \begin{pmatrix} X_1 & X_1 & \dots & X_1 \\ X_2 & X_2 & \dots & X_2 \\ \vdots & \vdots & \ddots & \vdots \\ X_n & X_n & \dots & X_n \end{pmatrix},$$

where 1 denotes an identity map while 0 denotes the zero map. In particular, the induced norm map $\mathrm{Nm}_p\colon \bigoplus_{i=1}^n X_i \to \prod_{j=1}^n X_j$ is induced by the family of maps $\{X_i \to X_j\}_{i,j}$ given by the identity when $i = j$ and the zero-map when $i \neq j$. This is precisely the norm map defining ordinary semiadditivity for ∞-categories, finishing the proof. ☐

As the next result shows, the condition of P-semiadditivity for general P is a combination of fiberwise semiadditivity and norm equivalences $\mathrm{Nm}_p\colon p_! \simeq p_*$ for morphisms p in P.

Corollary 4.5.7. *Let $\mathcal{C}$ be a T-∞-category. Then $\mathcal{C}$ is P-semiadditive if and only if it is fiberwise semiadditive and for every morphism $p\colon A \to B$ in P the norm map $\mathrm{Nm}_p\colon p_! \Rightarrow p_*$ is an equivalence.*

Proof. As in the proof of Proposition 4.2.14, every morphism in $\mathbb{F}_T^P$ with representable domain $B \in T$ can be written as a composite $\bigsqcup_{i=1}^n A_i \xrightarrow{\bigsqcup_{i=1}^n p_i} \bigsqcup_{i=1}^n A_i \xrightarrow{\nabla}$

B for morphisms $p_i\colon A_i \to B$ in P, where ∇ denotes the fold map. The norm map of $\bigsqcup_{i=1}^n p_i\colon \bigsqcup_{i=1}^n A_i \to \bigsqcup_{i=1}^n B$ is equivalent to the product of the norm maps for each individual $p_i\colon A_i \to B$. By Corollary 4.4.6, the norm map of a composite morphism can be written as a composite of norm maps, and it follows that $\mathcal{C}$ is P-semiadditive if and only if the norm maps of all the fold maps $\nabla\colon \bigsqcup_{i=1}^n B \to B$ and of all morphisms $p\colon A \to B$ in P are equivalences. But by Lemma 4.5.6 the norm maps for the fold maps are equivalences if and only if $\mathcal{C}$ is fiberwise semiadditive. □

We finish this subsection with a recognition criterion for P-semiadditivity along the lines of [Lur17, Proposition 2.4.3.19].

Proposition 4.5.8. *Let $\mathcal{C}$ be a pointed T-∞-category admitting finite P-products. Assume that for every morphism $p\colon A \to B$ in $\mathbb{F}_T^P$, there is a natural transformation $\mu_p\colon p_*p^* \Rightarrow \mathrm{id}_{\mathcal{C}(B)}$ of functors $\mathcal{C}(B) \to \mathcal{C}(B)$ satisfying the following two conditions:*

(a) for every $X \in \mathcal{C}(B)$, the composite

$$p^*X \xrightarrow{\overline{\mathrm{Nm}}_p\, p^*X} p^*p_*p^*X \xrightarrow{p^*\mu_p X} p^*X$$

is homotopic to the identity;

(b) for every $Y \in \mathcal{C}(A)$, the following diagram commutes

$$\begin{tikzcd} p_*p^*p_*Y \arrow[r, "\simeq", "r.b.c."'] \arrow[dr, "\mu_p p_* Y"'] & p_*(\mathrm{pr}_2)_*\,\mathrm{pr}_1^*\,Y \arrow[r, "\simeq"] & p_*(\mathrm{pr}_1)_*\,\mathrm{pr}_1^*\,Y \arrow[dl, "p_*\mu_{\mathrm{pr}_1} Y"] \\ & p_*Y. & \end{tikzcd}$$

Then the T-∞-category $\mathcal{C}$ is P-semiadditive.

Proof. To show that $\mathcal{C}$ is P-semiadditive, we may by Lemma 4.5.4 equivalently show that for every map $p\colon A \to B$ in $\mathbb{F}_T^P$ and every object $Y \in \mathcal{C}(A)$, the dual adjoint norm map $\overline{\mathrm{Nm}}_p\, Y\colon Y \Rightarrow p^*p_*Y$ exhibits p_*Y as a left adjoint object to Y under the functor $p^*\colon \mathcal{C}(B) \to \mathcal{C}(A)$, i.e. that for every $X \in \mathcal{C}(B)$ the composite

$$\mathrm{Hom}_{\mathcal{C}(B)}(p_*Y, X) \xrightarrow{p^*} \mathrm{Hom}_{\mathcal{C}(A)}(p^*p_*Y, p^*X) \xrightarrow{-\circ\overline{\mathrm{Nm}}_p\, Y} \mathrm{Hom}_{\mathcal{C}(A)}(Y, p^*X)$$

is an equivalence. We claim that an inverse is given by

$$\mathrm{Hom}_{\mathcal{C}(A)}(Y, p^*X) \xrightarrow{p_*} \mathrm{Hom}_{\mathcal{C}(B)}(p_*Y, p_*p^*X) \xrightarrow{\mu_p X\circ -} \mathrm{Hom}_{\mathcal{C}(B)}(p_*Y, X).$$

By naturality of μ_p and Nm_p, it suffices to prove that the following two composites are homotopic to the identity for every *fixed* X:[3]

$$p^*X \xrightarrow{\overline{\mathrm{Nm}}_p\, p^*X} p^*p_*p^*X \xrightarrow{p^*\mu_p X} p^*X,$$

$$p_*Y \xrightarrow{p_*\,\overline{\mathrm{Nm}}_p\, Y} p_*p^*p_*Y \xrightarrow{\mu_p p_* Y} p_*Y.$$

The first composite is homotopic to the identity by condition (a), so we focus on the second composite. Plugging in the description of $\overline{\mathrm{Nm}}_p$ given in Remark 4.3.9,

[3]While this suffices to show that Nm_p is a unit of an adjunction, it does not show that μ_p is the corresponding counit, as we do not provide homotopies that are functorial in X and Y.

this composite expands to

$$\begin{array}{l} p_*Y \xrightarrow{\sim} p_*\mathrm{pr}_{2*}\Delta_*\Delta^*\,\mathrm{pr}_1^*\,Y \xrightarrow[\sim]{\mathrm{Nm}_\Delta^{-1}} p_*\mathrm{pr}_{2*}\Delta_!\Delta^*\,\mathrm{pr}_1^*\,Y \\ \qquad\qquad\qquad\qquad\qquad\qquad \downarrow c^!_\Delta \\ \qquad\qquad\qquad p_*\mathrm{pr}_{2*}\,\mathrm{pr}_1^*\,Y \xrightarrow[\sim]{r.b.c.} p_*p^*p_*Y \xrightarrow{\mu_p p_* Y} p_*Y, \end{array}$$

which, using condition (b) and the equivalence $p \circ \mathrm{pr}_1 \simeq p \circ \mathrm{pr}_2$, is homotopic to the composite

$$p_*Y \simeq p_*\mathrm{pr}_{1*}\Delta_*\Delta^*\,\mathrm{pr}_1^*\,Y \xrightarrow{\mathrm{Nm}_\Delta^{-1}} p_*\mathrm{pr}_{1*}\Delta_!\Delta^*\,\mathrm{pr}_1^*\,Y \xrightarrow{c^!_\Delta} p_*\mathrm{pr}_{1*}\,\mathrm{pr}_1^*\,Y \xrightarrow{p_*\mu_{\mathrm{pr}_1}Y} p_*Y.$$

Applying Lemma 4.4.9 to the map $\mathrm{pr}_1 \colon A \times_B A \to A$ with section $\Delta\colon A \to A \times_B A$, we see that this map is homotopic to the following composite:

$$p_*Y \simeq p_*\Delta^*\,\mathrm{pr}_1^*\,Y \xrightarrow{p_*\Delta^*\,\overline{\mathrm{Nm}}_{\mathrm{pr}_1}\,\mathrm{pr}_1^*\,Y} p_*\Delta^*\,\mathrm{pr}_1^*\,\mathrm{pr}_{1*}\,\mathrm{pr}_1^*\,Y \xrightarrow{p_*\Delta^*\,\mathrm{pr}_1^*\,\mu_{\mathrm{pr}_1}Y} p_*\Delta^*\,\mathrm{pr}_1^*\,Y \simeq p_*Y.$$

This map is homotopic to the identity by assumption (a) applied to the map $\mathrm{pr}_1 \colon A \times_B A \to A$, finishing the proof. □

4.6. ***P*-semiadditive *T*-functors.** We continue to fix an atomic orbital subcategory $P \subseteq T$. In this subsection we will define what it means for a T-functor $F\colon \mathcal{C} \to \mathcal{D}$ to be P-*semiadditive*: roughly speaking, it means that F turns finite P-coproducts in $\mathcal{C}$ into finite P-products in $\mathcal{D}$. The main result of this subsection is Proposition 4.6.13, which states that the T-subcategory $\underline{\mathrm{Fun}}_T^{P\text{-}\oplus}(\mathcal{C},\mathcal{D})$ of $\underline{\mathrm{Fun}}_T(\mathcal{C},\mathcal{D})$ spanned by the P-semiadditive T-functors is P-semiadditive.

We start by constructing a 'relative' variant of the norm map.

Construction 4.6.1. Let $F\colon \mathcal{C} \to \mathcal{D}$ be a T-functor such that $\mathcal{C}$ is pointed and admits finite P-coproducts and $\mathcal{D}$ admits finite P-products, let $B \in \mathrm{PSh}(T)$ and let $(p\colon A \to B) \in \underline{\mathbb{F}}_T^P(B)$. We define the *norm transformation of* p *relative to* F

$$\mathrm{Nm}_p^F \colon F_B \circ p_! \implies p_* \circ F_A$$

as the transformation adjoint to the composite $p^*F_Bp_! \simeq F_Ap^*p_! \xRightarrow{F_A\,\widetilde{\mathrm{Nm}}_p^{\mathcal{C}}} F_A$, where the first equivalence uses that the parametrized functor $F\colon \mathcal{C} \to \mathcal{D}$ commutes with the restriction functors.

Note that when $\mathcal{D}$ is equal to $\mathcal{C}$ and F is the identity on $\mathcal{C}$, the transformation Nm_p^F reduces to the norm transformation $\mathrm{Nm}_p^{\mathcal{C}}\colon p_! \Rightarrow p_*$ of Construction 4.3.8.

Definition 4.6.2. Let $F\colon \mathcal{C} \to \mathcal{D}$ be a T-functor such that $\mathcal{C}$ is pointed and admits finite P-coproducts and $\mathcal{D}$ admits finite P-products. We will say that F is P-*semiadditive* if it satisfies the following condition:

(∗) For each morphism $p\colon A \to B$ in $\mathbb{F}_T^P$, the transformation $\mathrm{Nm}_p^F\colon F_B \circ p_! \Rightarrow p_* \circ F_A$ defined in Construction 4.6.1 is a natural equivalence.

By Example 4.2.8(1) we also obtain a notion of P-semiadditive $T_{/B}$-functors for all $B \in T$. Note that $\mathcal{C}$ is P-semiadditive if and only if the identity $\mathrm{id}\colon \mathcal{C} \to \mathcal{C}$ is P-semiadditive. Also note that condition (∗) specializes for $A = \emptyset$ to the condition that the functor $F_B\colon \mathcal{C}(B) \to \mathcal{D}(B)$ sends the zero object of $\mathcal{C}(B)$ to the final object of $\mathcal{D}(B)$.

Just like in Corollary 4.5.3, one immediately deduces that the relative norm maps are equivalnces for arbitrary morphisms in $\underline{\mathbb{F}}_T^P$:

Corollary 4.6.3. *Let $F\colon \mathcal{C} \to \mathcal{D}$ as in Construction 4.6.1 and assume that F is P-semiadditive. Then for every $B \in \mathrm{PSh}(T)$ and every $(p\colon A \to B) \in \underline{\mathbb{F}}_T^P(B)$, the transformation $\mathrm{Nm}_p^F\colon F_B \circ p_! \Rightarrow p_* \circ F_A$ is an equivalence.* □

While not necessary for our work, we show for completeness that our norm map generalizes the analogous construction in [Nar16].

Proposition 4.6.4. *Let T be an atomic orbital ∞-category, let $B \in T$ and let $p\colon A \to B$ be a morphism in $\mathbb{F}_T$. Let $F\colon \mathcal{C} \to \mathcal{D}$ be a T-functor with $\mathcal{C}$ and $\mathcal{D}$ satisfying the assumptions of Construction 4.6.1. Then the norm transformation $\mathrm{Nm}_p^F\colon F_B \circ p_! \Rightarrow p_* \circ F_A$ of Construction 4.6.1 is homotopic to the transformation defined in* [Nar16, Construction 5.2].

Proof. We will first give an alternative description of the norm map in this special case, and then argue why it agrees with the construction of Nardin. By definition of $\mathbb{F}_T$, we may assume $p\colon A \to B$ to be of the form $p = (p_i)\colon \bigsqcup_{i=1}^n A_i \to B$, where each $A_i \in T$ is representable. Let $\iota_i\colon A_i \hookrightarrow \bigsqcup_{i=1}^n A_i = A$ denote the canonical inclusion, so that $p_i = p \circ \iota_i\colon A_i \to B$. The functor $p_*\colon \mathcal{D}(A) \to \mathcal{D}(B)$ may be decomposed as

$$\mathcal{D}(A) = \mathcal{D}(\bigsqcup_{i=1}^n A_i) \xrightarrow[\simeq]{(\iota_i^*)_i} \prod_{i=1}^n \mathcal{D}(A_i) \xrightarrow{\prod_{i=1}^n p_{i*}} \prod_{i=1}^n \mathcal{D}(B) \xrightarrow{\prod} \mathcal{D}(B),$$

where the last map denotes the multiplication in $\mathcal{D}(B)$. For an object $X = (X_i) \in \mathcal{C}(A) \simeq \prod_{i=1}^n \mathcal{C}(A_i)$ the norm map $\mathrm{Nm}_p^F(X)\colon F_B(p_!(X)) \to p_*F_A(X) \simeq \prod_{i=1}^n p_{i*}(F_{A_i}(X_i))$ is the product of n maps $F_B(p_!(X)) \to p_{i*}(F_{A_i}(X_i))$, where the i-th one is obtained by adjunction from the composite

$$p_i^*F_B(p_!(X)) \simeq F_{A_i}p_i^*p_!X \simeq F_{A_i}\iota_i^*p^*p_!X \xrightarrow{F_{A_i}\iota_i^*\widetilde{\mathrm{Nm}}_p} F_{A_i}\iota_i^*X = F_{A_i}X_i.$$

We will now expand the definition of the map $\iota_i^*\widetilde{\mathrm{Nm}}_p\colon p_i^*p_!X \to X_i$. First notice that the map $\widetilde{\mathrm{Nm}}_p\colon p^*p_!X \to X$ is given by the following composite:

$$p^*p_!X \overset{l.b.c.}{\simeq} \mathrm{pr}_{1!}\,\mathrm{pr}_2^*\,X \xRightarrow{u_\Delta^*} \mathrm{pr}_{1!}\Delta_*\Delta^*\,\mathrm{pr}_2^*\,X \xRightarrow[\simeq]{\mathrm{Nm}_\Delta^{-1}} \mathrm{pr}_{1!}\Delta_!\Delta^*\,\mathrm{pr}_2^*\,X \simeq X.$$

Applying left base change to the pullback diagram

$$\begin{array}{ccccc} A_i \times_B A & \xrightarrow{\iota_i \times_B A} & A_i \times_B A & \xrightarrow{\mathrm{pr}_2} & A \\ {\scriptstyle \mathrm{pr}_1}\downarrow & \lrcorner & {\scriptstyle \mathrm{pr}_1}\downarrow & \lrcorner & \downarrow{\scriptstyle p} \\ A_i & \xrightarrow{\iota_i} & A_i & \xrightarrow{p_i} & B \end{array}$$

gives an equivalence $p_i^*p_!X \simeq \mathrm{pr}_{1!}\,\mathrm{pr}_2^*\,X$. Since T is atomic, the diagonal $\Delta_{p_i}\colon A_i \to A_i \times_B A_i \hookrightarrow \bigsqcup_{i=1}^n A_i \times_B A_i = A_i \times_B A$ is a disjoint summand inclusion. Writing $g\colon C \to A_i \times_B A$ for the complement summand, we observe that $\mathcal{C}(A_i \times_B A) = \mathcal{C}(A_i \sqcup C) \simeq \mathcal{C}(A_i) \times \mathcal{C}(C)$ and that the object $\mathrm{pr}_2^*\,X \in \mathcal{C}(A_i \times_B A)$ corresponds to the pair (X_i, X_C) for some $X_C \in \mathcal{C}(C)$. Plugging in the map $X_C \to *$ to the zero-object $*$ of $\mathcal{C}(C)$ thus gives a map $\mathrm{pr}_{1!}(X_i, X_C) \to \mathrm{pr}_{1!}(X_i, *) \simeq X_i$. Looking at the construction of Nm_Δ in Lemma 4.1.4, one sees that the resulting composite $p_i^* p_! X \to X_i$ is precisely $\iota_i^* \widetilde{\mathrm{Nm}}_p$.

One may now observe that this second description of the norm map is precisely the construction of [Nar16], after making the following translations in notation:

$$B \leftrightarrow V, \qquad A \leftrightarrow U, \qquad p \leftrightarrow I, \qquad \bigsqcup_{i=1}^n A_i \leftrightarrow \bigsqcup_{W \in \mathrm{Orbit(U)}} W,$$
$$p_! \leftrightarrow \bigsqcup_I, \qquad p_i^* \leftrightarrow \delta_{W/V}, \qquad \iota_i \leftrightarrow (W \subseteq U), \qquad \iota_i^* \widetilde{\mathrm{Nm}}_p \leftrightarrow (\chi_{[W\subseteq U]})_*.$$

This finishes the proof. □

Next, we will show that the P-semiadditive T-functors from $\mathcal{C}$ to $\mathcal{D}$ form a parametrized subcategory of $\underline{\mathrm{Fun}}_T(\mathcal{C},\mathcal{D})$. This will rely on the following general criterion in the spirit of Lemma 2.3.17:

Lemma 4.6.5. *Let $f\colon \mathrm{PSh}(S) \to \mathrm{PSh}(T)$ be a cocontinuous functor that preserves pullbacks. Let $P \subset S$ and $Q \subset T$ be atomic orbital subcategories and assume that for every $p\colon A \to B$ in P we have $(f(p)\colon f(A) \to f(B)) \in \underline{\mathbb{F}}_T^Q(f(B))$. Then:*

1. *(1) The functor $f^*\colon \mathrm{Cat}_T \to \mathrm{Cat}_S$ sends (pointed) T-∞-categories with finite Q-coproducts to (pointed) S-∞-categories with finite P-coproducts, and dually for finite Q-products and finite P-products.*
2. *(2) If $F\colon \mathcal{C} \to \mathcal{D}$ is a T-functor such that $\mathcal{C}$ is pointed with finite Q-coproducts and $\mathcal{D}$ has finite Q-products, then the relative norm map $\mathrm{Nm}_p^{f^*F}$ for any $B \in \mathrm{PSh}(T), p \in \underline{\mathbb{F}}_S^P(p)$ agrees with the relative norm map $\mathrm{Nm}_{f(p)}^F$.*
3. *(3) The functor $f^*\colon \mathrm{Cat}_T \to \mathrm{Cat}_S$ sends Q-semiadditive T-categories to P-semiadditive S-categories and Q-semiadditive T-functors to P-semiadditive S-functors.*

Proof. It is clear that f^* preserves pointedness. Moreover, as f preserves coproducts, it more generally maps $\underline{\mathbb{F}}_S^P(B)$ into $\underline{\mathbb{F}}_T^Q(f(B))$, so part (1) is an instance of Lemma 2.3.17 and its dual. Part (2) follows similarly by direct inspection of the construction of the norm maps, and (3) is an immediate consequence of (2). □

Definition 4.6.6. Let $\mathcal{C}$ and $\mathcal{D}$ be T-∞-categories such that $\mathcal{C}$ is pointed and admits finite P-coproducts and $\mathcal{D}$ admits finite P-products. We define $\underline{\mathrm{Fun}}_T^{P\text{-}\oplus}(\mathcal{C},\mathcal{D})$ as the full subcategory $\underline{\mathrm{Fun}}_T(\mathcal{C},\mathcal{D})$ spanned at level $B \in T$ by the P-semiadditive $T_{/B}$-functors $F\colon \pi_B^*\mathcal{C} \to \pi_B^*\mathcal{D}$ for $B \in T$.

This does indeed form a T-subcategory by the previous lemma applied to the maps $T_{/f}\colon T_{/A} \to T_{/B}$ for all $f\colon A \to B$ in T, cf. the proof of Lemma 2.3.23.

We think of a P-semiadditive T-functor as a functor which sends finite P-coproducts to finite P-products. Hence we expect that this condition should be preserved when precomposing (resp. postcomposing) with a T-functor which preserves finite P-coproducts (resp. finite P-products). The following result shows that this is indeed the case.

Proposition 4.6.7. *Let $F\colon \mathcal{C} \to \mathcal{D}$ be a P-semiadditive T-functor, where $\mathcal{C}$ and $\mathcal{D}$ are as in Definition 4.6.2, and let $(p\colon A \to B) \in \underline{\mathbb{F}}_T^P(B)$.*

(1) Let $\mathcal{C}'$ be another pointed T-category admitting finite P-coproducts and let $G\colon \mathcal{C}' \to \mathcal{C}$ be a pointed T-functor which preserves finite P-coproducts. Then the norm map $\mathrm{Nm}_p^{FG}\colon F_B G_B p_! \Rightarrow p_* F_B G_B$ of FG with respect to p is given by the composite

$$\begin{tikzcd} \mathcal{C}'(A) \arrow[r, "G_A"] \arrow[d, "p_!"'] & \mathcal{C}(A) \arrow[r, "F_A"] \arrow[d, "p_!"'] & \mathcal{D}(A) \arrow[d, "p_*"] \\ \mathcal{C}'(B) \arrow[r, "G_B"'] \arrow[ur, Rightarrow, "\mathrm{BC}_!^{-1}"] & \mathcal{C}(B) \arrow[r, "F_B"'] \arrow[ur, Rightarrow, "\mathrm{Nm}_p^F"] & \mathcal{D}(B), \end{tikzcd}$$

where $\mathrm{BC}_!\colon p_! G(A) \xrightarrow{\simeq} G(B) p_!$ denotes the Beck-Chevalley equivalence of G. In particular the composite $F \circ G\colon \mathcal{C}' \to \mathcal{D}$ is again P-semiadditive.

(2) Let $\mathcal{D}'$ be another T-∞-category which admits finite P-products and let $H\colon \mathcal{D} \to \mathcal{D}'$ be a T-functor which preserves finite P-products. Then the norm map $\mathrm{Nm}_p^{HF}\colon H_B F_B p_! \Rightarrow p_* H_B F_B$ of HF at p is given by the composite

$$\begin{tikzcd} \mathcal{C}(A) \arrow[r, "F_A"] \arrow[d, "p_!"'] & \mathcal{D}(A) \arrow[r, "H_A"] \arrow[d, "p_*"] & \mathcal{D}'(A) \arrow[d, "p_*"] \\ \mathcal{C}(B) \arrow[r, "F_B"'] \arrow[ur, Rightarrow, "\mathrm{Nm}_p^F"] & \mathcal{D}(B) \arrow[r, "H_B"'] \arrow[ur, Rightarrow, "\mathrm{BC}_*"] & \mathcal{D}'(B), \end{tikzcd}$$

where $\mathrm{BC}_*\colon H(A) p_* \xrightarrow{\simeq} p_* H(A)$ denotes the Beck-Chevalley equivalence of H. In particular the composite $H \circ F\colon \mathcal{C} \to \mathcal{D}$ is again P-semiadditive.

Proof. The description of Nm_p^{FG} follows from the commutative diagram

$$\begin{tikzcd} F_B G_B p_! \arrow[r, "u_p^*"] \arrow[d, "\mathrm{BC}_!^{-1}"'] & p_* p^* F_B G_B p_! \arrow[r, "\simeq"] \arrow[d, "\mathrm{BC}_!^{-1}"] & p_* F_A p^* G_B p_! \arrow[r, "\simeq"] \arrow[d, "\mathrm{BC}_!^{-1}"] & p_* F_A G_A p^* p_! \arrow[d, "p_* F_A G_A \widetilde{\mathrm{Nm}}_p"] \\ F_B p_! G_A \arrow[r, "u_p^*"] \arrow[rrr, bend right, "\mathrm{Nm}_p^F\, G_A"'] & p_* p^* F_B p_! G_A \arrow[r, "\simeq"] & p_* F_A p^* p_! G_A \arrow[r, "p_* F_A \widetilde{\mathrm{Nm}}_p\, G_A"] & p_* F_A G_A. \end{tikzcd}$$

The middle and left square commute by naturality, and the right square by Lemma 4.4.8. The description of Nm_p^{HF} follows from the commutative diagram

$$\begin{tikzcd} H_B F_B p_! \arrow[r, "H_B u_p^*"'] \arrow[rrr, bend left, "H_B \mathrm{Nm}_p^F"] \arrow[d, "u_p^*"'] & H_B p_* p^* F_B p_! \arrow[r, "\simeq"] \arrow[d, "\mathrm{BC}_*"', "\simeq"] & H_B p_* F_A p^* p_! \arrow[r, "H_B p_* F_A \widetilde{\mathrm{Nm}}_p"'] \arrow[d, "\mathrm{BC}_*"', "\simeq"] & H_B p_* F_A \arrow[d, "\simeq"', "\mathrm{BC}_*"] \\ p_* p^* H_B F_B p_! \arrow[r, "\simeq"'] & p_* H_A p^* F_B p_! \arrow[r, "\simeq"'] & p_* H_A F_A p^* p_! \arrow[r, "p_* H_A F_A \widetilde{\mathrm{Nm}}_p"'] & p_* H_A F_A, \end{tikzcd}$$

where the middle and right square commute by naturality while the left-most square commutes by definition of the Beck-Chevalley equivalence BC_* and the triangle identity. ☐

Corollary 4.6.8. *Let $\mathcal{C}$ and $\mathcal{D}$ be T-∞-categories such that $\mathcal{C}$ is pointed and admits finite P-coproducts, and $\mathcal{D}$ admits finite P-products. Then post-composition with the forgetful functor $\mathcal{D}_* \to \mathcal{D}$ induces an equivalence of T-∞-categories*

$$\underline{\mathrm{Fun}}_T^{P\text{-}\oplus}(\mathcal{C}, \mathcal{D}_*) \xrightarrow{\sim} \underline{\mathrm{Fun}}_T^{P\text{-}\oplus}(\mathcal{C}, \mathcal{D}).$$

Proof. By Corollary 4.1.8 it remains to show that a pointed T-functor $\mathcal{C} \to \mathcal{D}_*$ is P-semiadditive if and only if its composition with $\mathcal{D}_* \to \mathcal{D}$ is P-semiadditive. This follows from Proposition 4.6.7 since the T-functor $\mathcal{D}_* \to \mathcal{D}$ is conservative and preserves T-limits by Lemma 4.1.10. □

Corollary 4.6.9. *Let $\mathcal{C}$ be a pointed T-∞-category which admits finite P-coproducts and let $\mathcal{D}$ be a T-∞-category which admits finite P-products. Let $B \in T$ and consider a $T_{/B}$-functor $F\colon \pi_B^* \mathcal{C} \to \mathcal{D}$. Then $\pi_B^* \mathcal{C}$ is pointed with finite P-coproducts, $\pi_{B*} \mathcal{D}$ has finite P-products, and F is P-semiadditive if and only if the corresponding functor $\widetilde{F}\colon \mathcal{C} \to \pi_{B*} \mathcal{D}$ is P-semiadditive.*

Proof. This follows from Lemma 4.6.5 and Proposition 4.6.7 by the same arguments as in the proof of Proposition 2.3.28. □

Corollary 4.6.10. *Let $\mathcal{C}$ be a pointed T-∞-category with finite coproducts, let $\mathcal{D}$ be a T-∞-category with finite products, and let $X \in \mathrm{PSh}(T)$ arbitrary. Then $(F\colon \mathcal{C} \to \underline{\mathrm{Fun}}_T(\underline{X}, \mathcal{D})) \in \underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D})(X)$ defines an object of $\underline{\mathrm{Fun}}_T^{P\text{-}\oplus}(\mathcal{C}, \mathcal{D})(X)$ if and only if it is P-semiadditive.*

Proof. If X is representable, this is an instance of the previous proposition. In the general case, we then simply observe analogously to the proof of Proposition 2.3.28 that the functors $\underline{\mathrm{Fun}}_T(\underline{X}, \mathcal{D}) \to \underline{\mathrm{Fun}}_T(\underline{A}, \mathcal{D})$ for maps $\underline{A} \to \underline{X}$ with $A \in T$ are jointly conservative and preserve finite P-products, so that the claim follows from Proposition 4.6.7. □

Lemma 4.6.11. *Let $\mathcal{C}$ and $\mathcal{D}$ be T-∞-categories such that $\mathcal{C}$ is pointed and admits finite P-coproducts and $\mathcal{D}$ admits finite P-products. Let $\mathbf{U}$ be a class of T-∞-categories, and assume that $\mathcal{D}$ admits $\mathbf{U}$-limits. Then the T-∞-category $\underline{\mathrm{Fun}}_T^{P\text{-}\oplus}(\mathcal{C}, \mathcal{D})$ also admits $\mathbf{U}$-limits and the inclusion $\underline{\mathrm{Fun}}_T^{P\text{-}\oplus}(\mathcal{C}, \mathcal{D}) \hookrightarrow \underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D})$ preserves $\mathbf{U}$-limits.*

Proof. First note that the T-∞-category $\underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D})$ admits $\mathbf{U}$-limits by Proposition 2.3.24. Let $K \in \mathbf{U}(B)$ be a $T_{/B}$-∞-category in $\mathbf{U}$, and let $F\colon \pi_B^* \mathcal{C} \to \underline{\mathrm{Fun}}_T(K, \pi_B^* \mathcal{D})$ be a P-semiadditive $T_{/A}$-functor. We need to show that the $T_{/B}$-functor $\lim_K F\colon \pi_B^* \mathcal{C} \to \pi_B^* \mathcal{D}$ is again P-semiadditive. To simplify the notation, we will assume that B is the final object of T by replacing T by $T_{/B}$, and thus we may identify $\pi_B^* \mathcal{C}$ and $\pi_B^* \mathcal{D}$ with $\mathcal{C}$ and $\mathcal{D}$, respectively. Since parametrized limits in $\underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{D})$ are computed pointwise by Proposition 2.3.24, the functor $\lim_K F\colon \mathcal{C} \to \mathcal{D}$ is given by the composite

$$\mathcal{C} \xrightarrow{F} \underline{\mathrm{Fun}}_T(K, \mathcal{D}) \xrightarrow{\lim_K} \mathcal{D}\,.$$

Note that the T-functor $\lim_K\colon \underline{\mathrm{Fun}}_T(K, \mathcal{D}) \to \mathcal{D}$, being right adjoint to the diagonal $\mathcal{D} \to \underline{\mathrm{Fun}}_T(K, \mathcal{D})$, preserves all parametrized limits and thus in particular all finite P-products. It then follows from Proposition 4.6.7 that $\lim_K F$ is P-semiadditive as desired. □

Corollary 4.6.12. *Let $\mathcal{C}$ and $\mathcal{D}$ be pointed T-∞-categories admitting finite P-coproducts, and let $\mathcal{E}$ be a T-∞-category admitting finite P-products. Then the composite equivalence*

$$\underline{\mathrm{Fun}}_T(\mathcal{C}, \underline{\mathrm{Fun}}_T(\mathcal{D}, \mathcal{E})) \simeq \underline{\mathrm{Fun}}_T(\mathcal{C} \times \mathcal{D}, \mathcal{E}) \simeq \underline{\mathrm{Fun}}_T(\mathcal{D}, \underline{\mathrm{Fun}}_T(\mathcal{C}, \mathcal{E}))$$

restricts to an equivalence

$$\underline{\mathrm{Fun}}_T^{P\text{-}\oplus}(\mathcal{C}, \underline{\mathrm{Fun}}_T^{P\text{-}\oplus}(\mathcal{D}, \mathcal{E})) \simeq \underline{\mathrm{Fun}}_T^{P\text{-}\oplus}(\mathcal{D}, \underline{\mathrm{Fun}}_T^{P\text{-}\oplus}(\mathcal{C}, \mathcal{E})).$$

Proof. It follows immediately from Lemma 4.6.11 and Proposition 2.3.24 that both sides correspond to the full subcategory of $\underline{\mathrm{Fun}}_T(\mathcal{C} \times \mathcal{D}, \mathcal{E})$ spanned by those T-functors which are P-semiadditive in both variables. Here we say a T-functor $F\colon \mathcal{C} \times \mathcal{D} \to \mathcal{E}$ is *P-semiadditive in both variables* if for every $B \in T$ and $X : \underline{B} \to \mathcal{C}$, the T-functor

$$F(X, -)\colon \mathcal{D} \to \underline{\mathrm{Fun}}_T(\underline{B}, \mathcal{E})$$

adjoint to the composite $\underline{B} \times \mathcal{D} \xrightarrow{X \times \mathcal{D}} \mathcal{C} \times \mathcal{D} \xrightarrow{F} \mathcal{E}$ is P-semiadditive and similarly for every $Y : \underline{B} \to \mathcal{D}$ the T-functor

$$F(-, Y)\colon \mathcal{C} \to \underline{\mathrm{Fun}}_T(\underline{B}, \mathcal{E})$$

adjoint to $\mathcal{C} \times \underline{B} \xrightarrow{\mathcal{C} \times Y} \mathcal{C} \times \mathcal{D} \xrightarrow{F} \mathcal{E}$ is P-semiadditive. □

We now come to the main result of this subsection: the P-semiadditivity of the T-∞-category $\underline{\mathrm{Fun}}_T^{P\text{-}\oplus}(\mathcal{C}, \mathcal{D})$.

Proposition 4.6.13 (cf. [Nar16, Proposition 5.8]). *Let $\mathcal{C}$ and $\mathcal{D}$ be T-∞-categories such that $\mathcal{C}$ is pointed and admits finite P-coproducts and $\mathcal{D}$ admits finite P-products. Then the T-∞-category $\underline{\mathrm{Fun}}_T^{P\text{-}\oplus}(\mathcal{C}, \mathcal{D})$ is P-semiadditive.*

Proof. By Corollary 4.6.8, we may assume that $\mathcal{D}$ is pointed. It follows from Corollary 4.1.9 that $\underline{\mathrm{Fun}}_T^{P\text{-}\oplus}(\mathcal{C}, \mathcal{D})$ is pointed and from Lemma 4.6.11 that $\underline{\mathrm{Fun}}_T^{P\text{-}\oplus}(\mathcal{C}, \mathcal{D})$ admits finite P-products. These are computed pointwise, meaning that for $p\colon A \to B$ in $\mathbb{F}_T^P$ the map

$$p_*\colon \underline{\mathrm{Fun}}^{P\text{-}\oplus}(\mathcal{C}, \underline{\mathrm{Fun}}_T(\underline{A}, \mathcal{D})) \to \underline{\mathrm{Fun}}^{P\text{-}\oplus}(\mathcal{C}, \underline{\mathrm{Fun}}_T(\underline{B}, \mathcal{D}))$$

is given by post-composition with $p_*\colon \underline{\mathrm{Fun}}_T(\underline{A}, \mathcal{D}) \to \underline{\mathrm{Fun}}_T(\underline{B}, \mathcal{D})$.

To show that $\underline{\mathrm{Fun}}_T^{P\text{-}\oplus}(\mathcal{C}, \mathcal{D})$ is P-semiadditive, we will apply the recognition principle from Proposition 4.5.8. For every morphism $p\colon A \to B$ in $\mathbb{F}_T^P$ and every P-semiadditive $T_{/B}$-functor $G\colon \pi_B^* \mathcal{C} \to \pi_B^* \mathcal{D}$, we define a natural transformation $\mu_p G\colon p_* p^* G \to G$. For notational simplicity, we will construct this in the case where $B = 1$ is a terminal object of T; the general case is obtained by replacing T by $T_{/B}$. In this case, $\mu_p G$ is defined as the following composite:

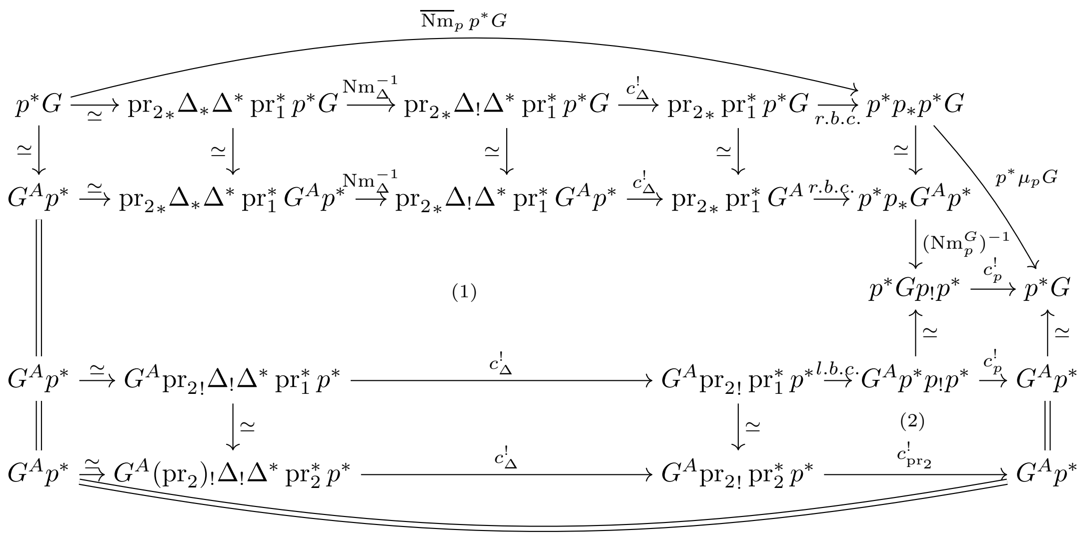
$$p_* p^* G \simeq p_* G^A p^* \xrightarrow{(\mathrm{Nm}_p^G)^{-1}} G p_! p^* \xrightarrow{G c_p^!} G;$$

here we denote by $G^A\colon \underline{\mathrm{Fun}}_T(\underline{A}, \mathcal{C}) \to \underline{\mathrm{Fun}}_T(\underline{A}, \mathcal{D})$ the T-functor induced by G. We need to check that conditions (a) and (b) of Proposition 4.5.8 are satisfied. Condition (b) follows directly from the definitions, using Proposition 4.6.7(2) to compute the norm map of $p_* F$ in terms of the norm map of F and the right base change equivalence $p^* p_* \simeq (\mathrm{pr}_2)_* \mathrm{pr}_1^*$. For condition (a), we need to show that for every P-semiadditive T-functor $G\colon \mathcal{C} \to \mathcal{D}$, the composite

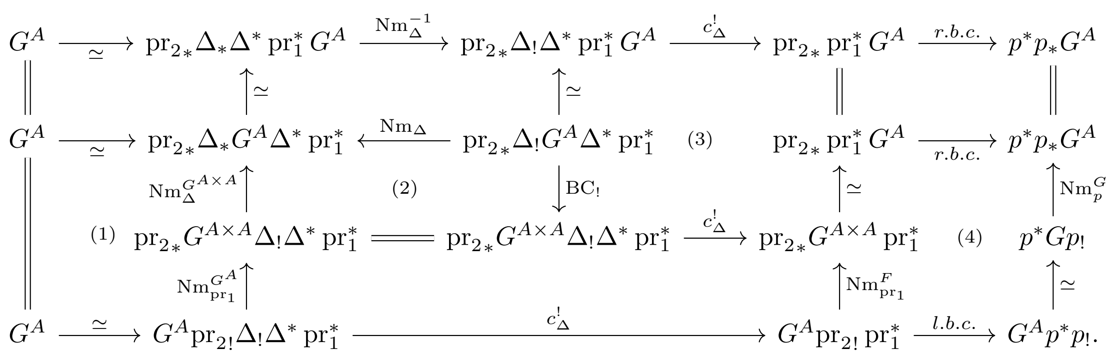
$$p^* G \xrightarrow{\overline{\mathrm{Nm}}_p\, p^* G} p^* p_* p^* G \xrightarrow{p^* \mu_p G} p^* G$$

is homotopic to the identity in $\mathrm{Fun}_{T/A}^{P\text{-}\sqcup}(\pi_A^* \mathcal{C}, \pi_A^* \mathcal{D}) \simeq \mathrm{Fun}_T^{P\text{-}\oplus}(\mathcal{C}, \underline{\mathrm{Fun}}_T(\underline{A}, \mathcal{D}))$. Observe that pointedness of $\mathcal{D}$ guarantees that the transformation $\overline{\mathrm{Nm}}_p\, p^* G\colon p^* G \to p^* p_* p^* G$ is given by whiskering $p^* G$ with the transformation $\overline{\mathrm{Nm}}_p^{\mathcal{D}}\colon \mathrm{id} \to p^* p_*$.

Spelling out the definitions, we are therefore interested in the composite along the top right in the following diagram:



As the composite along the bottom left is the identity, it remains to show that this diagram commutes. Except for (1) and (2), all squares commute either by definition or by naturality, and the commutativity of square (2) follows from the triangle identity. The commutativity of (1) follows from the following commutative diagram:



The unlabeled squares commute by naturality. The fact that (1) commutes follows from Corollary 4.4.6, while the commutativity of (4) follows from Corollary 4.4.4. The commutativity of (2) and (3) easily follows from the definitions. This finishes the proof. □

Proposition 4.6.14. *Let $\mathcal{C}$ be a pointed T-∞-category which admits finite P-coproducts, and suppose $\mathcal{D}$ is P-semiadditive. Then a T-functor $F\colon \mathcal{C} \to \mathcal{D}$ is P-semiadditive if and only if it preserves finite P-coproducts. In particular we get that $\underline{\mathrm{Fun}}_T^{P\text{-}\oplus}(\mathcal{C},\mathcal{D})$ and $\underline{\mathrm{Fun}}_T^{P\text{-}\sqcup}(\mathcal{C},\mathcal{D})$ are the same subcategory of $\underline{\mathrm{Fun}}_T(\mathcal{C},\mathcal{D})$.*

Analogously, suppose $\mathcal{C}$ is a P-semiadditive T-∞-category, and suppose $\mathcal{D}$ admits finite P-products. Then a T-functor $G\colon \mathcal{C} \to \mathcal{D}$ is P-semiadditive if and only if it *preserves finite P-products. In particular $\underline{\mathrm{Fun}}_T^{P\text{-}\oplus}(\mathcal{C},\mathcal{D})$ and $\underline{\mathrm{Fun}}_T^{P\text{-}\times}(\mathcal{C},\mathcal{D})$ are the same subcategory of $\underline{\mathrm{Fun}}_T(\mathcal{C},\mathcal{D})$.*

Proof. We start with the first case. Observe that in both cases F is pointed so that Lemma 4.4.8 applies. Adjoining over p^* to the right gives a commutative triangle

$$\begin{array}{ccc} F_B p_! & & \\ {\scriptstyle \mathrm{BC}_!}\uparrow & \searrow^{\mathrm{Nm}_p^F} & \\ p_! F_A & \xrightarrow[\mathrm{Nm}_p^{\mathcal{D}} F_A]{} & p_* F_A. \end{array}$$

Since $\mathcal{D}$ is a P-semiadditive, the bottom map is an equivalence. It thus follows from the two-out-of-three property that $BC_!\colon p_!F_A \Rightarrow F_B p_!$ is an equivalence if and only if $\mathrm{Nm}_p^F : F_B p_! \Rightarrow p_* F_A$ is, proving the result.

Next we consider the second case. Just as before the result follows from the commutativity of the triangle

$$\begin{array}{ccc} & & p_* F_A \\ & \nearrow^{\mathrm{Nm}_p^F} & \uparrow{\scriptstyle \mathrm{BC}_*} \\ F_B p_! & \xrightarrow[F_B\,\mathrm{Nm}_p^{\mathcal{C}}]{} & F_B p_*, \end{array}$$

which in turn follows from the commutative diagram

$$\begin{array}{ccccc} p_* p^* F_B p_! & \xrightarrow{\simeq} & p_* F_A p^* p_! & \xrightarrow{\widetilde{\mathrm{Nm}}_p^{\mathcal{C}}} & p_* F_A \\ \uparrow{\scriptstyle u_p^*} & & \uparrow{\scriptstyle \mathrm{BC}_*} & & \uparrow{\scriptstyle \mathrm{BC}_*} \\ F_B p_! & \xrightarrow[u_p^*]{} & F_B p_* p^* p_! & \xrightarrow[\widetilde{\mathrm{Nm}}_p^{\mathcal{C}}]{} & F_B p_* \end{array}$$

The left square commutes by the triangle identity and the right by naturality. □

Corollary 4.6.15. *Let $\mathcal{C}$ and $\mathcal{D}$ be P-semiadditive T-∞-categories. Then a T-functor $F\colon \mathcal{C} \to \mathcal{D}$ preserves finite P-coproducts if and only if it preserves finite P-products.* □

There exists a characterization of P-semiadditivity which does not make reference to the norm maps: it suffices for finite P-products to commute with finite P-coproducts.

Corollary 4.6.16. *Let $\mathcal{C}$ be a pointed T-∞-category which admits finite P-products and finite P-coproducts. Then the following conditions are equivalent:*

(1) The T-∞-category $\mathcal{C}$ is P-semiadditive
(2) For every morphism $p\colon A \to B$ in $\mathbb{F}_T^P$, the $T_{/B}$-functor

$$p_*\colon \underline{\mathrm{Fun}}_{T_{/B}}(\underline{A}, \pi_B^*\,\mathcal{C}) \to \pi_B^*\,\mathcal{C}$$

preserves finite P-coproducts.

Proof. Suppose $\mathcal{C}$ is P-semiadditive. Then so are the $T_{/B}$-∞-categories $\pi_B^*\,\mathcal{C}$ and $\mathrm{Fun}_{T_{/B}}(\underline{A}, \pi_B^*\,\mathcal{C})$. Given a morphism $p\colon A \to B$, the $T_{/B}$-functor p_* is a right adjoint of p^* so preserves finite P-products. By Corollary 4.6.15, it follows that p_* also preserves finite P-coproducts, proving that (1) implies (2).

Conversely, applying (2) to the finite P-coproduct $p_!$ gives that the double Beck-Chevalley map $p_!\mathrm{pr}_{2*} \Rightarrow p_*\mathrm{pr}_{1!}$ associated to the pullback square (9) is an equivalence. It thus follows from Lemma 4.4.2 that the norm map Nm_p is an equivalence, showing that (2) implies (1). □

We finish this subsection by observing that passing to the T-∞-category of P-semiadditive T-functors out of a small T-∞-category $\mathcal{C}$ preserves presentability.

Proposition 4.6.17. *Let $\mathcal{C}$ be a small pointed T-∞-category which admits finite P-coproducts. Let $\mathcal{D}$ be a presentable T-∞-category, so that $\mathcal{D}$ in particular admits finite P-products by Remark 2.4.2. Then the T-∞-category $\underline{\mathrm{Fun}}^{P\text{-}\oplus}(\mathcal{C},\mathcal{D})$ is again presentable and the inclusion*

$$\underline{\mathrm{Fun}}^{P\text{-}\oplus}(\mathcal{C},\mathcal{D}) \subset \underline{\mathrm{Fun}}(\mathcal{C},\mathcal{D})$$

admits a left adjoint.

Proof. We will exhibit $\underline{\mathrm{Fun}}_T^{P\text{-}\oplus}(\mathcal{C},\mathcal{D})$ as the T-∞-category of S-local objects for a parametrized family S of morphisms in $\underline{\mathrm{Fun}}_T(\mathcal{C},\mathcal{D})$ (i.e. a set $S(B)$ of morphisms of $\mathrm{Fun}_{T_{/B}}(\pi_B^*\mathcal{C},\pi_B^*\mathcal{D})$ for every $B\in T$ which are closed under restriction). Then Example 2.4.6 implies both statements of the proposition. Since we may prove the statement after pulling back to every slice of T, we may assume without loss of generality that T has a final object. We will describe a set $S'(1)$ of morphisms in $\mathrm{Fun}_T(\mathcal{C},\mathcal{D})$ such that F is P-semiadditive if and only if F is S'-local; the set $S'(B)$ at any other object $B\in T$ is given by the analogous procedure applied to the slice $T_{/B}$. We then define $S(B)$ to be the union of the restriction of $S'(A)$ along every map $A\to B$ in T. Note that a functor F is $S(A)$-local if and only if f_*F is $S'(B)$-local for every $f\colon A\to B$ in T. By Lemma 4.6.11 this is equivalent to F being $S'(A)$-local.

By definition, a T-functor $F\colon \mathcal{C}\to\mathcal{D}$ is T-semiadditive if and only if it preserves T-final objects and the norm map $\mathrm{Nm}_p\colon F_B\circ p_! \Rightarrow p_*\circ F_A$ is an equivalence for every $p\colon A\to B$ in $\mathbb{F}_T^P$. By presentability of $\mathcal{D}(B)$, there exists a set $\{d_i\}$ of generating objects of $\mathcal{D}(B)$ for every $B\in\mathbb{F}_T$, which we may assume to be closed under restriction along maps in $\mathbb{F}_T$. It follows that F is semiadditive if and only if for every morphism $p\colon A\to B$ in $\mathbb{F}_T^P$, every generator $d_i\in\mathcal{D}(B)$ and every $x\in\mathcal{C}(A)$ the following two maps of spaces are equivalences:

(1) $\mathrm{Hom}_{\mathcal{D}(B)}(d_i,F_B(*))\to\mathrm{Hom}_{\mathcal{D}(B)}(d_i,*)\simeq *$;
(2) $\mathrm{Hom}_{\mathcal{D}(B)}(d_i,F_B(p_!(x)))\to\mathrm{Hom}_{\mathcal{D}(B)}(d_i,p_*(F_A(x)))\simeq\mathrm{Hom}_{\mathcal{D}(A)}(p^*(d_i),F_A(x))$.

Note that this is a set worth of conditions. We claim that these maps of spaces are obtained by applying $\mathrm{Hom}_{\mathrm{Fun}_T(\mathcal{C},\mathcal{D})}(-,F)$ to certain maps $S'(1)$ in $\mathrm{Fun}_T(\mathcal{C},\mathcal{D})$. Since the maps are natural in the functor F, it suffices to prove that the source and target of each map are corepresented. Note that the functor $F\mapsto *$ is corepresented by the initial object of $\mathrm{Fun}_T(\mathcal{C},\mathcal{D})$. Therefore it will suffice to show that functors in F of the form $\mathrm{Hom}_{\mathcal{D}(B)}(y,F_B(x))$ are corepresented. First recall the standard fact that the assignment $F\mapsto\mathrm{Hom}_{\mathcal{D}(B)}(d_i,F_B(x))$ is corepresented by the functor $y(x)\otimes d_i\colon \mathcal{C}(B)\to\mathcal{D}(B)$ in $\mathrm{Fun}(\mathcal{C}(B),\mathcal{D}(B))$. Here $y(x)=\mathrm{Hom}_{\mathcal{C}(B)}(x,-)\colon \mathcal{C}(B)\to\mathrm{Spc}$ denotes the Yoneda embedding, while the functor $-\otimes d_i\colon \mathrm{Spc}\to\mathcal{D}(B)$ denotes the standard tensoring over spaces in the cocomplete category $\mathcal{D}(B)$. To prove the claim, it thus remains to show that the evaluation functor

$$\mathrm{ev}_B\colon \mathrm{Fun}_T(\mathcal{C},\mathcal{D}) \to \mathrm{Fun}(\mathcal{C}(B),\mathcal{D}(B))$$

admits a left adjoint. Note that by Proposition 2.3.24 it preserves colimits and limits. Since both source and target are presentable the existence of the required left adjoint follows immediately from the adjoint functor theorem [Lur09, Corollary 5.5.2.9]. □

4.7. **Finite pointed P-sets.** We will now introduce the T-∞-category $\underline{\mathbb{F}}^P_{T,*}$ of *finite pointed P-sets* for an orbital subcategory $P \subseteq T$ and prove that it is the free pointed T-∞-category admitting finite P-coproducts.

Definition 4.7.1. Let $P \subseteq T$ be an orbital subcategory. We define the subcategory $\underline{\mathbb{F}}^P_{T,*} \subseteq \underline{\mathrm{Spc}}_{T,*}$ of *finite pointed P-sets* as the inverse image of the subcategory $\underline{\mathbb{F}}^P_T \subseteq \underline{\mathrm{Spc}}_T$ under the forgetful functor $\underline{\mathrm{Spc}}_{T,*} \to \underline{\mathrm{Spc}}_T$: it contains those pointed T-spaces $(X,f,s) \in \underline{\mathrm{Spc}}_{T,*}(B)$ whose underlying T-space $(f\colon X \to B)$ is in $\underline{\mathbb{F}}^P_T$.

Note that $\underline{\mathbb{F}}^P_{T,*}$ is equivalent to $(\underline{\mathbb{F}}^P_T)_*$, the pointed objects in the T-∞-category of finite P-sets.

Notation 4.7.2. By Example 2.3.3, the forgetful functor $\underline{\mathrm{Spc}}_{T,*} \to \underline{\mathrm{Spc}}_T$ admits a left adjoint $(-)_+\colon \underline{\mathrm{Spc}}_T \to \underline{\mathrm{Spc}}_{T,*}$. It is given at $B \in T$ by the functor

$$(-)_+\colon\ \mathrm{PSh}(T)_{/B} \to (\mathrm{PSh}(T)_{/B})_*\colon (X,f) \mapsto (X_+, f_+, s),$$

where $X_+ := X \sqcup B$, where $f_+ := (f,\mathrm{id})\colon X \sqcup B \to B$ and where $s\colon B \hookrightarrow X \sqcup B$ is the canonical inclusion. We will often abuse notation and write X_+ or $(X,f)_+$ instead of (X_+, f_+, s).

Observe that the T-functor $(-)_+\colon \underline{\mathrm{Spc}}_T \to \underline{\mathrm{Spc}}_{T,*}$ of Notation 4.7.2 restricts to a T-functor $(-)_+\colon \underline{\mathbb{F}}^P_T \to \underline{\mathbb{F}}^P_{T,*}$ which is left adjoint to the forgetful functor $\mathrm{fgt}\colon \underline{\mathbb{F}}^P_{T,*} \to \underline{\mathbb{F}}^P_T$.

Lemma 4.7.3. *Let $P \subseteq T$ be an atomic orbital subcategory. Then the T-functor $(-)_+\colon \underline{\mathbb{F}}^P_T \to \underline{\mathbb{F}}^P_{T,*}$ is essentially surjective: any finite pointed P-set $(Y,p,s) \in \underline{\mathbb{F}}^P_{T,*}(B)$ is equivalent to one of the form X_+ for some $(X,q) \in \underline{\mathbb{F}}^P_T(B)$.*

Proof. By definition, we may write $Y = \bigsqcup_{i=1}^n A_i$ as a finite disjoint union such that each map $p_i\colon A_i \to B$ is in P. The section $s\colon B \to \bigsqcup_{i=1}^n A_i$ must factor as $B \to A_i \hookrightarrow \bigsqcup_{i=1}^n A_i$ for some i. But this implies that the map $B \to A_i$ is a section of $p_i\colon A_i \to B$, so by Lemma 4.3.2 it must be an equivalence, exhibiting B as a disjoint summand of Y. Defining X as the disjoint union of the remaining summands gives the desired equivalence $Y \simeq X_+$ over B. □

Notation 4.7.4. When $P \subseteq T$ is atomic orbital, we will assume all pointed P-set over $B \in T$ are given to us in the form $X_+ = X \sqcup B$ for $(X,q) \in \underline{\mathbb{F}}^P_T(B)$. This convention is justified by Lemma 4.7.3. We emphasize that the maps $X_+ \to Y_+$ of finite pointed P-sets over B are not assumed to respect this decomposition, i.e. they might not be induced by maps in $\mathbb{F}^P_T(B)$.

Lemma 4.7.5. *The T-∞-category $\underline{\mathbb{F}}^P_{T,*}$ from Definition 4.7.1 admits finite P-coproducts and the inclusion $\underline{\mathbb{F}}^P_{T,*} \hookrightarrow \underline{\mathrm{Spc}}_{T,*}$ preserves finite P-coproducts. Furthermore, for any other T-∞-category $\mathcal{D}$ which admits finite P-coproducts, a T-functor*

$F\colon \underline{\mathbb{F}}^P_{T,*} \to \mathcal{D}$ preserves finite P-coproducts if and only if the composite $F \circ (-)_+$ does.

Proof. By Example 2.3.21, it suffices to prove that $\underline{\mathbb{F}}^P_{T,*}$ is closed under finite P-coproducts in $\underline{\mathrm{Spc}}_{T,*}$. By Corollary 4.2.16, the T-category $\underline{\mathbb{F}}^P_T$ admits finite P-coproducts and these are preserved by the (left adjoint) T-functor $(-)_+\colon \underline{\mathbb{F}}^P_T \to \underline{\mathbb{F}}^P_{T,*}$. Conversely it follows from Lemma 4.7.3 that every cocone in $\underline{\mathbb{F}}^P_{T,*}$ indexed by a finite P-set comes from $\underline{\mathbb{F}}^P_T$. The claim follows. □

Let $S^0\colon \underline{1} \to \underline{\mathbb{F}}^P_{T,*}$ denote the T-functor given at $B \in T$ by the object $B_+ \in \underline{\mathbb{F}}^P_{T,*}(B)$. The goal of the remainder of this subsection is to show that this map exhibits the T-∞-category $\underline{\mathbb{F}}^P_{T,*}$ as the free pointed T-∞-category admitting finite P-coproducts.

If $\mathcal{E}$ is an ∞-category admitting a final object $*$, we let $\mathcal{E}_+ \subseteq \mathcal{E}_*$ denote the full subcategory of pointed objects $* \to Z$ for which there exists a pointed equivalence $Z \simeq X \sqcup *$ for some $X \in \mathcal{E}$. If $\mathcal{E}$ admits finite coproducts, then $\mathcal{E}_+$ also admits finite coproducts and the functor $(-)_+\colon \mathcal{E} \to \mathcal{E}_+\colon X \mapsto X_+ := X \sqcup *$ preserves finite coproducts. Furthermore $\mathcal{E}_+$ is pointed. We will show that the functor $(-)_+\colon \mathcal{E} \to \mathcal{E}_+$ is universal among coproduct preserving functors from $\mathcal{E}$ into a pointed ∞-category.

Lemma 4.7.6. *Let $\mathcal{E}$ and $\mathcal{D}$ be ∞-categories admitting finite coproducts. Assume that $\mathcal{E}$ admits a final object and that $\mathcal{D}$ is pointed. Then precomposition with the functor $(-)_+\colon \mathcal{E} \to \mathcal{E}_+$ induces an equivalence*

$$\mathrm{Fun}^{\sqcup,*}(\mathcal{E}_+, \mathcal{D}) \xrightarrow{\sim} \mathrm{Fun}^{\sqcup}(\mathcal{E}, \mathcal{D}).$$

Proof. We claim an inverse is given by sending a finite-coproduct-preserving functor $F\colon \mathcal{E} \to \mathcal{D}$ to the functor $\widetilde{F}\colon \mathcal{E}_+ \to \mathcal{D}$ defined by the formula

$$\widetilde{F}(X_+) := \mathrm{cofib}(F(*) \to F(X_+)).$$

Observe that this colimit exists and is equivalent to $F(X)$ by the following pushout diagram:

$$\begin{array}{ccccc} * & \longrightarrow & F(*) & \longrightarrow & * \\ \downarrow & \ulcorner & \downarrow & & \downarrow \\ F(X) & \longrightarrow & F(X_+) & \longrightarrow & F(X). \end{array}$$

Here the left square is a pushout since $\mathcal{D}$ is pointed and F preserves finite coproducts, and it thus follows from the pasting law of pushout diagrams that the right square is a pushout as well. This proves that the composition $\widetilde{F} \circ (-)_+$ is equivalent to F. It is easily observed that $\widetilde{F}$ is pointed and preserves finite coproducts.

Now assume we are given a pointed functor $\widetilde{F}\colon \mathcal{E}_+ \to \mathcal{D}$ which preserves finite coproducts. It remains to show that for every object $Z \in \mathcal{E}_+$ the canonical map

$$\mathrm{cofib}(\widetilde{F}(*_+) \to \widetilde{F}(Z_+)) \to \widetilde{F}(Z)$$

is an equivalence. This follows from the fact that Z_+ is a coproduct in $\mathcal{E}_+$ of Z and $*_+$ and that $\widetilde{F}$ preserves coproducts by assumption. □

Let $\mathrm{Cat}_\infty^{\sqcup} \subseteq \mathrm{Cat}_\infty$ denote the (non-full) subcategory consisting of ∞-categories which admit finite coproducts and functors which preserve finite coproducts. Let $\mathrm{Cat}_\infty^{\sqcup,\mathrm{pt}} \subseteq \mathrm{Cat}_\infty^{\sqcup,*} \subseteq \mathrm{Cat}_\infty^{\sqcup}$ denote the full subcategories spanned by those ∞-categories with finite coproducts which admit a zero object or admit a final object, respectively.

Corollary 4.7.7. *The inclusion* $\mathrm{Cat}_\infty^{\sqcup,\mathrm{pt}} \hookrightarrow \mathrm{Cat}_\infty^{\sqcup,*}$ *admits a left adjoint*

$$(-)_+ \colon \mathrm{Cat}_\infty^{\sqcup,*} \to \mathrm{Cat}_\infty^{\sqcup,\mathrm{pt}}$$

which on objects sends $\mathcal{E}$ *to* $\mathcal{E}_+$.

Proof. We need to show that for any $\mathcal{E} \in \mathrm{Cat}_\infty^{\sqcup,*}$ and any $\mathcal{D} \in \mathrm{Cat}_\infty^{\sqcup,\mathrm{pt}}$, the precomposition with the map $(-)_+ \colon \mathcal{E} \to \mathcal{E}_+$ induces an equivalence

$$\mathrm{Hom}_{\mathrm{Cat}_\infty^{\sqcup}}(\mathcal{E}_+, \mathcal{D}) \xrightarrow{\sim} \mathrm{Hom}_{\mathrm{Cat}_\infty^{\sqcup}}(\mathcal{E}, \mathcal{D}).$$

This is immediate from Lemma 4.7.6. $\square$

Corollary 4.7.8. *Let* $\mathcal{D}$ *be a pointed* T*-*∞*-category* $\mathcal{D}$ *which admits finite* P*-coproducts. Then composition with* $S^0 \colon \underline{1} \to \underline{\mathbb{F}}_{T,*}^P$ *induces an equivalence of* T*-*∞*-categories*

$$\underline{\mathrm{Fun}}_T^{P\text{-}\sqcup,*}(\underline{\mathbb{F}}_{T,*}^P, \mathcal{D}) \to \underline{\mathrm{Fun}}_T(\underline{1}, \mathcal{D}) \simeq \mathcal{D}\,.$$

Proof. Note that S^0 is the composite $\underline{1} \xrightarrow{*} \underline{\mathbb{F}}_T^P \xrightarrow{(-)_+} \underline{\mathbb{F}}_{T,*}^P$. By Corollary 4.2.17 it thus suffices to show that composition with the T-functor $(-)_+ \colon \underline{\mathbb{F}}_T^P \to \underline{\mathbb{F}}_{T,*}^P$ induces an equivalence $\underline{\mathrm{Fun}}_T^{P\text{-}\sqcup,*}(\underline{\mathbb{F}}_{T,*}^P, \mathcal{D}) \xrightarrow{\sim} \underline{\mathrm{Fun}}_T^{P\text{-}\sqcup}(\underline{\mathbb{F}}_T^P, \mathcal{D})$. It in fact suffices to show that it induces an equivalence between T-∞-categories of *fiberwise coproduct* preserving functors. Namely by the last part of Lemma 4.7.5 this equivalence will restrict to the subcategories of P-coproduct preserving functors on either side. Replacing T by $T_{/B}$ for every $B \in T$, it suffices to prove this on underlying ∞-categories. Note that the subcategory $\mathrm{Cat}_T^{\sqcup} \subseteq \mathrm{Cat}_T$ is closed under cotensoring by Cat_∞ and that there is a canonical equivalence $\mathrm{Hom}_{\mathrm{Cat}_\infty}(\mathcal{E}, \mathrm{Fun}_T^{\sqcup}(\mathcal{C}, \mathcal{D})) \simeq \mathrm{Hom}_{\mathrm{Cat}_T^{\sqcup}}(\mathcal{C}, \mathcal{D}^{\mathcal{E}})$ for $\mathcal{E} \in \mathrm{Cat}_\infty$ and $\mathcal{C}, \mathcal{D} \in \mathrm{Cat}_T^{\sqcup}$. By the Yoneda lemma it will thus suffice to show that the functor $(-)_+ \colon \underline{\mathbb{F}}_T^P \to \underline{\mathbb{F}}_{T,*}^P$ induces an equivalence $\mathrm{Hom}_{\mathrm{Cat}_T^{\sqcup}}(\underline{\mathbb{F}}_{T,*}^P, \mathcal{D}) \xrightarrow{\sim} \mathrm{Hom}_{\mathrm{Cat}_T^{\sqcup}}(\underline{\mathbb{F}}_T^P, \mathcal{D})$. This is immediate from Corollary 4.7.7. $\square$

4.8. *P*-commutative monoids.

In this subsection we will introduce the notion of a *P-commutative monoid* in a T-∞-category $\mathcal{D}$ admitting finite P-products. Furthermore we will show that the T-∞-category $\underline{\mathrm{CMon}}^P(\mathcal{D})$ of P-commutative monoids in $\mathcal{D}$ is the terminal P-semiadditive T-∞-category equipped with a finite P-product preserving T-functor to $\mathcal{D}$.

Definition 4.8.1 (P-commutative monoids, cf. [Nar16, Definition 5.9])**.** Let $\mathcal{D}$ be a T-∞-category which admits finite P-products. A *P-commutative monoid object of* $\mathcal{D}$ is a P-semiadditive T-functor $M \colon \underline{\mathbb{F}}_{T,*}^P \to \mathcal{D}$. We define the T-∞-category $\underline{\mathrm{CMon}}^P(\mathcal{D})$ of *P-commutative monoids* in $\mathcal{D}$ as

$$\underline{\mathrm{CMon}}^P(\mathcal{D}) := \underline{\mathrm{Fun}}_T^{P\text{-}\oplus}(\underline{\mathbb{F}}_{T,*}^P, \mathcal{D}).$$

We define the forgetful functor $\mathbb{U} \colon \underline{\mathrm{CMon}}^P(\mathcal{D}) \to \mathcal{D}$ to be given by precomposition with the T-functor $S^0 \colon \underline{1} \to \underline{\mathbb{F}}_{T,*}^P$.

As a special case, we define the T-∞-category $\underline{\mathrm{CMon}}_T^P$ of *P-commutative monoids* as

$$\underline{\mathrm{CMon}}_T^P := \underline{\mathrm{CMon}}^P(\underline{\mathrm{Spc}}_T).$$

Combining our previous results, we can immediately deduce the universal property of P-commutative monoids. We spell this out in the following series of statements.

Proposition 4.8.2. *For every T-∞-category $\mathcal{D}$ admitting finite P-products, the T-∞-category $\underline{\mathrm{CMon}}^P(\mathcal{D})$ is P-semiadditive. Furthermore, the forgetful functor $\underline{\mathrm{CMon}}^P(\mathcal{D}) \to \mathcal{D}$ preserves finite P-products.*

Proof. The first statement is a special case of Proposition 4.6.13 for $\mathcal{C} = \underline{\mathbb{F}}_{T,*}^P$. The second statement is a special case of Lemma 4.6.11 combined with Proposition 2.3.24. □

Proposition 4.8.3. *Given a T-∞-category $\mathcal{D}$ admitting finite P-products,*

$$\mathbb{U} \colon \underline{\mathrm{CMon}}^P(\mathcal{D}) \to \mathcal{D}$$

is an equivalence if and only if $\mathcal{D}$ is P-semiadditive.

Proof. As $\underline{\mathrm{CMon}}^P(\mathcal{D})$ is P-semiadditive by Proposition 4.8.2, one direction is immediate. Conversely, if $\mathcal{D}$ is P-semiadditive, then Proposition 4.6.14 provides an equivalence

$$\underline{\mathrm{CMon}}^P(\mathcal{D}) = \underline{\mathrm{Fun}}_T^{P\text{-}\oplus}(\underline{\mathbb{F}}_{T,*}^P, \mathcal{D}) \simeq \underline{\mathrm{Fun}}_T^{P\text{-}\sqcup}(\underline{\mathbb{F}}_{T,*}^P, \mathcal{D}).$$

The result thus follows from Corollary 4.7.8. □

Corollary 4.8.4 (cf. [Nar16, Corollary 5.11.1])**.** *Let $\mathcal{C}$ and $\mathcal{D}$ be T-∞-categories such that $\mathcal{C}$ is pointed and admits finite P-coproducts and $\mathcal{D}$ admits finite P-products. Then postcomposition with the forgetful functor $\mathbb{U} \colon \underline{\mathrm{CMon}}^P(\mathcal{D}) \to \mathcal{D}$ induces an equivalence*

$$\mathrm{Fun}_T^{P\text{-}\sqcup}(\mathcal{C}, \underline{\mathrm{CMon}}^P(\mathcal{D})) \to \mathrm{Fun}_T^{P\text{-}\oplus}(\mathcal{C}, \mathcal{D}).$$

Proof. By Proposition 4.6.14, the left-hand side is equal to the T-∞-category of P-semiadditive T-functors $\mathcal{C} \to \underline{\mathrm{CMon}}^P(\mathcal{D})$. By Corollary 4.6.12 this is in turn equivalent to $\underline{\mathrm{CMon}}^P(\underline{\mathrm{Fun}}_T^{P\text{-}\oplus}(\mathcal{C}, \mathcal{D}))$. The claim thus follows from Proposition 4.8.2 and Proposition 4.8.3. □

Corollary 4.8.5. *The inclusion $\mathrm{Cat}_T^{P\text{-}\oplus} \hookrightarrow \mathrm{Cat}_T^{P\text{-}\times}$ of the T-∞-category of P-semiadditive T-∞-categories and P-semiadditive T-functors into the T-∞-category of T-∞-categories admitting finite P-products and the finite P-product preserving T-functors admits a right adjoint given by*

$$\underline{\mathrm{CMon}}^P(-) \colon \mathrm{Cat}_T^{P\text{-}\times} \to \mathrm{Cat}_T^{P\text{-}\oplus}. \qquad \square$$

We are also interested in a presentable version of Corollary 4.8.5.

Lemma 4.8.6. *Let $\mathcal{C}$ be presentable. Then $\mathbb{U} \colon \underline{\mathrm{CMon}}^P(\mathcal{C}) \to \mathcal{C}$ admits a left adjoint $\mathbb{P}$.*

Proof. The functor $\mathrm{ev}_{S^0} \colon \underline{\mathrm{Fun}}_T(\underline{\mathbb{F}}_{T,*}^P, \mathcal{C}) \to \mathcal{C}$ admits a left adjoint by [MW21, Theorem 6.3.5 and Corollary 6.3.7]. The claim follows as also the inclusion $\underline{\mathrm{CMon}}^P(\mathcal{C}) \hookrightarrow \underline{\mathrm{Fun}}_T(\underline{\mathbb{F}}_{T,*}^P, \mathcal{C})$ admits a left adjoint by Proposition 4.6.17. □

Definition 4.8.7. We define $\mathrm{Pr}_T^{\mathrm{R},P\text{-}\oplus}$ to be the full subcategory of $\mathrm{Pr}_T^{\mathrm{R}}$ spanned by those presentable T-∞-categories which are moreover P-semiadditive. Similarly we define $\mathrm{Pr}_T^{\mathrm{L},P\text{-}\oplus}$.

Proposition 4.8.8. *The functor* $\underline{\mathrm{CMon}}^P$ *restricts to a functor*

$$\underline{\mathrm{CMon}}^P\colon \mathrm{Pr}_T^{\mathrm{R}} \to \mathrm{Pr}_T^{\mathrm{R},P\text{-}\oplus}$$

right adjoint to the inclusion.

Proof. Let $\mathcal{C}$ be a presentable T-∞-category. Note that by Proposition 4.6.17, $\underline{\mathrm{CMon}}^P(\mathcal{C})$ is again presentable. Furthermore suppose $G\colon \mathcal{C} \to \mathcal{D}$ is a right adjoint between presentable T-∞-categories, and denote its left adjoint by F. Note that G preserves finite P-products, and so induces a functor $\underline{\mathrm{CMon}}^P(G)\colon \underline{\mathrm{CMon}}^P(\mathcal{C}) \to \underline{\mathrm{CMon}}^P(\mathcal{D})$. Because G preserves local objects, the composite

$$\underline{\mathrm{CMon}}^P(\mathcal{D}) \hookrightarrow \underline{\mathrm{Fun}}_T(\underline{\mathbb{F}}_{T,*}^P, \mathcal{D}) \xrightarrow{F} \underline{\mathrm{Fun}}_T(\underline{\mathbb{F}}_{T,*}^P, \mathcal{C}) \xrightarrow{L^{P\text{-}\oplus}(-)} \underline{\mathrm{CMon}}^P(\mathcal{C})$$

is left adjoint to $\underline{\mathrm{CMon}}^P(R)$, where $L^{P\text{-}\oplus}$ refers to the left adjoint of the inclusion $\underline{\mathrm{CMon}}^P \subset \underline{\mathrm{Fun}}_T(\underline{\mathbb{F}}_{T,*}^P, \mathcal{C})$ constructed in Proposition 4.6.17.

Finally, the unit $\mathbb{U}$ is a right adjoint by Lemma 4.8.6 while the counit is even an equivalence by Proposition 4.8.3. □

Corollary 4.8.9. *There exists an adjunction*

$$\underline{\mathrm{CMon}}^P(-)\colon \mathrm{Pr}_T^{\mathrm{L}} \rightleftarrows \mathrm{Pr}_T^{\mathrm{L},P\text{-}\oplus} :\mathrm{incl}.$$

Furthermore the unit $\mathbb{P}\colon \mathcal{C} \to \underline{\mathrm{CMon}}^P(\mathcal{C})$ *is left adjoint to the forgetful functor* $\mathbb{U}$.

Proof. Consider the adjunction constructed in Proposition 4.8.8 and apply the equivalence $\mathrm{Pr}_T^{\mathrm{L}} \simeq (\mathrm{Pr}_T^{\mathrm{R}})^{\mathrm{op}}$. □

For ease of reference we record the strongest results obtained above in one omnibus theorem:

Theorem 4.8.10. *Let* $\mathcal{C}$ *be a* T-∞-*category with finite* P-*products. The functor* $\mathbb{U}\colon \underline{\mathrm{CMon}}^P(\mathcal{C}) \to \mathcal{C}$ *exhibits* $\underline{\mathrm{CMon}}^P(\mathcal{C})$ *as the* P-*semiadditive envelope of* $\mathcal{C}$, *i.e. for every* P-*semiadditive* T-∞-*category* $\mathcal{D}$ *postcomposition with* $\mathbb{U}$ *induces an equivalence*

$$\underline{\mathrm{Fun}}^{P\text{-}\times}(\mathcal{D}, \mathbb{U})\colon \underline{\mathrm{Fun}}^{P\text{-}\oplus}(\mathcal{D}, \underline{\mathrm{CMon}}^P(\mathcal{C})) \to \underline{\mathrm{Fun}}^{P\text{-}\times}(\mathcal{D}, \mathcal{C}).$$

Suppose now that $\mathcal{D}$ *is moreover presentable. Then the left adjoint* $\mathbb{P}$ *of* $\mathbb{U}$ *exhibits* $\underline{\mathrm{CMon}}^P(\mathcal{C})$ *as the presentable* P-*semiadditive completion of* $\mathcal{C}$, *i.e. for any presentable* P-*semiadditive* T-∞-*category* $\mathcal{D}$ *precomposition with* $\mathbb{P}$ *yields an equivalence*

$$\underline{\mathrm{Fun}}^{\mathrm{L}}(\mathbb{P}, \mathcal{D})\colon \underline{\mathrm{Fun}}^{\mathrm{L}}(\underline{\mathrm{CMon}}^P(\mathcal{C}), \mathcal{D}) \to \underline{\mathrm{Fun}}^{\mathrm{L}}(\mathcal{C}, \mathcal{D}).$$ □

Combining the result above with the universal property of $\underline{\mathrm{Spc}}_T$ already shows that we have for any presentable P-semiadditive T-∞-category $\mathcal{D}$ an equivalence $\underline{\mathrm{Fun}}_T^{\mathrm{L}}(\underline{\mathrm{CMon}}_T^P, \mathcal{D}) \simeq \mathcal{D}$ of T-∞-categories. As our final result in this subsection we will generalize this to the case where $\mathcal{D}$ is merely assumed to be T-cocomplete:

Theorem 4.8.11. *Let $\mathcal{D}$ be a locally small T-cocomplete P-semiadditive T-∞-category. Then evaluation at $\mathbb{P}(*)$ defines an equivalence*

$$\underline{\mathrm{Fun}}^{\mathrm{L}}_T(\underline{\mathrm{CMon}}^P_T, \mathcal{D}) \xrightarrow{\simeq} \mathcal{D}. \tag{10}$$

Proof. Appealing to the universal property of $\underline{\mathrm{Spc}}_T$ and passing to adjoints, we see that (10) agrees up to equivalence with the map

$$\underline{\mathrm{Fun}}^{\mathrm{R}}_T(\mathcal{D}, \mathbb{U})\colon \underline{\mathrm{Fun}}^{\mathrm{R}}_T(\mathcal{D}, \underline{\mathrm{CMon}}^P_T) \to \underline{\mathrm{Fun}}^{\mathrm{R}}_T(\mathcal{D}, \underline{\mathrm{Spc}}_T)$$

between parametrized categories of *right adjoint* functors. In particular it is fully faithful by the first half of Theorem 4.8.10, so it only remains to prove essential surjectivity.

Replacing $\mathcal{D}$ by $\underline{\mathrm{Fun}}_T(\underline{A}, \mathcal{D})$ for $A \in T$, it will be enough to construct for every $X \in \Gamma(\mathcal{D})$ a T-left adjoint $F\colon \underline{\mathrm{CMon}}^P \to \mathcal{D}$ with $F(\mathbb{P}(*)) \simeq X$.

For this, we use the universal property of $\underline{\mathbb{F}}^P_{T,*}$ (Lemma 4.7.8) to obtain a P-coproduct preserving functor $\varphi\colon \underline{\mathbb{F}}^P_{T,*} \to \mathcal{D}^{\mathrm{op}}$ sending S^0 to X, which we may then extend to a left adjoint $\Phi\colon \underline{\mathrm{Fun}}_T(\underline{\mathbb{F}}^P_{T,*}, \underline{\mathrm{Spc}}_T) \to \mathcal{D}$ via Proposition 2.4.9. To complete the proof it suffices now to prove that Φ factors through the Bousfield localization $L^{P\text{-}\oplus}\colon \mathrm{Fun}_T(\underline{\mathbb{F}}^P_{T,*}, \underline{\mathrm{Spc}}_T) \to \underline{\mathrm{CMon}}^P$, or equivalently that its right adjoint takes values in $\underline{\mathrm{CMon}}^P$. However, by Remark 2.4.10 the value of this right adjoint on $Y \in \mathcal{D}(A)$ is given by the composite

$$\pi_A^*\underline{\mathbb{F}}^P_{T,*} \xrightarrow{\pi_A^*\varphi} \pi_A^*\mathcal{D}^{\mathrm{op}} \xrightarrow{\mathrm{maps}(-,Y)} \mathrm{Spc}_{T/A} \simeq \pi_A^*\underline{\mathrm{Spc}}_T$$

and the first functor sends π_A^*P-coproducts to π_A^*P-products by construction of φ and semiadditivity of $\mathcal{D}$ while the second one even preserves all π_A^*T-limits that exist in $\pi_A^*\mathcal{D}^{\mathrm{op}}$ [MW21, Corollary 4.4.9]. □

For use in future work, we record the following result elaborating on the construction of the inverse to (10):

Proposition 4.8.12. *Write $j\colon (\underline{\mathbb{F}}^P_{T,*})^{\mathrm{op}} \to \underline{\mathrm{CMon}}^P_T$ for the unique finite P-product preserving functor sending S^0 to $\mathbb{P}(*)$. Then the restriction $j^*\colon \underline{\mathrm{Fun}}_T(\underline{\mathrm{CMon}}^P_T, \mathcal{D}) \to \underline{\mathrm{Fun}}_T((\underline{\mathbb{F}}^P_{T,*})^{\mathrm{op}}, \mathcal{D})$ admits a left adjoint $j_!$, and j^* and $j_!$ restrict to mutually inverse equivalences $\underline{\mathrm{Fun}}^{\mathrm{L}}_T(\underline{\mathrm{CMon}}^P_T, \mathcal{D}) \simeq \underline{\mathrm{Fun}}^{P\text{-}\times}_T((\underline{\mathbb{F}}^P_{T,*})^{\mathrm{op}}, \mathcal{D})$.*

Proof. Let us write $\bar{\jmath}$ for the composition of the Yoneda embedding $y\colon (\underline{\mathbb{F}}^P_{T,*})^{\mathrm{op}} \to \underline{\mathrm{Fun}}_T(\underline{\mathbb{F}}^P_{T,*}, \underline{\mathrm{Spc}}_T)$ with the localization $L^{P\text{-}\oplus}$. We will first prove the proposition with $\bar{\jmath}$ in lieu of j, and then conclude in the end that in fact $j \simeq \bar{\jmath}$.

[MW21, Theorem 7.1.1] shows that for any T-cocomplete (P-semiadditive) $\mathcal{D}$ the restriction $y^*\colon \underline{\mathrm{Fun}}_T(\underline{\mathrm{Fun}}_T(\underline{\mathbb{F}}^P_{T,*}, \underline{\mathrm{Spc}}_T), \mathcal{D}) \to \underline{\mathrm{Fun}}_T((\underline{\mathbb{F}}^P_{T,*})^{\mathrm{op}}, \mathcal{D})$ has a left adjoint $y_!$ inducing an equivalence $\underline{\mathrm{Fun}}_T((\underline{\mathbb{F}}^P_{T,*})^{\mathrm{op}}, \mathcal{D}) \simeq \underline{\mathrm{Fun}}^{\mathrm{L}}_T(\underline{\mathrm{Fun}}_T(\underline{\mathbb{F}}^P_{T,*}, \underline{\mathrm{Spc}}_T), \mathcal{D})$, while Theorem 6.3.5 and Corollary 6.3.7 of *op. cit.* show that $\bar{\jmath}^*$ admits a left adjoint $\bar{\jmath}_!$.

We claim that $\bar{\jmath}_!$ and $\bar{\jmath}^*$ restrict to functors $\underline{\mathrm{Fun}}^{P\text{-}\times}_T((\underline{\mathbb{F}}^P_{T,*})^{\mathrm{op}}, \mathcal{D}) \rightleftarrows \underline{\mathrm{Fun}}^{\mathrm{L}}_T(\underline{\mathrm{CMon}}^P_T, \mathcal{D})$, which are then automatically adjoint to each other again. As the right adjoint $\bar{\jmath}^*$ in this adjunction is then moreover an equivalence by the previous theorem together with Corollary 4.7.8, they will then be mututally inverse equivalences.

To prove the claim, note that we have seen in the proof of the previous theorem that $y_!\colon \underline{\mathrm{Fun}}^{P\text{-}\times}_T((\underline{\mathbb{F}}^P_{T,*})^{\mathrm{op}}, \underline{\mathrm{Spc}}_T) \to \underline{\mathrm{Fun}}^{\mathrm{L}}_T(\underline{\mathrm{Fun}}_T(\underline{\mathbb{F}}^P_{T,*}, \underline{\mathrm{Spc}}_T), \mathcal{D})$ factors through the fully faithful functor $(L^{P\text{-}\oplus})^*\colon \underline{\mathrm{Fun}}^{\mathrm{L}}_T(\underline{\mathrm{CMon}}^P_T,\mathcal{D}) \to \underline{\mathrm{Fun}}^{\mathrm{L}}_T(\underline{\mathrm{Fun}}_T(\underline{\mathbb{F}}^P_{T,*},\underline{\mathrm{Spc}}_T),\mathcal{D})$. If we write f for the resulting functor $\underline{\mathrm{Fun}}^{P\text{-}\times}_T((\underline{\mathbb{F}}^P_{T,*})^{\mathrm{op}},\underline{\mathrm{Spc}}_T) \to \underline{\mathrm{Fun}}^{\mathrm{L}}_T(\underline{\mathrm{CMon}}^P_T,\mathcal{D})$, then for any $A\in T$, $X\in \underline{\mathrm{Fun}}^{P\text{-}\times}_T((\underline{\mathbb{F}}^P_{T,*})^{\mathrm{op}},\mathcal{D})(A)$, and $Y\in \underline{\mathrm{Fun}}_T(\underline{\mathrm{CMon}}^P_T,\mathcal{D})(A)$

$$\begin{aligned}\mathrm{maps}(f(X),Y) &\simeq \mathrm{maps}((L^{P\text{-}\oplus})^*f(X),(L^{P\text{-}\oplus})^*Y) \simeq \mathrm{maps}(y_!X,(L^{P\text{-}\oplus})^*Y)\\ &\simeq \mathrm{maps}(X,y^*(L^{P\text{-}\oplus})^*Y) = \mathrm{maps}(X,\bar{\jmath}^*Y) \simeq \mathrm{maps}(\bar{\jmath}_!X,Y)\end{aligned}$$

by full faithfulness, the definition of f, and adjunction, respectively. It follows from the ordinary Yoneda Lemma that $f(X)\simeq \bar{\jmath}_!(X)$, and in particular the latter lives in $\underline{\mathrm{Fun}}^{\mathrm{L}}_T(\underline{\mathrm{CMon}}^P_T,\mathcal{D})(A)$, i.e. $\bar{\jmath}_!$ maps $\underline{\mathrm{Fun}}^{P\text{-}\times}_T((\underline{\mathbb{F}}^P_{T,*})^{\mathrm{op}},\mathcal{D})$ into $\underline{\mathrm{Fun}}^{\mathrm{L}}_T(\underline{\mathrm{CMon}}^P_T,\mathcal{D})$.

Conversely, any T-cocontinuous $\underline{\mathrm{CMon}}^P_T\to\mathcal{D}$ has to arise via the construction of the previous theorem, i.e. f is essentially surjective. But $\bar{\jmath}^*f = y^*(L^{P\text{-}\oplus})^*f\simeq y^*y_!\simeq \mathrm{id}$, so $\bar{\jmath}^*$ restricts to

$$\bar{\jmath}^*\colon \underline{\mathrm{Fun}}^{\mathrm{L}}_T(\underline{\mathrm{CMon}}^P_T,\mathcal{D}) \to \underline{\mathrm{Fun}}^{P\text{-}\times}_T((\underline{\mathbb{F}}^P_{T,*})^{\mathrm{op}},\mathcal{D}). \tag{11}$$

It only remains to show that $\bar{\jmath}$ agrees with j as constructed in the statement of the proposition. As $\bar{\jmath}(S^0)\simeq\mathbb{P}(*)$, we only need to show that $\bar{\jmath}$ preserves finite P-products. But this follows at once by taking $\mathcal{D}=\underline{\mathrm{CMon}}^P_T$ and chasing the identity through (11). □

We can now slightly strengthen the second half of Theorem 4.8.10 in the case of $\underline{\mathrm{Spc}}_T$:

Corollary 4.8.13. *Let $\mathcal{S}$ be a T-∞-category equivalent to $\underline{\mathrm{Spc}}_T$ and let $\mathcal{D}$ be any locally small P-semiadditive T-cocomplete T-∞-category. Then precomposition with the T-functor $\mathbb{P}\colon\mathcal{S}\to\underline{\mathrm{CMon}}^P(\mathcal{S})$ induces an equivalence*

$$\underline{\mathrm{Fun}}^{\mathrm{L}}_T(\underline{\mathrm{CMon}}^P(\mathcal{S}),\mathcal{D}) \xrightarrow{\simeq} \underline{\mathrm{Fun}}^{\mathrm{L}}_T(\mathcal{S},\mathcal{D}).$$ □

Remark 4.8.14. We will prove in forthcoming work that Corollary 4.8.13 in fact holds for any presentable T-∞-category $\mathcal{S}$.

4.9. **Commutative monoids in $\underline{\mathcal{E}}_T$.** Let $\mathcal{E}$ be an ∞-category. Recall that a T-functor $F\colon\underline{\mathbb{F}}^P_{T,*}\to\underline{\mathcal{E}}_T$ corresponds to a functor $\widetilde{F}\colon\int\underline{\mathbb{F}}^P_{T,*}\to\mathcal{E}$ of ∞-categories, see Lemma 2.2.13. We will now give a characterization of those functors $\widetilde{F}$ whose associated T-functor F is a P-semiadditive monoid in $\underline{\mathcal{E}}_T$. We start with an explicit description of the adjoint norm map $\widetilde{\mathrm{Nm}}_p\colon p^*p_!\Rightarrow\mathrm{id}$ associated to $\underline{\mathbb{F}}^P_{T,*}$.

Lemma 4.9.1. *Let $P\subseteq T$ be an atomic orbital subcategory. Consider a map $p\colon A\to B$ in $\mathbb{F}^P_T$ and let $f\colon X\to A$ and $g\colon Y\to A$ be a morphisms in $\mathrm{PSh}(T)$. Then the map $1\times_p 1\colon X\times_A Y\to X\times_B Y$ is a disjoint summand inclusion.*

Proof. Using Proposition 4.3.7, this follows directly from the observation that the map $X\times_A Y\to X\times_B Y$ is a base change of the disjoint summand inclusion $\Delta\colon A\to A\times_B A$ along the map $f\times_B g\colon X\times_B Y\to A\times_B A$. □

Construction 4.9.2. Consider a morphism $p\colon A\to B$ in $\mathbb{F}^P_T$. For any finite P-set $(X,q)\in\underline{\mathbb{F}}^P_T(A)$, the unit map $(1,q)\colon X\to X\times_B A = p_*p_!X$ is a disjoint summand inclusion by Lemma 4.9.1, and thus we may choose an identification

$$X\times_B A\simeq X\sqcup J_X$$

for some finite P-set $J_X \in \underline{\mathbb{F}}_T^P(A)$. In particular we obtain a map $p^*p_!(X_+) \to X_+$ in $\underline{\mathbb{F}}_T^P(A)$ defined as the following composite:

$$p^*p_!(X_+) \simeq (X \times_B A)_+ \simeq (X \sqcup J_X)_+ \to X_+,$$

where the last map projects away the disjoint component J_X to the disjoint basepoint.

Lemma 4.9.3. *The map $p^*p_!(X_+) \to X_+$ constructed in Construction 4.9.2 is homotopic to the adjoint norm map $\widetilde{\mathrm{Nm}}_p\colon p^*p_!(X_+) \to X_+$ associated to the T-∞-category $\underline{\mathbb{F}}_{T,*}^P$.*

Proof. Choose a map $J_A \hookrightarrow A \times_B A$ exhibiting J_A as a complement of the disjoint summand inclusion $\Delta\colon A \hookrightarrow A \times_B A$. The resulting equivalence $A \times_B A \simeq A \sqcup J_A$ induces an equivalence $\underline{\mathbb{F}}_{T,*}^P(A \times_B A) \simeq \underline{\mathbb{F}}_{T,*}^P(A \sqcup J_A) \simeq \underline{\mathbb{F}}_{T,*}^P(A) \times \underline{\mathbb{F}}_{T,*}^P(J_A)$. Pulling back the decomposition $A \times_B A \simeq A \sqcup J_A$ along the map $X \times_B A \to A \times_B A$ gives a decomposition $X \times_B A \simeq X \sqcup J_X$, and it follows that the object $\mathrm{pr}_2^*(X_+) \simeq (X \times_B A)_+ \in \underline{\mathbb{F}}_{T,*}^P(A \times_B A)$ corresponds to the pair $(X_+, J_{X+}) \in \underline{\mathbb{F}}_{T,*}^P(A) \times \underline{\mathbb{F}}_{T,*}^P(J_A)$. By Lemma 4.3.11, the transformation $\alpha\colon \mathrm{pr}_2^* \Rightarrow \mathrm{pr}_1^*$ corresponds to a transformation of functors into $\underline{\mathbb{F}}_{T,*}^P(A) \times \underline{\mathbb{F}}_{T,*}^P(J_A)$ which on the first component is the identity and on the second component is the zero-map which projects everything onto the disjoint basepoint. The description from Construction 4.9.2 follows. □

Notation 4.9.4. We will abuse notation and denote objects of the unstraightening $\int \underline{\mathbb{F}}_{T,*}^P$ by pairs (A, X_+), where $A \in T$ and $(X, q\colon X \to A) \in \underline{\mathbb{F}}_T^P(A)$ is a finite P-set. We will specify q explicitly whenever confusion might arise.

Construction 4.9.5 (Parametrized Segal map)**.** Consider a map $p\colon A \to B$ in P, a map $C \to B$ in T and a finite pointed P-set $X_+ \to A$ in $\underline{\mathbb{F}}_{T,*}^P(A)$. Since p is in P, the pullback $A \times_B C$ of p along $C \to B$ may be written as a disjoint union of maps $p_i\colon C_i \to C$ in P:

$$\begin{array}{ccc} \bigsqcup_{i=1}^n C_i & \longrightarrow & A \\ {\scriptstyle (p_i)_{i=1}^n}\downarrow & \lrcorner & \downarrow{\scriptstyle p} \\ C & \longrightarrow & B. \end{array}$$

We will we construct for each $i \in \{1, \dots, n\}$ a *parametrized Segal map*

$$\rho_i\colon (C, (X \times_B C)_+) \to (C_i, (X \times_A C_i)_+)$$

in $\int \underline{\mathbb{F}}_{T,*}^P$. To give such a map, we need to provide a map $C_i \to C$ in T, which we simply take to be the map $p_i\colon C_i \to C$, and a map $p_i^*(X \times_B C)_+ \simeq (X \times_B C_i)_+ \to (X \times_A C_i)_+$ in $\underline{\mathbb{F}}_{T,*}^P(C_i)$. Recall from Lemma 4.9.1 that the map $X \times_A C_i \to X \times_B C_i$ is a disjoint summand inclusion, so that we may choose an equivalence

$$(X \times_B C_i) \simeq (X \times_A C_i) \sqcup J_i,$$

where $J_i \to C_i$ is some finite P-set. The required map $(X \times_B C_i)_+ \simeq (X \times_A C_i)_+ \vee J_{i+} \to (X \times_A C_i)_+$ is now given by projecting away the second summand.

Proposition 4.9.6. *Let $\mathcal{E}$ be an ∞-category and consider a T-functor $F\colon \underline{\mathbb{F}}_{T,*}^P \to \underline{\mathcal{E}}_T$. Denote by $\widetilde{F}\colon \int \underline{\mathbb{F}}_{T,*}^P \to \mathcal{E}$ the functor associated to F under the equivalence of Lemma 2.2.13. Then F is a P-semiadditive monoid in $\underline{\mathcal{E}}_T$ if and only if F is* *fiberwise semiadditive and for every map $p\colon A \to B$ in P, every map $f\colon C \to B$ in T and every finite pointed P-set $X_+ \in \underline{\mathbb{F}}^P_{T,*}(A)$, the map*

$$(\widetilde{F}(\rho_i))_{i=1}^n \colon \widetilde{F}(C, (X \times_B C)_+) \to \prod_{i=1}^n \widetilde{F}(C_i, (X \times_A C_i)_+)$$

induced by the parametrized Segal maps is an equivalence.

Proof. By Corollary 4.5.7, the T-functor F is P-semiadditive if and only if it is fiberwise semiadditive and for all maps $p\colon A \to B$ in P the transformation $\mathrm{Nm}^F_p \colon F_B \circ p_! \Rightarrow p_* \circ F_A$ of functors $\underline{\mathbb{F}}^P_{T,*}(A) \to \underline{\mathcal{E}}_T(B) = \mathrm{Fun}(T^{\mathrm{op}}_{/B}, \mathcal{E})$ is an equivalence. Since we may check this pointwise, it suffices to show that for every finite P-set $X_+ \in \underline{\mathbb{F}}^P_{T,*}(A)$ and every object $f\colon C \to B$ of $T_{/B}$, the induced map

$$F_B(p_!(A, X_+))(C, f) \to (p_*(F_A(A, X_+))(C, f)$$

is an equivalence. By definition, this map is given by the composite
